[2] It is remarkable that on almost all of these occasions the locality pitched upon has been, either at the time or soon after, ravaged by locusts, which the birds greedily devour Another fact worthy of attention is that they are often observed to affect trees or shrubs bearing rose coloured flowers, as *Nerium oleander* and *Robinia viscosa*, among the blossoms of which they themselves may easily escape notice, for their plumage is rose-pink and black shot with blue

lord high steward to sit judicially in the court of claims to hear and determine all claims to render services of grand serjeanty to the king or queen at his or her coronation Since the accession of the house of Tudor, however, this function has generally been discharged by a specially appointed commission, or a committee of the privy council According to the tradition once current among lawyers and antiquaries, the steward of England was, under the Norman and Angevin kings, the second personage in the realm, the viceroy in the absence and the chief minister in the presence of the sovereign Coke says, on the more than doubtful authority of an ancient manuscript, that his office was to superintend under the king and next after the king the whole kingdom and all the ministers of the law within the kingdom in time of both peace and war But of this there is no satisfactory evidence It is not improbable that the steward of England may for a short period after the Conquest have occupied a position analogous to that of the Saxon heah-gerefa or that of the Norman seneschal, or of the two in combination But, as Stubbs points out, the chief minister and occasional viceroy, either alone or with others, of the Conqueror and his earlier successors was the person to whom the historians and the later constitutional writers give the name of justiciarius with or without the prefix "summus" or "capitalis" He adds that most likely the Norman seneschalship was the origin of the English justiciarship, that under Henry II the seneschal of Normandy receives the name of justiciar, and that it is only in the same reign that the office in England acquires the exclusive right to the definite name of "summus" or "capitalis justitiarius" or "justitiarius totius Angliæ" But whatever may have been his original condition the steward had been by that time at the latest eclipsed in his most important functions by the justiciar, and he makes, as Stubbs observes, in his official capacity no great figure in English history By the reign of Henry II at any rate all connexion between the stewardship and the justiciarship had come to an end, and, while the second retained its authority unimpaired until its extinction, the first became a grand serjeanty, primarily annexed to the barony of Hinckley, it is said, and afterwards to the earldom of Leicester On the attainder of Simon de Montfort the earldom and stewardship were forfeited, and both were granted by Edward I to his brother Edmund Plantagenet, earl of Lancaster, from whom they descended to the daughter and eventual heiress of Henry Plantagenet, duke of Lancaster She was the first wife of John of Gaunt and the mother of Henry IV On the accession of her son to the throne they became merged in the crown, from which period the stewardship has been revived only *hac vice* from time to time as occasion required It is indeed to John of Gaunt that the pre-eminent position accorded to the office since the end of the 14th century is really due It emerged from the comparative obscurity in which it had rested for nearly three hundred years as soon as he became the tenant of it by courtesy in right of his deceased wife As far as any records show to the contrary he was the first steward of England who took part in the coronation of a king or queen, and he was certainly the first steward of England who sat in the court of claims or who presided at a trial by the House of Lords It seems to have been by him also that the precedence of the stewardship before all the other great offices of state was secured, a restoration or augmentation of rank which is the more remarkable in that the steward of Scotland gave place to the chamberlain and the seneschal of Ireland gave place to the constable of the two kingdoms respectively John of Gaunt may be regarded, in fact, as the creator of the lord high stewardship and all its privileges and prerogatives as they have existed from his days to our own

Lord great chamberlain

The lord great chamberlain of England ranks as the sixth great officer of state Whenever the sovereign attends the palace of Westminster the keys are delivered to him, and he is for the time in command of the building At the opening or closing of the session of parliament by the sovereign in person he disposes of the sword of state to be carried by any peer he may select, and walks himself in the procession on the right of the sword of state, a little before it and next to the sovereign He assists at the introduction of all peers into the House of Lords on their creation, and at the homage of all bishops after their consecration At a coronation he receives the regalia from the dean and chapter of Westminster, and distributes them to the personages who are to bear them in the ceremony On that day it is his duty to carry the sovereign his shirt and wearing apparel before he rises and to serve him with water to wash his hands before and after dinner The chamberlain was originally a financial officer, his work, Stubbs says, was rather that of auditor or accountant than that of treasurer, he held a more definite position in the household than most of the other great officers, "and in the judicial work of the country he was only less important than the justiciar" The office was hereditary in the Veres, earls of Oxford, from the reign of Henry I to the reign of Charles I, when it passed through an heiress to the Berties, Lords Willoughby de Eresby, and afterwards earls of Lindsey and dukes of Ancaster, and from the Berties it was transmitted through coheiresses to the present inheritors of the dignity The Stuarts, dukes of Lennox, were hereditary great chamberlains of Scotland in the 16th and 17th centuries The office on their extinction was granted by Charles II to James, duke of Monmouth and Buccleuch, on whose attainder it passed to Charles, duke of Richmond and Lennox, by whom it was surrendered to the crown in 1703

Lord high constable

The lord high constable of England ranks as the seventh of the great officers of state His office is called out of abeyance for coronations alone, when it is his duty to assist in the reception of the regalia from the dean and chapter of Westminster, and during the coronation banquet to ride into Westminster Hall on the right hand of the champion The constable was originally the commander of the royal armies and the master of the horse He was also one of the judges of the court of chivalry or court of honour The constableship was granted as a grand serjeanty with the earldom of Hereford by the empress Maud to Milo of Gloucester, and was carried by his heiress to the Bohuns, earls of Hereford and Essex Through a coheiress of the Bohuns it descended to the Staffords, dukes of Buckingham, and on the attainder of Edward Stafford, third duke of Buckingham, in the reign of Henry VIII it became merged in the crown The Lacys and Verduns were hereditary constables of Ireland from the 12th to the 14th century, and the Hays, earls of Erroll, have been hereditary constables of Scotland from early in the 14th century until the present time

Earl marshal

The earl marshal of England ranks as the eighth of the great officers of state He is the head of the college of arms, and has the appointment of the kings-of-arms, heralds, and pursuivants at his discretion He attends the sovereign in opening and closing the session of parliament, walking opposite to the lord great chamberlain on his or her right hand It is his duty to make arrangements for the order of all state processions and ceremonials, especially for coronations and royal marriages and funerals Like the lord high constable he rides into Westminster Hall with the champion after a coronation, taking his place on the left hand, and with the lord great chamberlain he assists at the introduction of all newly-created peers into the House of Lords The marshal appears in the feudal

armies to have been in command of the cavalry under the constable, and to have in some measure superseded him as master of the horse in the royal palace. He exercised joint and co-ordinate jurisdiction with the constable in the court of chivalry, and afterwards became the sole judge of that tribunal. The marshalship of England was made hereditary in the Clares and Marshals, earls of Pembroke, in the reign of Stephen or Henry II., and through a co-heiress passed to the Bigots, earls of Norfolk, and by Roger Bigot, fifth earl of Norfolk, it was surrendered with his other dignities to Edward I. It was granted by Edward II. to his brother Thomas of Brotherton, earl of Norfolk, and, after it had been variously disposed of by Edward III., was by Richard II. erected into an earldom and conferred on Thomas Mowbray, duke of Norfolk, who was the great-grandson and heir of Thomas of Brotherton. One of the coheiresses of the Mowbrays was the mother of John Howard, duke of Norfolk, who was created earl marshal by Richard III. After several attainders and partial restorations in the reigns of the Tudors and the Stuarts, the earl marshalship was finally entailed by Charles II. on the male line of the Howards, with many specific remainders and limitations, under which settlement it has regularly descended to the present duke of Norfolk. The Clares and Marshals, earls of Pembroke, and the Lords Morley appear to have been hereditary marshals of Ireland from the invasion of the island until the end of the 15th century. The Keiths were Earls Marischal of Scotland from the institution of the office by James II. in 1458 until the attainder of George, the tenth earl, in 1716.

On the subject of the great offices of state generally, see Stubbs, *Constitutional History*, ch. xi.; Freeman, *Norman Conquest*, ch. xxiv.; Gneist, *Constitution of England*, ch. xvi., xxxv., and liv.; also Gibbon, *Decline and Fall*, ch. liii.; and Bryce, *Holy Roman Empire*, ch. xiv. (F. DR.)

STATEN ISLAND, an island of New York State, forming, with some adjacent islands, Richmond county, with a population of 38,991 in 1880, is situated about 5 miles south of New York city, from which it is separated by New York Bay, while the Narrows, commanded by Forts Wadsworth and Tompkins and a line of water-batteries, separate it from Long Island on the north east, Staten Island Sound from New Jersey on the west, and Newark Bay and the Kill van Kull from the same State on the north. It is of an irregular triangular shape, its greatest length being about 13 miles, its greatest breadth about 8, and the total area $58\frac{1}{2}$ square miles. The surface is gently undulating, but a range of hills attaining 310 feet in height extends across the northern portion. Iron ore is found. The island contains many detached villa residences of persons in business in New York. On an artificial island off the east shore is the New York quarantine establishment, and Staten Island is the seat of the "Sailors' Snug Harbour," a retreat for superannuated seamen. Steam ferries ply half-hourly to New York, and on the island there is a railway line from Tompkinsville to Tottenville.

STATE PAPERS. See RECORDS, PUBLIC.

STATES OF THE CHURCH, or PAPAL STATES (Ital. *Stato della Chiesa*, *Stato Pontificio*, *Stato Romano*, *Stato Ecclesiastico*; Fr. *États de l'Église*, *Pontificat Souverain de Rome*, &c.; Germ. *Kirchenstaat*; in ecclesiastical Latin often *Patrimonium Sancti Petri*), that portion of central Italy which, previous to the unification of the kingdom, was under the direct government of the see of Rome. The territory stood at the close as in the annexed table.

With the exception of Benevento, surrounded by the Neapolitan province of Principato Ulteriore, and the small state of Pontecorvo, enclosed within the Terra di Lavoro, the States of the Church formed a compact territory, bounded on the N.W. by the Lombardo-Venetian kingdom, on the N.E. by the Adriatic, on the S.E. by the kingdom of Naples, on the S.W. by the Mediterranean, and on the W. by the grand-duchy of Tuscany and the duchy of Modena. On the Adriatic the coast extended 140 miles, from the mouth of the Tronto (Truentus) to the southern mouth of the Po, and on the Tyrrhenian Sea 130 miles, from 41° 20′ to 42° 22′ N. lat. See vol. xiii. Plate VI.

		Area in English Square Miles	Population in 1853
	Comarca of Rome	1752.8	326,509
Legations	Bologna	1359.2	375,631
	Ferrara	1094	244,524
	Forlì	718.8	218,433
	Ravenna	701.5	175,994
	Urbino, with Pesaro	1414.6	257,751
	Velletri	571.3	62,013
Delegations	Ancona	441.8	176,519
	Macerata	895	243,104
	Camerino	320	42,991
	Fermo	335.7	110,321
	Ascoli	476.3	91,916
	Perugia	1555.5	234,533
	Spoleto	1175.9	135,029
	Rieti	531.7	73,683
	Viterbo	1158.9	128,324
	Orvieto	316.6	29,047
	Cività Vecchia	380	20,701
	Frosinone, with Pontecorvo	739.9	154,559
	Benevento	61.3	23,176
		16,000.8	3,124,758

The divisions shown above were adopted on December 21, 1827, the legations being ruled by a cardinal and the delegations by a prelate. Previously the several districts formally recognized were Latium, the Marittima (or sea-board) and Campagna, the Patrimony of Saint Peter, the duchy of Castro, the Orvietano, the Sabina, Umbria, the Perugino, the March of Ancona, Romagna, the Bolognese, the Ferrarese, and the duchies of Benevento and of Pontecorvo.

The question of the origin of the territorial jurisdiction of the pope has been treated under POPEDOM (vol. xix. p. 495). With the moral and ecclesiastical decay of the papacy in the 9th and 10th centuries much of its territorial authority slipped from its grasp, and by the middle of the 11th century its rule was not recognized beyond Rome and the immediate vicinity. By the treaty of Sutri (February 1111) Paschal II. was compelled by the emperor Henry V. to surrender all the possessions and royalties of the church, but this treaty was soon afterwards repudiated, and by the will of Matilda, countess of Tuscany, the papal see was enabled to lay claim to new territories of great value. By the capitulation of Neuss (1201) Otto IV. recognized the papal authority over the whole tract from Radicofani in Tuscany to the pass of Ceperano on the Neapolitan frontier—the exarchate of Ravenna, the Pentapolis, the March of Ancona, the bishopric of Spoleto, Matilda's personal estates, and the countship of Brittenoro, but a good deal of the territory thus described remained for centuries an object of ambition only on the part of the popes. The actual annexation of Ravenna, Ancona, Bologna, Ferrara, &c., dates from the 16th century. The States of the Church were of course submerged for a time by the ground-swell of the French Revolution, but they appeared again in 1814. In 1849 they received a constitution. On the formation of the kingdom of Italy in 1860 they were reduced to the Comarca of Rome, the legation of Velletri, and the three delegations of Viterbo, Cività Vecchia, and Frosinone, and in 1870 they disappeared from the political map of Europe.

STATICS. See MECHANICS.

STATIONERY. Under the name of stationery are embraced all writing materials and implements, together with the numerous appliances of the desk and of mercantile and commercial offices. In addition to these, the term fancy stationery covers a miscellaneous assemblage of leather and other goods, such as pocket-books, purses, bags, card-cases, and many kindred objects which cannot be classified. The principal articles and operations of the stationery trade are dealt with in detail under separate headings—BOOKBINDING, EMBOSSING, INK, LITHOGRAPHY,

PAPER, PEN, PENCIL, SEALING-WAX, &c, but in connexion with the separate industry of a commercial stationer there are a number of special operations and machines to which brief allusion may be made

Paper Ruling—The ruling of blue and other coloured lines is usually done on a self-feeding machine provided with as many ruling pens as there are lines to be made, and these fixed in parallel order at intervals the width of the ruled spaces The pens consist of grooved slips of sheet brass coming to a fine point which in their upper part are covered by a sheet of felt saturated with a flowing ink, whence each pen obtains the supply required for tracing its line The paper is carried forward by endless tapes or threads which pass around cylinders In a recent form of machine the rulers consist of metal disks with thin edges, which take up printing ink from an india rubber cylinder, and print the lines on the paper as it passes around a revolving cylinder

Paper-Folding machinery is used for numerous purposes in the stationery trade, apart from its application to the folding of sheets for the bookbinder Devices for folding come most prominently forward in connexion with the envelope manufacture, an industry which received an enormous development by the introduction of uniform postage rates In envelope-making the folding is commonly associated with gumming, and sometimes with embossing, in the same system of machinery The first efficient automatic machine for envelope manufacture was devised by Edwin Hill and Warren de la Rue, and by them patented in 1845 Many forms of envelope folding and gumming machine now exist In making envelopes the blanks are first cut out by shaped cutters or punches acting at one stroke on a thickness of from 200 to 300 sheets of paper These blanks in the latest form of machine are gummed by a pad which takes gum from a roller and presses it on the edges of the paper, just as printing ink is received from cylinders and pressed on paper in printing The gummed surface of the pad lifts each blank separately, places it under a plunger, which, descending, passes it to folders, whence it is delivered into a clip in an endless band of considerable length The envelopes are delivered into the clips in the band at the rate of about 100 to 150 per minute

Perforating and *Punching* give rise to a range of machines of varied form and complexity The idea of perforating paper so as to allow of the ready detaching of portions by tearing was conceived and patented in 1848 by Mr Henry Archer Of such utility was Mr Archer's conception deemed by the post-office authorities as a convenience for detaching stamps from sheets that in 1853 he was awarded £4000 for his patent rights The applications of perforation are now very numerous, but its value still remains most obvious in connexion with the detachment of adhesive stamps from sheets

Numbering and *Paging* constitute another series of stationery operations, for which ingenious machines have been devised For consecutive numbering a series of printing disks are employed, on the periphery of which the series of digits 1 to 0 are raised The outer disk moves a number after each impression, the second disk moves once in ten times, and so on, thus automatically imprinting consecutive numbers up to the limit of the disks on the machine Such a machine prints only on one side of the paper, and where the numbering is required on both sides the disks must be geared to move two places, numbering only odd or even numbers, two printings being thus required For printing right and left consecutively an endless band machine is used, which prints alternately below and above for the two sides of the sheet

STATISTICS The word "statistic" is derived from the Latin *status*, which, in the so-called Middle Ages, had come to mean a "state" in the political sense "Statistic," therefore, originally denoted inquiries into the condition of a state Since the beginning of the 18th century the denotation of the word has been extended so as to include subjects only indirectly connected with political organizations, while at the same time the scope of the investigations it implies has become more definite, and at the present day may be said, for practical purposes, to be fixed, though there are still controversies as to the position of statistical studies in relation to other departments of scientific procedure

History—The origin of what is now known as "statistic" (Ger *Die Statistik*, Fr *La Statistique*, Ital *Statistica*) can only be referred to briefly here As M Maurice Block has observed in commencing his admirable treatise, "it is no exaggeration to say that statistic has existed ever since there were states" For the first administrative act of the first regular Government was probably to number its fighting men, and its next to ascertain with some degree of accuracy what amount of taxation could be levied on the remainder of the community As human societies became more and more highly organized, there can be no doubt that a very considerable body of official statistics must have come into existence, and been constantly used by statesmen, solely with a view to administration The Romans, who may be described as the most business-like people of antiquity, were careful to obtain accurate information regarding the resources of the state, and they appear to have carried on the practice of taking the census, a very comprehensive statistical operation, with a regularity which has hardly been surpassed in modern times As to the efficiency of the work done we have unfortunately very little information, but those who are curious on the subject may be referred to an article by Dr Hildebrand, entitled "Die amtliche Bevolkerungsstatistik im alten Rom," printed in the *Jahrbuch fur Nationalokonomie und Statistik*, 1866, p 82

Statistics, or rather the material for statistics, therefore existed at a very early period, but it was not until within the last three centuries that systematic use of the information available began to be made for purposes of investigation and not of mere administration According to M Block, the earliest work in which facts previously known only to Government officials were published to the world was a volume compiled by Francesco Sansovino, entitled *Del Governo et Amministrazione di Diversi Regni et Republiche*, which was printed in Venice and bears the date 1583 Other works of a similar kind were published towards the end of the 16th century in Italy and France Regarding these and other early books on the subject reference may be made to Fallati's *Einleitung in die Wissenschaft der Statistik*, Dr G B Salvioni's preface and notes to his translation into Italian of Dr Mayr's work on statistics, and other authors mentioned at the close of this article

Works on state administration and finance continued to be published during the first half of the 17th century, and the tendency to employ figures, which were hardly used at all by Sansovino, became more marked, especially in England, where the facts connected with "bills of mortality" had begun to attract attention.

In the year 1660 Hermann Conring, "professor of medicine and politics," a rather odd combination, in the university of Helmstadt, was in the habit of giving lectures in which he analysed and discussed the circumstances existing in various countries, in so far as they affected the happiness of the inhabitants. Conring's example was followed by other writers, in Germany and elsewhere, to whom reference is made by Block (*Traité*, pp 5, 6) and Haushofer (*Lehr- und Handbuch*, p 10, note)

The best-known member of the "descriptive" school was Achenwall (1719–1772), who is sometimes spoken of as "the father of modern statistics," but, as his procedure was essentially the same as that of Conring, though it was carried out more fully, the title has not been unanimously granted It is generally admitted, however, that Achenwall's work gave a great impulse to the pursuit of the studies which are now included under the title of statistics He called his book *Staatsverfassung der europaischen Reiche* in the first two editions (1749, 1752), meaning "Constitution of the States of Europe" Subsequently he added "vornehmsten" and then "heutigen" before "europaischen," evidently with the desire of bringing his work, which may be regarded as the germ of such volumes as the *Statesman's Year-Book*, "up to date" Achenwall is usually credited with being the first writer who made use of the word "statistics," which he applied to his collection of "noteworthy matters regarding the state"

(*Staatsmerkwürdigkeiten*), but the claim has been disputed by M Block, who points out that the term *collegium statisticum* had been previously employed by Schmeitzel, a follower of Conring, whose lectures at Jena were no doubt attended by Achenwall

In any case statistics, in the modern sense of the word, did not really come into existence until the publication by J P Sussmilch, a Prussian clergyman, of a work entitled *Die gottliche Ordnung in den Veränderungen des Menschlichen Geschlechts aus dem Geburt, dem Tode, und der Fortpflanzung desselben erwiesen* In this book a systematic attempt was made to make use of a class of facts which up to that time had been regarded as belonging to "political arithmetic," under which description some of the most important problems of what modern writers term "vital statistics" had been studied, especially in England Sussmilch had arrived at a perception of the advantage of studying what Quetelet subsequently termed the "laws of large numbers" He combined the method employed by the Conring-Achenwall school of "descriptive statistics," whose works were not unlike modern school-books of geography, with that of the "political arithmeticians," who had confined themselves to investigations into the facts regarding mortality and a few other similar subjects, without much attempt at generalizing from them

Political arithmetic had come into existence in England in the middle of the 17th century, or about the time when Conring was instructing the students of Helmstadt The earliest example of this class of investigation is the work of Captain John Graunt of London, entitled *Natural and Political Annotations made upon the Bills of Mortality*, which was first published in 1666 This remarkable work, which dealt with mortality in London only, ran through many editions, and the line of inquiry it suggested was followed up by other writers, of whom the most distinguished was Sir William Petty, whose active mind was naturally attracted by the prospect of making use of a new scientific method in the class of speculations which occupied him Sir William was the first writer to make use of the phrase which for nearly a century afterwards was employed to describe the use of figures in the investigation of the phenomena of human society He called his book on the subject, which was published in 1683, *Five Essays in Political Arithmetick* Other writers, of whom Halley, the celebrated mathematician and astronomer, was one, entered on similar investigations, and during the greater part of the 18th century the number of persons who devoted themselves to "arithmetical" inquiries into problems of the class now known as statistical was steadily increasing Much attention was given to the construction of tables of mortality, a subject which had a great attraction for mathematicians, who were eager to employ the newly-discovered calculus of probabilities on concrete problems Besides Halley, De Moivre, Laplace, and Euler busied themselves with this branch of study Attempts were also made to deal with figures as the basis of political and fiscal discussion by Arthur Young, Hume, and other historical writers, as well as by the two Mirabeaus

It is now necessary to return to Sussmilch, who, as already mentioned, endeavoured to form a general theory of society, based on what were then termed "arithmetical" premisses, treated nearly on the lines laid down by Achenwall In modern language, he made use of quantitative aggregate-observation as an instrument of social inquiry It is true he did not enter on his investigation with an "open mind" He desired to support a foregone conclusion, as the title of his work already mentioned shows But nevertheless his work was a most valuable one, since it pointed out a road which others who had no desire to procure evidence in favour of a particular system of thought were not slow to follow M Block makes the following remarks on the influence exercised on his contemporaries by the work of Sussmilch —"If the author of the *Gottliche Ordnung* had been a professor his influence would have been much greater than it was In maintaining that the movement of population is subject to law, that there is a regularity in the recurrence of such phenomena which allows of their being foreseen, he cast into the public mind a leaven which has evidently contributed to the progress of science" Although for many years after the appearance of Sussmilch's book there was a good deal of resistance to the introduction of "arithmetic" as the coadjutor of moral and political investigations, yet, practically there was a tacit admission of the usefulness of figures, even by the chiefs of the so-called "descriptive" school On the other hand Sussmilch's success was the origin of a "mathematical" school of statisticians, some of whom carried their enthusiasm for figures so far that they refused to allow any place for mere "descriptions" at all These two schools have now coalesced, each admitting the importance of the point of view urged by the other They were, however, still perceptibly distinct even as late as 1850, and the ignorant hostility with which many people even among the cultivated classes still regard statistical inquiries into the nature of human society may be regarded as a survival of the much stronger feeling which showed itself among "orthodox" professors of law and economics on the publication of Süssmilch's treatise

M Block is of opinion that the descriptive school, by whom figures are regarded merely as accessories to and illustrations of the text, would have maintained its position even now but for the establishment of official statistical offices and the influence of the great Belgian Quetelet Quetelet's work was certainly "epoch-making" in a far higher degree than that of any of his predecessors To the impulse created by him must be attributed the foundation in 1835 of the Statistical Society of London, a body which, though it has contributed little to the discussion of the theory of statistics, has had a considerable and very useful influence on the practical work of carrying out statistical investigations in the United Kingdom and elsewhere Quetelet's works were numerous and multifarious, but his most important contribution to the growth of statistical inquiry was his investigation of the theory of probabilities as applied to the "physical and social" sciences, contained in a series of letters to the duke of Saxe-Coburg and Gotha, and published in 1846 Quetelet was above all things an exponent of the "laws of large numbers" He was especially fascinated with the tendency to relative constancy of magnitude displayed by the figures of moral statistics, especially those of crime, which inspired him with a certain degree of pessimism His conception of an average man (*l'homme moyen*) and his disquisition on the "curve of possibility" were most important contributions to the technical development of the statistical method, though, as M Block observes, their value may have been somewhat exaggerated by subsequent writers (Block, ch i p 16, and ch v p. 112 *sq.*) It is not possible to enter at length into Quetelet's work in connexion with statistical science At the close of this article will be found a list including those of his works which are likely to be of use to students of statistics.

The influence exercised by Quetelet on the development of statistics is clearly seen from the fact that, though there is still considerable controversy among statisticians, the old controversy between the "descriptive" and arithmetical schools has disappeared, or perhaps we should say has been transformed into a discussion of another kind, the question now at issue being whether there is a science

of statistics as well as a statistical method It is true that a few books were published between 1830 and 1850 in which the politico-geographical description of a country is spoken of as "statistics," which is thus distinguished from "political arithmetic" The title of Knies's great work, *Die Statistik als selbständige Wissenschaft* (Cassel, 1850), is especially noteworthy as showing that the nature of the controversy was changing The opponents of Sussmilch maintained that "political arithmetic" ought not to be spoken of as statistics at all They clung to the conceptions of Conring and Achenwall, to whom "statistics" represented "Staatenkunde" or "Staatszustandskunde," or, as Herzberg, one of Achenwall's followers, called it, "die Kenntniss von der politischen Verfassung der Staaten" Knies claimed that the really "scientific" portion of statistics consisted of the figures employed As Haushofer says, "his starting point is political arithmetic"

Some eminent statisticians of the latter half of the present century agree with Knies, but the majority of the modern writers on the theory of statistics have adopted a slightly different view, according to which statistics is at once a *science* relating to the social life of man and a *method of investigation* applicable to all sciences This view is ably maintained by Mayr, Haushofer, Gabaglio, and Block, who may be taken to represent the opinions held by the majority of statisticians on the Continent

Having dealt as far as was possible, within the limits of this article, with the history of statistics, we may here enter a little more minutely into the views of the existing Continental school This is all the more necessary because, singular to say, there has been no systematic exposition of the subject in England Isolated dicta have been furnished by high authorities, such as the late Dr W A Guy, Prof Ingram, Sir Rawson W Rawson, Mr Robert Giffen, and to some extent also by John Stuart Mill, Buckle, Sir George Cornewall Lewis, and other historical and economic writers There are also monographs on particular points connected with the *technique* of statistical investigation, such as the contribution made by Mr F Y Edgeworth to the discussions at the jubilee of the Statistical Society in 1885, and some of the observations contained in a paper by Mr Patrick Geddes, entitled *An Analysis of the Principles of Economics*, read before the Royal Society of Edinburgh in 1884 Prof Foxwell has also lectured on the subject of statistics in his capacity of Newmarch lecturer at University College, London But there has been no attempt to deal with the subject in a systematic way The practice of statistical inquiry, on the other hand, has been carried on in England with a high degree of success

With regard to the few invasions of the domain of theory attempted by English writers, it may be observed that the authorities above mentioned are not unanimous Dr Guy as well as Sir Rawson Rawson, who handled the subject with great ability at the jubilee meeting of the London Statistical Society in June 1885, both claim that statistics is to be regarded as an independent science, apart from sociology, while Prof Ingram, who presided over Section F at the Dublin meeting of the British Association in 1878, maintained that statistics cannot occupy a position co-ordinate with that of sociology, and went on to say that they "constitute only one of the aids or adminicula of science" Mr Giffen has also expressed himself adversely to the Continental doctrine that there is an independent science of statistics, and this opinion appears to be the correct one, but, as Dr Guy and Sir Rawson Rawson have the support of the great body of systematic teaching emanating from distinguished Continental statisticians in support of their view, while their opponents have so far only the *obiter dicta* of a few eminent men to rely upon, it appears needful to examine closely the views held by the Continental authorities, and the grounds on which they are based

The clearest and shortest definition of the science of statistics as thus conceived is that of M Block, who describes it as "la science de l'homme vivant en société en tant qu'elle peut être exprimée par les chiffres" He proposes to give a new name to the branch of study thus defined, namely, "Demography" Mayr's definition is longer He defines the statistical science as "die systematische Darlegung und Erörterung der thatsächlichen Vorgänge und der aus diesen sich ergebenden Gesetze des gesellschaftlichen menschlichen Lebens auf Grundlage quantitativer Massenbeobachtungen" (the systematic statement and explanation of actual events, and of the laws of man's social life that may be deduced from these, on the basis of the quantitative observation of aggregates) Gabaglio's view is practically identical with those adopted by Mayr and Block, though it is differently expressed He says "statistics may be interpreted in an extended and in a restricted sense In the former sense it is a method, in the latter a science As a science it studies the actual social-political order by means of mathematical induction"

This discussion regarding the nature of statistics is to a large extent a discussion about names There is really no difference of opinion among statistical experts as to the subject-matter of statistics, the only question being—Shall statistics be termed a science as well as a method? That there are some investigations in which statistical procedure is employed which certainly do not belong to the domain of the supposed statistical science is generally admitted But, as already shown, an attempt has been made to claim that the phenomena of human society, or some part of those phenomena, constitute the subject-matter of an independent statistical science It is not easy to see why this claim should be admitted There is no reason either of convenience or logic why the use of a certain scientific method should be held to have created a science in one department of inquiry, while in others the said method is regarded merely as an aid in investigation carried on under the superintendence of a science already in existence It is impossible to get over the fact that in meteorology, medicine, and other physical sciences statistical inquiries are plainly and obviously examples of the employment of a method, like microscopy, spectrum analysis, or the use of the telescope Why should the fact of their employment in sociology be considered as authorizing the classification of the phenomena thus dealt with to form a new science?

The most effective argument put forward by the advocates of this view is the assertion that statistics are merely a convenient aid to investigation in the majority of sciences, but are the sole method of inquiry in the case of sociology Dr Mayr especially (*Gesetzmässigkeit*, &c, p 14 *sq*) makes use of this argument, and illustrates it with his usual ability, but his reasoning is very far from being conclusive When, indeed, it is tested by reference to the important class of social facts which are named economic, it becomes obvious that the argument breaks down Economics is a branch—the only scientifically organized branch—of sociology, and statistics are largely used in it, but no one, so far as we are aware, has proposed to call economics a department of statistical science Sir Rawson W Rawson, it is true, has boldly proposed to throw over the term "sociology" altogether, and to describe the study of man in the social state as "statistics," but common usage is too firmly fixed to make this alteration of nomenclature practicable even if it were desirable The existence of the works of Mr Herbert Spencer and Dr Schäffle alone would render the attempted alteration abortive

Although, however, the above considerations forbid the acceptance of the Continental opinion that the study of man in the social state is identical with statistics, it must be admitted that without statistics the nature of human society could never become known. For society is an aggregate, or rather a congeries of aggregates. Not only that, but the individuals composing these aggregates are not in juxtaposition, and what is, from the sociological point of view, the same aggregate or organ of the "body politic" is not always composed of the same individuals. Constancy of social form is maintained concurrently with the most extensive changes in the collocation and identity of the particles composing the form. A "nation" is really changed, so far as the individuals composing it are concerned, every moment of time by the operation of the laws of population. But the nation, considered sociologically, remains the same in spite of this slow change in the particles composing it, just as a human being is considered to be the same person year by year, although year by year the particles forming his or her body are constantly being destroyed and fresh particles substituted. Of course the analogy between the life of a human being and the life of a human community must not be pressed too far. Indeed, in several respects human communities more nearly resemble some of the lower forms of animal life than the more highly organized forms of animal existence. There are organisms which are fissiparous, and when cut in two form two fresh independent organisms, so diffused is the vitality of the original organism; and the same phenomenon may be observed in regard to human communities.

Now the only means whereby the grouping of the individuals forming a social organism can be ascertained, and the changes in the groups year by year observed, is the statistical method. Accordingly the correct view seems to be that it is the function of this method to make perceptible facts regarding the constitution of society on which sociology is to base its conclusions. It is not claimed, or ought not to be claimed, that statistical investigation can supply *the whole* of the facts a knowledge of which will enable sociologists to form a correct theory of the social life of man. The statistical method is essentially a mathematical procedure, attempting to give a quantitative expression to certain facts; and the resolution of differences of quality into differences of quantity has not yet been effected even in chemical science. In sociological science the importance of differences of quality is enormous, and the effect of these differences on the conclusions to be drawn from figures is sometimes neglected, or insufficiently recognized, even by men of unquestionable ability and good faith. The majority of politicians, social "reformers," and amateur handlers of statistics generally are in the habit of drawing the conclusions that seem good to them from such figures as they may obtain, merely by treating as homogeneous quantities which are heterogeneous, and as comparable quantities which are not comparable. Even to the conscientious and intelligent inquirer the difficulty of avoiding mistakes in using statistics prepared by other persons is very great. There are usually "pitfalls" even in the simplest statistical statement, the position and nature of which are known only to the persons who have actually handled what may be called the "raw material" of the statistics in question; and in regard to complex statistical statements the "outsider" cannot be too careful to ascertain from those who compiled them as far as possible what are the points requiring elucidation.

The Statistical Method.—This method is a scientific procedure (1) whereby certain phenomena of aggregation not perceptible to the senses are rendered perceptible to the intellect, and (2) furnishing rules for the correct performance of the quantitative observation of these phenomena. The class of phenomena of aggregation referred to includes only such phenomena as are too large to be perceptible to the senses. It does not, *e.g.*, include such phenomena as are the subject-matter of microscopy. Things which are very large are often quite as difficult to perceive as those which are very small. A familiar example of this is the difficulty which is sometimes experienced in finding the large names, as of countries or provinces, on a map. Of course the terms "large," "too large," "small," and "too small" must be used with great caution, and with a clear comprehension on the part of the person using them of the standard of measurement implied by the terms in each particular case. A careful study of the first few pages of De Morgan's *Differential and Integral Calculus* will materially assist the student of statistics in attaining a grasp of the principles on which standards of measurement should be formed. It is not necessary that he should become acquainted with the calculus itself, or even possess anything more than an elementary knowledge of mathematical science, but it is essential that he should be fully conscious of the fact that "large" and "small" quantities can only be so designated with propriety by reference to a common standard.

Sources whence Statistics are Derived.—The term "statistics" in the concrete sense means systematic arrangements of figures representing "primary statistical quantities." A primary statistical quantity is a number obtained from numbers representing phenomena, with a view to enable an observer to perceive a certain other phenomenon related to the former as whole to parts. They represent either a phenomenon of existence at a given point of time or a phenomenon of accretion during a given period. As examples may be mentioned the number of deaths in a given district during *a given time*, the number of pounds sterling received by the London and North Western Railway during a given time, and the number of "inches of rain" that fell at Greenwich during a given time. Other examples are the number of tons of pig-iron lying in a particular store at *a given date*, the number of persons residing (the term "residing" to be specially defined) in a given territory at a given date, and the number of pounds sterling representing the "private deposits" of the Bank of England at a given date.

Primary Statistical Quantities are the result of labours carried on either (A) by Governments or (B) by individuals or public or private corporations.

A. *Government Statistics.*—(1) A vast mass of statistical material of more or less value comes into existence automatically in modern states in consequence of the ordinary administrative routine of departments. To this class belong the highly important statistical information published in England by the registrar-general, the returns of pauperism issued by the Local Government Board, the reports of inspectors of prisons, factories, schools, and those of sanitary inspectors, as well as the reports of the commissioners of the customs, and the annual statements of trade and navigation prepared by the same officials. There are also the various returns compiled and issued by the Board of Trade, which is the body most nearly resembling the statistical bureaus with which most foreign Governments are furnished. Most of the Government departments publish some statistics for which they are solely responsible as regards both matter and form, and they are very jealous of their right to do so, a fact which is to some extent detrimental to that uniformity as to dates and periods which should be the ideal of a well-organized system of statistics. Finally may be mentioned the very important set of statistical quantities known as the budget, and the statistics prepared and published by the commissioners of inland revenue, by the post office, and by the national debt commissioners. All these sets of primary statistical quantities arise out of the ordinary work of departments of the public service. Many of them have been in existence, in some form or other, ever since a settled Government existed in the country. There are records of customs receipts at London and other ports of the time of Edward III., covering a period of many years, which leave nothing to be desired in point of precision and uniformity. It may be added that many of these sets of figures are obtained in much the same form by all civilized Governments, and that it is often possible to compare the figures relating to different countries, and thus obtain evidence as to the sociological phenomena of each, but in regard to others there are differences which make comparison difficult.

(2) Besides being responsible for the issue of what may be called administration statistics, all Governments are in the habit of ordering from time to time special inquiries into special subjects

of interest, either to obtain additional information needful for administrative purposes, or, in countries possessed of representative institutions, to supply statistics asked for by parliaments or congresses. It is not necessary to refer particularly to this class of statistical information, except in the case of the census. This is an inquiry of such great importance that it may be regarded as one of the regular administrative duties of Governments, though as the census is only taken once in a series of years it must be mentioned under the head of occasional or special inquiries undertaken by Governments. In the United Kingdom the work is done by the registrars general who are in office when the period for taking the census comes round. On the Continent the work is carried out by the statistical bureaus of each country,—except France, where it is under the supervision of the minister of the interior. For further information on this subject reference may be made to the excellent chapter in M. Maurice Block's *Traité* entitled "Recensement." See also "Instructions to the Superintendent Registrar of Births and Deaths as to his duties in taking the Census," 1871, also CENSUS, vol. v. p. 334 *sq.*

B. The primary statistical quantities for which individuals or corporations are responsible may be divided into three categories.

(1) Among those which are compiled in obedience to the law of the land are the accounts furnished by municipal corporations, by railway, gas, water, banking, insurance, and other public companies making returns to the Board of Trade, by trades unions, and by other bodies which are obliged to make returns to the registrar of friendly societies. The information thus obtained is published in full by the departments receiving it, and is also furnished by the companies themselves to their proprietors or members.

(2) An enormous mass of statistical information is furnished voluntarily by public companies in the reports and accounts which, in accordance with their articles of association, are presented to their proprietors at stated intervals. With these statistics may be classed the figures furnished by the various trade associations, some of them of great importance, such as Lloyd's, the London Stock Exchange, the British Iron Trade Association, the London Corn Exchange, the Institute of Bankers, the Institute of Actuaries, and other such bodies too numerous to mention.

(3) There are cases in which individuals have devoted themselves with more or less success to obtaining original statistics on special points. The great work done by Messrs Behm and Wagner in arriving at an approximate estimate of the population of the earth does not belong to this category, though its results are really primary statistical quantities. Many of these results have not been arrived at by a direct process of enumeration at all, but by ingenious processes of inference. It need hardly be said that it is not easy for individuals to obtain the materials for any primary statistical quantity of importance, but it has been done in some cases with success.

Operations Performed on Primary Statistical Quantities.—Only a brief description of matters connected with the *technique* of the statistical method can be given in this article. In order to form statistics properly so called the primary statistical quantities must be formed into tables, and in the formation of these tables lies the art of the statistician. It is not a very difficult art when the principles relating to it have been properly grasped, but those who are unfamiliar with the subject are apt to underrate the difficulty of correctly practising it.

Simple Tables.—The first thing to be done in the construction a table is to form a clear idea of what the table is to show, and to express that idea in accurate language. This is a matter which is often neglected, and it is a source of much waste of time and occasionally of misapprehension to those who have to study the figures thus presented. No table ought to be considered complete without a "heading" accurately describing its contents, and it is frequently necessary that such headings should be rather long. It has been said that "you can prove anything by statistics." This statement is of course absurd, taken absolutely, but, like most assertions which are widely believed, it has a grain of truth in it. If this popular saying ran "you can prove anything by tables with slovenly and ambiguous headings," it might be assented to without hesitation. The false "statistical" facts which obtain a hold of the public mind may often be traced to some widely circulated table, to which either from stupidity or carelessness an erroneous or inaccurate "heading" has been affixed.

A statistical table in its simplest form consists of "primaries" representing phenomena of the same class, but existing at different points of time, or coming into existence during different portions of time. This is all that is essential to a table, though other things are usually added to it as an aid to its comprehension. A table stating the number of persons residing in each county of England on a given day of a given year, and also, in another column, the corresponding numbers for the same counties on the corresponding day of the tenth year subsequently, would be a simple tabular statement of the general facts regarding the total population of those counties supplied by two successive censuses. Various figures might, however, be added to it which would greatly add to its clearness. There might be columns showing the increase or decrease for each county and for the whole kingdom during the ten years, and another column showing what *proportion*, expressed in percentages, these increases or decreases bore to the figures for the earlier of the two years. Then there might be two columns showing what proportions, also expressed as percentages, the figures for each county bore in each year to the figures for the whole kingdom. The nine-column table thus resulting would still be simple, all the figures being merely explicit assertions of facts which are contained implicitly in the original "primaries."

Complex Tables.—Suppose now we have another table precisely similar in form to the first, and also relating to the counties of England, but giving the number of houses existing in each of them at the same two dates. A combination of the two would form a complex table, and an application of the processes of arithmetic would make evident a number of fresh facts, all of which would be implied in the table, but would not be obvious to most people until explicitly stated.

The technical work of the statistician consists largely in operations of which the processes just referred to are types.

Proportions.—The most usual and the best mode of expressing the proportion borne by one statistical quantity to another is to state it as a percentage. In some cases another method is adopted—namely, that of stating the proportion in the form "one in so many." This method is generally a bad one, and its use should be discouraged as much as possible, the chief reason being that the changing portion of this kind of proportional figure becomes greater or less inversely, and not directly, as the phenomenon it represents increases or diminishes.

Averages.—Averages or means are for statistical purposes divided into two classes, the *geometrical* and *arithmetical*. An arithmetical mean is the sum of all the members forming the series of figures under consideration divided by their number, without reference to their *weight* or relative importance among themselves. A geometrical mean is the sum of such figures divided by their number, with due allowance made for their weight. An example will make this clear, and the simplest example is taken from a class of statistical quantities of a peculiar kind—namely, *prices*. The price of a given article is the approximate mathematical expression of the rates, in terms of money, at which exchanges of the article for money were actually made at or about a given hour on a given day. A *quotation of price* such as appears in a daily price list is, if there has been much fluctuation, only a very rough guide to the actual rates of exchange that have been the basis of the successive bargains making up the day's business. But let us suppose that the closing price each day may be accepted as a fair representative of the day's transactions, and let us further suppose that we desire to obtain the *average* price for thirty days. Now the sum of the prices in question divided by thirty would be the arithmetical mean, and its weak point would be that it made no allowance for the fact that the business done on some days is much larger than that done on others, in other words, it treats them as being all of equal weight. Now if, as is actually the case in some markets, we have a daily account of the *total quantities sold* we can weight the members accurately, and can then obtain their geometrical mean. There are cases in which the careless use of arithmetical means misleads the student of the social organism seriously. It is often comparatively easy to obtain arithmetical means, but difficult to obtain geometrical means. Inferences based on the former class of average should be subjected to the most rigid investigation.

Before closing this short survey of the very important subject of averages or means, it is needful to discuss briefly the nature of the phenomena which they may safely be regarded as indicating, when they have been properly obtained. Given a geometric mean of a series of numbers referring to no matter what phenomenon, it is obvious that the value of the mean as a *type* of the whole series will depend entirely on the extent of divergence from it of the members of the series as a body. If we are told that there are in a certain district 1000 men, and that their average height is 5 feet 8 inches, and are told nothing further about them, we can make various hypotheses as to the structure of this body from the point of view of height. It is possible that they may consist of a rather large number of men about 6 feet high, and a great many about 5 feet 5 inches. Or the proportions of relatively tall and short men may be reversed, that is, there may be a rather large number of men about 5 feet 4 inches, and a moderate number of men about 5 feet 11 inches. It is also possible that there may be very few men whose height is exactly 5 feet 8 inches, and that the bulk of the whole body consists of two large groups—one of giants and the other of dwarfs. Lastly, it is possible that 5 feet 8 inches may really give a fair idea of the height of the majority of the men, which it would do if (say) 660 of them were within an inch of that height, either by excess or deficiency, while of the remainder one half were all above 5 feet 9 inches and the other half all below 5 feet 7 inches. This latter supposition would most likely be found to be approximately correct if the men belonged to a race whose average height was 5 feet 8

inches, and if they had been collected by chance. The extent of the divergence of the items composing an average from the average itself may be accurately measured and expressed in percentages of the average, the algebraic signs + and − being employed to indicate the direction of the variation from the mean. An average may, therefore, advantageously be supplemented—(1) by a figure showing what proportion of the members from which it is derived differ from the average by a relatively small quantity, and (2) by figures showing the maximum and minimum deviations from the average. The meaning of the term "relatively small" must be considered independently in each investigation. Further remarks on averages will be found in the works mentioned at the conclusion of this article.

Prices.—Reference has already been made to the peculiar class of statistical quantities known as *prices*. Prices in their widest sense include all figures expressing *ratios of exchange*. In modern society the terms of exchange are always expressed in money, and the things for which money is exchanged are—(1) concrete entities with physical attributes, such as iron or wheat, (2) immediate rights, such as those given by interest-bearing securities of all kinds, by bills of exchange, by railway or steamship contracts to carry either passengers or goods, and by bargains relative to the foreign exchanges, (3) contingent rights, such as those implied in policies of insurance. All these rates of exchange belong to the same category, whether they are fixed within certain limits by law, as in the case of railway charges, or are left to be determined by the "higgling of the market." All these cases of price may conceivably come within the operation of the statistical method, but the only matter connected with price which it is necessary to refer to here is the theory of the *index number*.

Index Numbers.—The need for these became conspicuous during the investigations of Tooke, Newmarch, and others into the general cyclical movements of the prices of commodities, and to construct a good system of these may be said to be one of the highest technical aims of the statistical method. In comparing the prices of different years it was soon observed that, though whole groups of articles moved upwards or downwards simultaneously, they did not all move in the same proportion, and that there were nearly always cases in which isolated articles or groups of articles moved in the opposite direction to the majority of articles. The problem presented to statisticians therefore was and is to devise a statistical expression of the general movement of prices, in which all prices should be adequately represented. The first rough approximation to the desired result was attained by setting down the percentages representing the movements, with their proper algebraic signs before them, and adding them together algebraically. The total with its proper sign was then divided by the number of articles, and the quotient represented the movement in the prices of the whole body of articles during the period under consideration. It was soon seen, however, that this procedure was fatally defective, inasmuch as it treated all prices as of equal weight. Cotton weighed no more than pimento, and iron no more than umbrellas. Accordingly an improvement was made in the procedure, first by giving the prices of several different articles into which cotton, iron, and other important commodities entered, and only one price each in the case of the minor articles, and secondly by fixing on the price of some one article representing iron or cotton, and multiplying it by some number selected with the view of assigning to these articles their proper weights relatively to each other and to the rest. The objection to both these plans is the same,—that the numbers attached to the various articles or groups of articles are purely arbitrary, and of late years attempts have been made to obtain what may be called *natural* index numbers, the most successful so far being that of Mr Robert Giffen, whose index numbers are obtained from the declared values of the imports or exports into or from the United Kingdom of the articles whose prices are dealt with. In the case of both imports and exports Mr Giffen worked out the proportion borne by the value of each article to the total value for a series of years. Deducting the "unenumerated" articles, a series of numbers was thus obtained which could be used as the means of weighting the prices of the articles in an investigation of a movement of prices. This procedure is no doubt susceptible of further improvement, like its predecessors, but it is a great advance on the arbitrary systems of index numbers employed in them.

The Desirability of Increased Uniformity in Statistics.—One of the most serious difficulties in connexion with statistical investigations is the variety of the modes in which primaries of the same order are obtained, as regards dates and periods. This is a matter of which all persons who have occasion to use statistics are made painfully aware from time to time. Some attempts have lately been made to introduce more harmony into the official statistics of the United Kingdom, and some years ago a committee of the Treasury sat to inquire into the matter. The committee received a good deal of evidence, and presented a report, from which, however, certain members of the committee dissented, preferring to express their views separately. The evidence will be found very interesting by all who wish to obtain an insight into the genesis of the official statistics of the country. The report and evidence were published in the June number of the *Journal of the Statistical Society* for 1881, as well as in the usual official form.

The International Institute of Statistics.—The absence of uniformity in statistics which is felt in England is not so marked in foreign countries, where the principle of centralization in arrangements of a political character is more powerful than it is here. In several Continental countries and in the United States there are statistical bureaus with definite duties to perform. In the United Kingdom, as already remarked, the nearest approach to a central statistical office is the Commercial and Statistical Department of the Board of Trade, on which the work of furnishing such statistics as are not definitely recognized as within the province of some other state department usually falls. Various attempts have been made to introduce more uniformity into the statistics of all countries. It was with this object that statistical congresses have met from time to time since 1853. An endeavour was made at the congress held in 1876 at Budapest to arrange for the publication of a system of international statistics, each statistical bureau undertaking a special branch of the subject. The experiment was, however, foredoomed to be only a very partial success, first because all countries were not then and are not yet furnished with central statistical offices, and secondly because the work which fell on the offices in existence could only be performed slowly, as the ordinary business of the offices necessarily left them little leisure for extra work. In 1885, at the jubilee of the London Statistical Society, a number of eminent statistical officials from all parts of the world except Germany were present, and the opportunity was taken to organize an International Institute of Statistics with a view to remedying the defects already ascertained to exist in the arrangements made by the congresses. The only obstacle to securing a proper representation of all countries was the absence of any German delegates, none of the official heads of the German statistical office being allowed to attend,—apparently on political grounds. Since then assurances of a satisfactory kind have been given to the German Government that their servants would be in no way committed to any course disapproved by that Government if they gave their assistance to the institute, from the formation of which it is hoped that much advantage may result. For information as to the constitution and objects of the institute reference may be made to a paper by Dr F. X. von Neumann-Spallart in vol. i. (1886) of the *Bulletin de l'Institut International de Statistique* (Rome, 1886).

Handbuch der Statistik*, 2d ed., Vienna, 1882; K. Knies, *Die Statistik als selbständige Wissenschaft*, Cassel, 1850; Georg Mayr, *Die Gesetzmässigkeit im Gesellschaftsleben*, Munich, 1877 (abridged translation in *Journ. Stat. Soc.*, Sept. 1883; the work has also been translated into Italian with valuable notes by G. B. Salvioni, Turin, 1886); Adolphe Quetelet, various works, but especially that entitled *Sur l'Homme et le Développement de ses Facultés, ou Essai de Physique Sociale*, 2 vols., Paris, 1835, and *Letters on the Theory of Probabilities*, already referred to; Albert C. F. Schäffle, *Bau und Leben des socialen Körpers*, Tübingen, 1881; Herbert Spencer, *Principles of Sociology*, especially part ii. pp. 465 *sq.*; Adolf Wagner, article "Statistik" in Bluntschli-Brater's *Staatswörterbuch*, vol. x. (W. H. O.)

STATIUS, PUBLIUS PAPINIUS, Roman poet, lived from about 45 to 96 A.D., so far as can be judged from indications afforded by his poems. He was, to a great extent, born and trained to the profession of a poet. The Statii were of Græco-Campanian origin, and were gentle, though impoverished, and the family records were not without political distinctions. The elder Statius, our poet's father, was the Orbilius of his time, and taught with distinguished success at Naples and Rome. From boyhood to age he proved himself a champion in the poetic tournaments which formed an important part of the amusements of the early empire. The younger Statius declares that his father was in his time equal to any literary task, whether in prose or verse. Probably our poet inherited a modest competence and was not under the necessity of begging his bread from wealthy patrons. So far as appears he never pursued any occupation but that of poet, as poor an occupation in those days as in ours, if we may believe Juvenal and Martial. Statius certainly wrote poems to order (as *Silvae*, i. 1, 2, ii. 7, and iii. 4), but there is no indication that the material return for them was important to him. In his seventh satire Juvenal speaks of the immense public enthusiasm which attended the recitation of the *Thebais*, when the benches "were breaking" with applause; but the poet, he says, might have starved had not Paris, the favourite comedian of the day, bought from him the libretto of a comic opera. This reference

of Juvenal deserves, however, as little to be accepted literally as his misleading allusions to Quintilian in the same satire. Of events in the life of Statius we know little. He married early a young widow, for whom he expresses tender affection in some of the few obviously sincere verses he ever wrote. From his boyhood he was victorious in poetic contests,—many times at his native city Naples, thrice at Alba, where he received the golden crown from the hand of the emperor. But at the great Capitoline competition (probably on its third celebration in 94 A.D.) Statius failed to win the coveted chaplet of oak leaves. No doubt the extraordinary popularity of his *Thebais* had led him to regard himself as the supreme poet of the age, and when he could not sustain this reputation in the face of rivals from all parts of the empire he accepted the judges' verdict as a sign that his day was past, and retired to Naples, the home of his ancestors and of his own young days. We still possess the poem he addressed to his wife on this occasion (*Silv.*, iii. 5). It was a hard task to overcome her objections to turning her back upon the great capital. Chief among them was that which arose from a fear lest it should prove difficult to find in Naples a husband for her daughter (by her first marriage; she had no children by Statius). There are hints in this poem which naturally lead to the surmise that Statius was suffering from a loss of the emperor's favour; he may have felt that a word from Domitian would have won for him the envied garland, and that the word ought to have been given. In the preface to book iv. of the *Silvae* there is mention of detractors who hated our poet's style, and these may have succeeded in inducing a new fashion in poetry at court. Such an eclipse, if it happened, must have cut Statius to the heart. He appears to have relished thoroughly the rôle of court-poet. The statement sometimes made that the elder Statius had been the emperor's teacher, and had bestowed many favours on him, so that the son inherited a debt of gratitude, seems to have no solid foundation. Statius lauds the emperor, not to discharge a debt, but rather to create an obligation. His flattery is as far removed from the gentle propitiatory tone of Quintilian as it is from the coarse and crawling humiliation of Martial. It is in the large extravagant style of a nature in itself healthy and generous, which has accepted the theme and left scruples behind. In one of his prefatory epistles Statius declares that he never allowed any work of his to go forth without invoking the godhead of the divine emperor. The poem on the equestrian statue of Domitian set up on the Capitol (*Silv.*, i. 1) is such colossal rodomontade that if the emperor had had a grain of humour in his composition he must have died of merriment on receiving it. Statius had taken the full measure of Domitian's gross taste, and carefully puts conscience and sincerity out of view, lest some uneasy twinge should mar his master's enjoyment. But in one poem, that in which the poet pays his due for an invitation to the imperial table, we have sincerity enough. Statius clearly feels all the raptures he expresses. He longs for the power of him who told the tale of Dido's banquet, and for the voice of him who sang the feast of Alcinous, that he may give forth utterance worthy of the lofty theme. The poet seemed, he says, to dine with great Jove himself and to receive nectar from Ganymede the cup-bearer (an odious reference to the imperial favourite Earinus). All his life hitherto has been barren and profitless. Now only has he begun to live in truth. "O ruler over all the lands, and mighty father of the world which thou hast conquered, do I, *recumbent*, see thee, thou hope of all mankind, and nursling of all the gods? Is it mine to gaze from near at hand on thy features, with the wine-cup and the feast beside me, *while I am forbidden to rise*?" The palace struck on the poet's fancy like the very hall of heaven; nay, Jove himself marvels at its beauty, but is glad that the emperor should possess such an earthly habitation; he will thus feel less desire to seek his destined abode among the immortals in the skies. Yet even so gorgeous a palace is all too mean for his greatness and too small for his vast presence. "But it is himself, himself, that my eager eye has alone time to scan. He is like a resting Mars or Bacchus or Alcides." Martial too swore that, were Jove and Domitian both to invite him to dinner for the same day, he would prefer to dine with the greater potentate on the earth. Pliny, however, has sketched for us the state dinners of Domitian, where the coarse contempt of the tyrant overclouded the guests, and where a man who still respected himself had torments to endure. Martial and Statius were no doubt supreme among the imperial flatterers. Each was the other's only serious rival. It is therefore not surprising that neither should breathe the other's name. Even if we could by any stretch excuse the bearing of Statius towards Domitian, he could never be forgiven the poem entitled "The Hair of Flavius Earinus," Domitian's Ganymede (*Silv.*, iii. 4), a poem than which it would be hard to find a more repulsive example of real poetical talent defiled for personal ends. Well for Statius that he did not, like Martial, live on into the days of Nerva to write sorry palinodes! Everything points to the conclusion that he did not survive his emperor—that he died, in fact, a short time after leaving Rome to settle in Naples. Apart from the emperor and his minions, the friendships of Statius with men of high station seem to have been maintained on fairly equal terms. He was clearly the poet of society in his day as well as the poet of the court.

As poet, Statius unquestionably shines in many respects when compared with the other post-Augustans. He was born with exceptional talent, and his poetic expression is, with all its faults, richer on the whole and less forced, more buoyant and more felicitous, than is to be found elsewhere in the Silver Age of Latin poetry. Statius is at his best in his occasional verses, the "*Silvae*," which have a character of their own, and in their best parts a charm of their own. The title was proper to verses of rapid workmanship, on everyday themes. Statius prided himself on his powers of improvisation, and he seems to have been quite equal to the Horatian feat of dictating two hundred lines in an hour, while standing on one leg. The improvisatore was in high honour among the later Greeks, as Cicero's speech for the poet Archias indicates; and the poetic contests common in the early empire did much to stimulate ability of the kind. Statius speaks of his "*Silvae*" (preface to book i.) as having "streamed from him under the influence of sudden inspiration, and with a certain pleasure due to their rapidity." No one poem occupied more than two days; some came to birth at the dinner table, many while the poet's friend Pollius sat by his side, and shuddered at the audacity of his pen (preface to book iii.). It is to this velocity that the poems owe their comparative freshness and freedom, along with their loose texture and their inequality. There are thirty-two poems, divided into five books, each with a dedicatory epistle. Of nearly four thousand lines which the books contain, more than five-sixths are hexameters. Four of the pieces (containing about 450 lines) are written in the hendecasyllabic metre, the "tiny metre of Catullus," and there is one Alcaic and one Sapphic ode. But the poems in these metres are merely the experiments of a poet who knows well that his strength lies in the hexameter, which in his hands shows greater freedom, variety, and music than it exhibits when handled by other poets of the Silver Latin Age. The subjects of the "*Silvae*" are very various. Five poems are devoted to flattery of the emperor and his favourites; but of these enough has already been said. Six are lamentations for deaths, or consolations to survivors. Statius seems to have felt a special pride in this class of his productions; and certainly, notwithstanding the excessive and conventional employment of pretty mythological pictures, with other affectations, he sounds notes of pathos such as only come from the true poet. There are oftentimes traits of an almost modern domesticity in these verses, and Statius, the childless, has here and there touched on the charm of childhood in lines for a parallel to which, among the ancients, we must go, strange to say, to his rival Martial. One of the *epicedia*, that on Priscilla the wife of Abascantus, Domitian's freedman (*Silv.*, v. 1), is full of interest for the picture it presents of the official activity of a high

officer of state. Another group of the "*Silvae*" give picturesque descriptions of the villas and gardens of the poet's friends. In these we have a more vivid representation than elsewhere of the surroundings amid which the grandees of the early empire lived when they took up their abode in the country. It was of these pieces that Niebuhr thought when he said that the poems of Statius are charming to read in Italy. They exhibit, better even than Pliny's well-known letters, the passion of the rich Roman for so constructing his country house that light, air, sun, and leafage should subserve his luxury to the utmost, while scope was left for displaying all the resources of art which his wealth enabled him to command. As to the rest of the "*Silvae*," the congratulatory addresses to friends are graceful but commonplace, nor do the jocose pieces call for special mention here. In the "Kalendae Decembres" we have a striking description of the gifts and amusements provided by the emperor for the Roman population on the occasion of the Saturnalia. In his attempt at an epithalamium (*Silv.*, i. 2) Statius is forced and unhappy. But the birthday ode in Lucan's honour (*Silv.*, ii. 7) has, along with the accustomed exaggeration, many powerful lines, and shows high appreciation of preceding Latin poets. Some phrases, such as "the untaught muse of high souled Ennius" and "the lofty passion of sage Lucretius," are familiar words with all scholars. The ode ends with a great picture of Lucan's spirit rising after death on wings of fame to regions whither only powerful souls can ascend, scornfully surveying earth and smiling at the tomb, or reclining in Elysium and singing a noble strain to the Pompeys and the Catos and all the "Pharsalian host," or with proud tread exploring Tartarus and listening to the wailings of the guilty, and gazing at Nero, pale with agony as his mother's avenging torch glitters before his eyes. It is singular to observe how thoroughly Nero had been struck out of the imperial succession as recognized at court, so that the "bald Nero" took no umbrage when his flatterer-in-chief profanely dealt with his predecessor's name.

The epic poems of Statius are less interesting because cast in a commoner mould, but they deserve study in many respects. They are the product of long elaboration. The "*Thebais*," which the poet says took twelve years to compose, is in twelve books, and has for its theme the old "tale of Thebes"—the deadly strife of the Theban brothers. There is also preserved a fragment of an "*Achilleis*," consisting of one book and part of another. In the weary length of these epics there are many flowers of pathos and many little finished gem-pictures, but the trammels of tradition, the fashionable taste, and the narrow bars of education check continually the poet's flight. The public idea of what an epic poem should be was firmly fixed, and Statius would not have towered above the thousand poets of his day in the estimation of his countrymen had he not given full embodiment to the idea. Not merely were the materials for his epics prescribed to him by rigid custom, but also to a great extent the method by which they were to be treated. All he could do was to sound the old notes with a distinctive *timbre* of his own. The gods must needs wage their wonted epic strife, and the men, their puppets, must dance at their nod; there must needs be heavenly messengers, portents, dreams, miracles, single combats, similes, Homeric and Virgilian echoes, and all the other paraphernalia of the conventional epic. But Statius treats his subjects with a boldness and freedom which contrast pleasingly with the timid traditionalism of Silius Italicus and the stiff scholasticism of Valerius Flaccus. The vocabulary of Statius is conspicuously rich, and he shows audacity, often successful, in the use of words and metaphors. At the same time he carried certain literary tricks to an aggravating pitch, in particular the excessive use of alliteration, and the misuse of mythological allusion. The most well-known persons and places are described by epithets or periphrases derived from some very remote connexion with mythology, so that many passages are as dark as Heraclitus. The *Thebais* is badly constructed. The action of the epic is hindered and stopped by enormous episodes, one of which fills one sixth of the poem. Nor had Statius a firm grasp or clear imagination of character. So trying are the late ancient epics to a modern reader that he who has read any one of the three—Statius, Silius, and Valerius (Lucan stands apart)—will with difficulty be persuaded to enter on the other two. Yet, if he honestly reads them all, he can hardly fail to rank Statius the highest of the three by a whole sphere.

The *editio princeps* of the epics is dated 1470, of the *Silvae* 1472. Notable editions since have been those of Bernartius (Antwerp, 1595), Gronovius (1653), and Barth (1664). The best text is the Teubner (the *Achilleis* and *Thebais* by Kohlmann, the *Silvae* by Baehrens). Among editions of portions of Statius's works, that of the *Silvae* by Jeremiah Markland, fellow of Peterhouse in Cambridge (1728), deserves special attention. The brilliance and erudition of the work mark him out as one of the best Latin scholars who ever lived. A critical edition of the *Thebais* and *Achilleis* was begun by O. Müller (1870) but not completed. The condition of the text of the *Silvae* is one of the most curious facts in the history of ancient literature. Poggio discovered a MS at St Gall and brought it into Italy. This MS has disappeared, but from it are derived all our existing MSS, except one of the birthday ode to Lucan, now at Florence, and of the 10th century. Politian collated Poggio's MS with the *editio princeps*, and the collation has come down to us, and is the principal basis of the text. The MSS. of the epics are numerous, as was to be expected from their great popularity in the Middle Ages, to which Dante is witness (see *Purg.*, xxi., where an interview with the shade of Statius is described at some length). (J. S. R.)

STATUTE, or Act of Parliament, is a law made by the sovereign power in the state, that is, the king, by and with the advice and consent of the lords spiritual and temporal and commons in parliament assembled. It forms a part of the *lex scripta*, or written law, which by English legal authorities is used solely for statutory law, a sense much narrower than it bore in Roman law. To make a statute the concurrence of the crown and the three estates of the realm is necessary. Thus a so-called statute of 5 Ric. II. c. 5, directed against the Lollards, was afterwards repudiated by the Commons as passed without their assent. The validity of a statute was indeed at times claimed for ordinances such as that just mentioned, not framed in accordance with constitutional rule, and was actually given to royal proclamations by 31 Hen. VIII. c. 8. But this Act was repealed by 1 Edw. VI. c. 12, and since that time nothing but a statute has possessed the force of a statute, unless indeed certain rules or orders depending ultimately for their sanction upon a statute may be said to have such force. Examples of what may be called indirect legislation of this kind are orders in council (see PRIVY COUNCIL), by-laws made under the powers of the Public Health Act, and rules of court such as those made under the powers of the Judicature Acts and Acts of Sederunt of the Court of Session.

The history of statutory legislation and the modern procedure by which bills become statutes are sufficiently treated under ACT OF PARLIAMENT and PARLIAMENT. It is proposed in this place to deal with the legal rather than the political aspect of the subject, and to give a short list of some of the more important statutes which have been passed by the legislature.

The list of statutes as at present existing begins with the Statute of Merton, 1235.[1] Many of the earlier statutes are known by the names of the places at which they were passed, *e.g.*, the Statutes of Merton, Marlbridge, Gloucester, Westminster, or by their initial words, *e.g.*, *Quia Emptores*, *Circumspecte agatis*. The earliest existing statute roll is 6 Edw. I. (the Statute of Gloucester). After 4 Hen. VII. the statute roll ceased to be made up, and enrolments in Chancery (first made in 1485) take its place. Some of the Acts prior to the Statute of Gloucester are of questionable authority, but have gained recognition by a kind of prescription.

All statutes were originally public, irrespectively of their subject matter. The division into public and private dates from the reign of Richard III. At present statutes are of four kinds—public general Acts, public local and personal Acts, private Acts printed by the queen's printers, and private Acts not so printed. The division into public general and public local and personal rests upon a resolution of both Houses of Parliament in 1798. In 1815 a resolution was passed in accordance with which private Acts are printed, with the exception of name, estate, naturalization, and divorce Acts. The last two are now practically superseded by the provisions of the Divorce Act, 1857, and the Naturalization Act, 1870. Since 1815 it has been usual to refer to public general Acts by Arabic numerals, *e.g.*, 5 and 6 Vict. c. 21, public local and personal Acts by small Roman numerals, *e.g.*, 5 and 6 Vict. c. xxi. Each Act is strictly but a chapter of the legislation of the session, which is regarded as composing a single Act divided into chapters for convenience, the chapters themselves being also called Acts. The citation of previous Acts is provided for by 13 and 14 Vict. c. 21, § 3. It is now usual for each chapter or Act to contain

[1] Ruffhead's edition of the statutes begins with the Magna Carta of 1225. But in the *Revised Statutes* that form of Magna Carta which is now law appears as a statute of the year 1297. It is often known as *Confirmatio Cartarum*, and is a recital and confirmation by Edward I. of the chief provisions of John's charter.

a short title by which it may be cited, *e g*, the Elementary Education Act, 1870 Sometimes a series of Acts is grouped under a generic title, *e g*, the Merchant Shipping Acts, 1854 to 1883 [1] 8 and 9 Vict c 113, § 3, makes evidence the queen's printers' copies of private and local and personal Acts A private Act not printed by the queen's printers is proved by an examined copy of the parliament roll A public Act binds all subjects of the realm, and need not be pleaded (except where the law from motives of policy specially provides for pleading certain Acts, as in the defences of not guilty by statute, the Statute of Frauds, and the Statute of Limitations) A private Act must generally be pleaded, and does not as a rule bind strangers to its provisions Formerly an Act took effect from the first day of the session in which it was passed The hardship caused by this technical rule has been obviated by 33 Geo III c 13, by which an Act takes effect from the day on which it receives the royal assent, where no other date is named This has been held to mean the beginning of the day, so as to govern all matters occurring on that day An Act cannot in the strict theory of English law become obsolete by disuse Nothing short of repeal can limit its operation The law has, however, been interpreted in some recent cases with somewhat less rigour In the case of a prosecution for blasphemy in 1883 (Reg *v* Ramsay) Lord Coleridge said, "though the principles of law remain unchanged, yet (and it is one of the advantages of the common law) their application is to be changed with the changing circumstances of the times "[2] This would be applicable as much to the interpretation of statutes as to other parts of the common law The title, preamble, and marginal notes are strictly no part of a statute, though they may at times aid in its interpretation

Besides the fourfold division above mentioned, statutes are often classed according to their subject-matter, as perpetual and temporary, penal and beneficial, imperative and directory, enabling and disabling Temporary Acts are those which expire at a date fixed in the Act itself Thus the Army Act is passed annually and continues for a year, the Ballot Act, 1872, expired at the end of 1880, and the Regulation of Railways Act, 1873, at the end of five years By means of these temporary Acts experimental legislation is rendered possible in many cases where the success of a new departure in legislation is doubtful In every session an Expiring Laws Continuance Act is passed for the purpose of continuing (generally for a year) a considerable number of these temporary Acts By 48 Geo III c 106 a continuing Act is to take effect from the date of the expiration of a temporary Act, where a bill for continuing the temporary Act is in parliament, even though it be not actually passed before the date of the expiration

Penal Acts are those which impose a new disability, beneficial those which confer a new favour An imperative statute (often negative or prohibitory in its terms) makes a certain act or omission absolutely necessary, and subjects a contravention of its provisions to a penalty A directory statute (generally affirmative in its terms) recommends a certain act or omission, but imposes no penalty on non observance of its provisions To determine whether an Act is imperative or directory the Act itself must be looked at, and many nice questions have arisen on the application of the rule of law to a particular case

Enabling statutes are those which enlarge the common law, while disabling statutes restrict it This division is to some extent coincident with that into beneficial and penal Declaratory statutes, or those simply in affirmance of the common law, were at one period not uncommon, but they are now practically unknown The Statute of Treasons of Edward III is an example of such a statute Statutes are sometimes passed in order to overrule specific decisions of the courts Examples are the Factors Act, 1877, the Territorial Waters Jurisdiction Act, 1878, the Sale of Food and Drugs Act, 1879

The construction or interpretation of statutes depends partly on the common law, partly on statute The main rules of the common law, as gathered from the best authorities, are these (1) Statutes are to be construed, not according to their mere letter, but according to the intent and object with which they were made (2) The relation of the statute to the common law is to be considered In the words of the resolution of the Court of Exchequer in Heydon's Case, 3 *Coke's Rep*, 7, the points for consideration are—"1, What was the common law before the making of the Act? 2, What was the mischief and defect against which the common law did not provide? 3, What remedy the parliament hath resolved and appointed to cure the disease of the Commonwealth? 4, The true reason of the remedy" (3) Beneficial or remedial statutes are to be liberally, penal more strictly, construed (4) Other statutes *in pari materia* are to be taken into consideration (5) A statute which treats of persons of inferior rank cannot by general words be extended to those of superior rank (6) A statute does not bind the crown, unless it be named therein (7) Where the provision of a statute is general, everything necessary to make such provision effectual is implied. (8) A later statute repeals an earlier, as far as the two are repugnant, but, if they may stand together, repeal will not be presumed (9) There is a presumption against creation of new or ousting of existing jurisdictions, against impairing obligations, against retrospective effect, against violation of international law, against monopolies, and in general against what is inconvenient or unreasonable (10) If a statute inflicts a penalty, the penalty implies a prohibition of the act or omission for which the penalty is imposed Whether the remedy given by statute is the only one depends on the words of the particular Act In some cases an action or an indictment will lie, in others the statutory remedy, generally summary, takes the place of the common law remedy. In some few instances the courts have construed the imposition of a penalty as operating not to invalidate a contract but to create a tax upon non-compliance with the terms of the statute What may be called the statutory rules of construction provide, *inter alia*, that any Act referring to England includes Wales and Berwick-upon-Tweed (20 Geo II c 42), and that all words importing the masculine gender shall be taken to include females, and the singular to include the plural and the plural the singular (13 & 14 Vict c 21, § 4) The same Act further provides that, where any Act repealing in whole or in part any former Act is itself repealed, such last repeal shall not revive the Act or provisions before repealed unless words be added to that effect (§ 5), and that, wherever any Act shall be made repealing in whole or in part any former Act and substituting some provision or provisions instead of the provision or provisions repealed, such provision or pro-

[1] A short title has been occasionally given by retrospection to an Act which did not originally possess it For instance, the Conveyancing Act, 1881, enacts that the Act of 5 and 6 Will IV c 62, the original title of which is of unwieldy length, may be cited for the future as the Statutory Declarations Act, 1835 In some cases the title has been changed Thus the name of the Summary Procedure (Scotland) Act, 1864, was changed in 1881 to that of the Summary Jurisdiction Act, 1864

[2] This opinion carries out to a certain extent the view of Locke, who in Article 79 of his Carolina Code recommended the determination of Acts of the legislature by effluxion of time after a hundred years from their enactment

visions so repealed shall remain in force until the substituted provision or provisions shall come into operation by force of the last Act (§ 6). Numerous interpretations of particular words are contained in Acts of Parliament, either general, as "month," "county," "land," and other words in 13 and 14 Vict. c. 21, § 4, or for the purposes of the Act, as "settlement" for the purposes of the Settled Land Act, 1882.

The earlier Acts are generally simple in character and language, and comparatively few in number. At present the number passed every session is enormous; in the session of 1885 it was 80 general and 190 local and personal Acts. Without going as far as to concede with an eminent legal authority that of such legislation three-fourths is unnecessary and the other fourth mischievous, it may be admitted that the immense library of the statutes would be but a trackless desert without trustworthy guides. Revision of the statutes was evidently regarded by the legislature as desirable as early as 1563 (see the preamble to 5 Eliz. c. 4). It was demanded by a petition of the Commons in 1610. Both Coke and Bacon were employed for some time on a commission for revision. At times Consolidation Acts in the nature of digests of law (generally amending as well as consolidating) were passed, such as the Merchant Shipping Act, 1854, and the Criminal Law Consolidation Acts of 1861. The most important action, however, was the nomination of a revision committee by Lord Chancellor Cairns in 1868, the practical result of which has been the issue of an edition of the *Revised Statutes* in eighteen volumes, bringing the revision of statute law down to 1878. This edition is of course subject to the disadvantage that it becomes less accurate every year as new legislation appears. An index to the statutes which are still law is published about every three years by the Council of Law Reporting.

The principal statutes may be classified under various heads according to the matter with which they deal. It should be remembered at the same time that many of them—Magna Carta, for example—might fall with equal correctness under more than one head. A division, convenient, if not exhaustive, would be into historical, constitutional, legal, and social.

Historical.—Under this head would come those Acts which to a greater or less extent mark important epochs in the national history, such as the Statute of Rhuddlan, the Acts of Union defining the relations of Wales, Scotland, and Ireland to England, the Act of Settlement, the Stamp Act of 1765—the proximate cause of the revolt of the American colonies,—the Acts abolishing the slave trade and the corn laws, and those defining the position of dependencies, such as the Act for the Better Government of India, 1858, and the British North America Act, 1867.

Constitutional.—The principal Acts of this class would be Magna Carta, the statutes *De Tallagio non Concedendo* and *De Prærogativa Regis* and those dealing with mortmain and treason, the Petition of Right, the Bill of Rights, the Septennial Act, the Royal Marriage Act, the Mutiny, Militia, Naval Discipline, and Foreign Enlistment Acts, and the Acts affecting the parliamentary franchise from the time of Henry VI to the Redistribution of Seats Act, 1885. Under this head too might be placed the numerous Acts dealing with the question of religion. Some of the more interesting of these are the *Articuli Cleri*, the Statutes of Provisors, the Acts of Henry VIII. abolishing monasteries, the Acts of Supremacy and Uniformity of Henry VIII., Elizabeth, and Charles II., the Toleration, Catholic Emancipation, Tithe Commutation, Church Discipline, Public Worship Regulation, Irish Church, and Scottish Patronage Abolition Acts.

Legal.—The most important of this class are perhaps the Statutes of *Quia Emptores* and *De Donis*, the Statutes of Uses and of Wills, the Statutes of Limitation, the Statute of Frauds and its amendments, the Fines and Recoveries Act, the Conveyancing, Settled Land and Settled Estates, and Married Women's Property Acts, and the Acts for the amendment of procedure, *e.g.*, the Chancery Amendment, Common Law Procedure, Judicature, and Appellate Jurisdiction Acts.

Social.—Social legislation (other than mere sumptuary laws) is of comparatively modern introduction. Among earlier instances are the Statute of Labourers of Edward III and the Poor Law of Elizabeth. More modern examples are the Factory, Public Health, and Artisans' Dwellings Act, and, perhaps greatest of all, the Education Acts. Besides these there are the Acts dealing with patent, copyright, summary jurisdiction, friendly and building societies, trades unions, savings banks, theatres, commons preservation, and agricultural holdings. Acts which have trade for their special object are the Bank Charter, Merchant Shipping, Bills of Lading, Bills of Exchange, Crossed Cheques, Factors, Stamp, Licensing, Bankruptcy, and Trade Marks Acts.

The chief editions of the statutes are the *Statutes of the Realm* printed by the queen's printers, Ruffhead's, and the fine edition issued from 1810 to 1824 in pursuance of an address from the House of Commons to George III. The safest authority is of course the *Revised Statutes*. Chitty's collection of statutes of practical utility is a useful compilation. Among the earlier works on statute law may be mentioned the readings on statutes by great lawyers, such as the second volume of Coke's *Institutes*, Bacon's *Reading on the Statute of Uses*, Barrington's *Observations on the more Ancient Statutes from Magna Carta to the 21 Jac. I. c. 27* (5th ed. 1796), and the Introduction to Blackstone's *Commentaries*. Among the later works are the treatises of Dwarris (2d ed. 1848) and Sir P. B. Maxwell (2d ed. 1883) on the interpretation of statutes, and Sir H. Thring's *Practical Legislation, or the Composition and Language of Acts of Parliament*.

Scotland.—The statutes of the Scottish parliament before the Union differed from the English statutes in two important respects,—they were passed by the estates of the kingdom sitting together and not in separate Houses, and from 1367 to 1690 they were discussed only after preliminary consideration by the Lords of Articles. An Act of the Scottish parliament may in certain cases cease to be binding by desuetude. "To bring an Act of Parliament like those we are dealing with" (*i.e.*, the Sabbath Profanation Acts) "into what is called in Scotch law the condition of desuetude, it must be shown that the offence prohibited is not only practised without being checked, but is no longer considered or dealt with in this country as an offence against law" (Lord Justice General Inglis in Bute's Case, 1 *Couper's Rep.*, 495). Acts of the imperial parliament passed since the Union extend in general to Scotland, unless that country be excluded from their operation by express terms or necessary implication.

Ireland.—Originally the lord deputy appears to have held parliaments at his option, and their Acts were the only statutory law which applied to Ireland, except as far as judicial decisions had from motives of policy extended to that country the obligation of English statutes. In 1495 the Act of the Irish parliament known as Poyning's Law or the Statute of Drogheda enacted that all statutes lately made in England be deemed good and effectual in Ireland. This was construed to mean that all statutes made in England prior to the 18 Hen. VII. were valid in Ireland, but none of later date were to have any operation unless Ireland were specially named therein or unless adopted by the Irish parliament (as was done, for instance, by Yelverton's Act, 21 and 22 Geo. III. c. 48, I.). Another article of Poyning's Law secured an initiative of legislation to the English privy council, the Irish parliament having simply a power of acceptance or rejection of proposed legislation. The power of the parliament of Great Britain to make laws to bind the people of Ireland was declared by 6 Geo. I. c. 5. This Act and the article of Poyning's Law were repealed in 1782, and the short-lived independence of the parliament of Ireland was recognized by 23 Geo. III. c. 28. The application of Acts passed since the Union is the same as in the case of Scotland.

Colonies and Dependencies.—Acts of the imperial parliament do not extend to the Isle of Man, the Channel Islands, or the colonies, unless they are specially named therein. By 28 and 29 Vict. c. 63 any colonial law repugnant to the provisions of any Act of Parliament extending to the colony is void to the extent of such repugnancy, and no colonial law is to be void by repugnancy to the law of England unless it be repugnant to such an Act of Parliament. For colonies without representative legislatures the crown usually legislates, subject to the consent of parliament in particular cases. For instance, it was the opinion of the judicial committee of the privy council in 1876 that a cession of British territory in India to a native state would probably need the concurrence of the imperial parliament (Damodhar Gordhan *v.* Deoram Kanji, *Law Rep.*, 1 *Appeal Cases*, 332).

United States.—By the constitutions of many States English statute law, as it existed at the time of the separation from England, and as far as it is applicable, has been adopted as part of the law of the States. The United States and the State are not bound by an Act of Congress or a State law unless specially named. The States legislate for themselves within the limits of their own constitution and that of the United States. Here appears the striking difference between the binding force of a statute of the United Kingdom and an Act passed by congress or a State legislature. In the United Kingdom parliament is supreme; in the United States an Act is only of authority if it is in accordance with the constitution. The courts may declare an Act void if it contravene the constitution of the United States or of a State, so that practically the Supreme Court of the United States is the ultimate legislative authority. Examples of recent cases where the constitutionality of an Act has been contested will be found under PAYMENT and PRIVILEGE. The restrictions upon legislation contained in the constitution of the United States provide against the suspension of the writ of habeas corpus, except in case of rebellion or invasion, the passing of a bill of attainder or *ex post facto* law, the imposition of capitation or other direct tax, unless in accordance with a previous article of the constitution, or of a tax or duty on exports, the preference of the ports of one State over those of another, the drawing of money from the treasury except by appropriations made by law, and the grant of a title of nobility. The amended constitution contains further limitations, *e.g.*, the taking of private property for public use without just compensation, and the abridging of the right of citizens on account of race, colour, or previous condition of servitude. State legislation is limited by § 10:—"No State shall . . . make anything but gold and silver coin a tender in payment of debts, pass any bill of attainder, *ex post facto* law, or law impairing the obligation of contracts, or grant any title of nobility." The section further forbids imposition of duties on imports or exports or any duty of tonnage without consent of congress. State constitutions often contain further restrictions; among the more usual are provisions against laws with a retrospective operation, or impairing the obligation of contracts, or dealing with more than one subject to be expressed in the title. The time when a statute is to take effect after its passing is often fixed by State constitutions. The statutes of the United States were revised under the powers of an Act of Congress passed in 1874 (sess. 1. c. 333), and the volume of *Revised Statutes* (frequently amended since) was issued on February 22, 1875. Many of the States have also issued revised editions of their statutes. The rules of construction are in general agreement with those adopted in England. See Sedgwick, *Statutory Law*.

International Law.—The term statute is used by international jurists and civilians to denote the whole body of the municipal law of the state. In this sense statutes are either real, personal, or mixed. A real statute is that part of the law which deals directly with property, whether movable or immovable. A personal statute has for its object a person, and deals with questions of status, such as marriage, legitimacy, or infancy. A mixed statute affects both property and person, or, according to some authorities, it deals with acts and obligations. Personal statutes are of universal validity; real statutes have no extra-territorial authority. The determination of the class under which a particular law ought to fall is one of great difficulty, and one in which there is often a conflict of legal opinion. On the whole the division appears to have created more difficulties than it has solved, and it is rejected by Savigny as unsatisfactory. See Story, *Conflict of Laws*, §§ 12-16; Phillimore, *International Law*, vol. iv. ch. xvi. (J. W†.)

STATUTE MERCHANT AND STATUTE STAPLE were two old forms of security, long obsolete in practice, though references to them still occur in some modern statutes. They were originally permitted only among traders, for the benefit of commerce, but afterwards extended by 23 Hen. VIII. c. 6 to all subjects, whether traders or not. The creditor under either form of security was allowed to seize the goods and hold the lands of a defaulting debtor until satisfaction of his debt. While he held the lands he was termed tenant by statute merchant or by statute staple. In addition to the loss of his goods and lands the debtor was liable to be imprisoned.

STAUNTON, a city of the United States, the county-seat of Augusta county, Virginia, lies at the foot of the Blue Ridge Mountains, on the Lewis Creek (a tributary of the Shenandoah), 136 miles west-north-west of Richmond. It is the seat of the State lunatic asylum and of the State institution for the deaf and dumb and blind, and has besides an unusual number of important educational establishments. Iron-works, planing-mills, and flour-mills represent the manufacturing interest. The population was 5120 in 1870 and 6664 in 1880.

STAUNTON, HOWARD (1810-1874), Shakespearean scholar and writer on chess, was born about 1810. He was educated at Eton and Oxford, but left the university without taking a degree and settled in London, devoting much of his attention to the study of the English dramatists of the Elizabethan age. In conjunction with this he also took a great interest in the stage, and as an amateur once played Lorenzo to the Shylock of Edmund Kean. Between 1857 and 1860 he edited in monthly parts an edition of Shakespeare published by Routledge, which has been several times reissued, and must be ranked as superior, as regards both text and notes, to any previously published. His skill as a Shakespearean commentator, combining in a remarkable degree the acuteness and caution which qualified him to excel in chess, and disciplined to rare perfection by a thorough mastery of the literature of the period, is still more strikingly shown in his papers in the *Athenæum* on "Unsuspected Corruptions of Shakespeare's Text," commenced in October 1872. These formed part of the materials intended to be made use of in an improved edition of Shakespeare's works which he proposed to prepare, but which for a variety of reasons was never published. In 1864 he published a facsimile of the Shakespeare folio of 1623, and a finely illustrated work entitled *Memorials of Shakspeare*. He was also the author of the *Great Schools of England,—an Account of the Foundation, Endowments, and Discipline of the Chief Seminaries of Learning in England*, 1865. An account of his career as a chess-player, and a notice of his chief publications on the game, will be found under the heading CHESS (vol. v. pp. 601, 603). He died in London 22d June 1874.

STAVANGER, a seaport town of Norway, the administrative centre of an "amt" of the same name (population 114,164 in 1876), is situated on the west coast, on the south side of a beautiful fjord, about 127 miles north-west of Christiansand. A railway to connect Stavanger with Christiania has been planned, but as yet only the terminal portions have been constructed, the Stavanger portion, which runs south to Ekersund for 47 miles, being opened in 1878. The town is for the most part a collection of narrow and irregular streets, but signs of the wealth acquired by its shipping trade and herring fishery appear in the well-built stone houses erected since the great fire of 1860. In 1884 314 vessels (70,006 tons) entered the harbour and 267 (57,479 tons) cleared. Though the bishop's see was removed from Stavanger to Christiansand in 1685, the old cathedral of St Swithun's, founded by the English bishop Reinald in the end of the 11th century, and rebuilt after being burned down in 1272, still remains, and, next to the cathedral of Trondhjem, is the most interesting piece of Gothic architecture in Norway. The old episcopal palace of Kongsgaard is now a Latin school. The communal hospital is an important institution. The town dates from the 8th or 9th century and became the seat of a bishopric in the 13th. In 1801 the population of

Stavanger was only 2500, by 1855 it was 12,000, and by 1875 20,350

STAVROPOL, a government of Northern Caucasia, Russia, having an area of 26,530 square miles, and a population (rapidly increasing by Russian immigration) last returned at 637,893 It is bounded by Astrakhan and the province of the Don Cossacks on the N, Kubañ on the W, Terek on the S, and the Caspian Sea on the E, occupying the eastern part of the broad plains and steppes which fringe the main chain of CAUCASUS (*q v*) on the north In the western part of the government a broad undulating swelling, ranging from 1500 to 2000 feet above sea-level, extends northwards from the central mountain chain, in the southern part of this swelling, in the vicinity of Pyatigorsk, there is a group of sixteen mountains, 2800 to 4600 feet in height—the Beshtau,—which, as shown by Abich, ought to be considered as a porphyritic upheaval which took place at a point where the two predominant directions in Caucasus (south west to north-east and south-east to north-west) meet Northward and eastward of the above plateau are extensive steppes, from 400 to 200 feet above the sea, having gentle slopes both to the north (to the depression of the Manytch) and to the east (towards the low and dry steppes of the Caspian littoral) The geological structure of Stavropol is most interesting The mountains in the southern parts of Pyatigorsk consist of trachytic porphyries and volcanic rocks Numberless hot mineral springs (see PYATIGORSK) occur in this group, and earthquakes are most common in the region A broad belt of Miocene deposits, represented by the "steppe limestone" with *Mactra podolica*, girdles the hilly tracts, attaining a breadth of 40 miles or rather more, while the remainder of the steppes, which gently slope towards the Manytch and the Caspian, are occupied by the Post-Tertiary Caspian formation (loess)

Stavropol is chiefly watered by the Kuma and its tributaries (Podkumok, Karamyk, Buivola, &c), its basin being the most fertile part of the province, but the evaporation is so great that the Kuma never reaches the Caspian except in spring The Manytch is less a river than a series of lakes occupying a depression which formerly was a connecting channel between the Black Sea and the Caspian This channel has two slopes, the eastern sometimes discharging its scanty water-supply into the Kuma, while on the western slope the elongated lakes which fill up the depression drain into the Don, reaching it, however, only during spring. Two Yegorlyks (Great and Middle), the Kalaus, and the Tchogra (temporary tributaries of the Manytch) water the west part of Stavropol, while the Yeya and the Barsukly—a tributary of the Kubañ—rise in the district of Pyatigorsk On the whole, irrigation is scanty, and in the eastern steppes water is supplied only by cisterns Besides the few lakes of the Manytch depression, there are many smaller salt lakes around the Caspian Timber is scarce, even in the hilly tracts

The climate is severe Although Stavropol and Pyatigorsk both have an average yearly temperature of 48° Fahr, frosts of -22° Fahr are not uncommon, and the average winter temperature is only 28°7 at Stavropol (January, 25°, July, 71°). Yellow and other endemic fevers, sometimes very severe, are common on the low banks of the Kuma and Manytch

The region is traversed by both the great highways along the western shore of the Caspian (the Vladikavkaz and the Derbent routes), and accordingly several nations in their migrations have left stragglers on the steppes of Stavropol Thus we now find in these steppes Lamaite Kalmucks (about 10,000), Mohammedan Turcomans and Nogais (together about 60,000), as well as less considerable remains of several other tribes On the other hand, immigrants from Great and Little Russia, Poles, Germans, Esthonians, Greeks, and even a few Scots (in a colony close to Pyatigorsk) have settled in the most fertile and best watered parts of Stavropol in the course of the present century The Russian population is growing very rapidly, and already numbers upwards of 500,000

There are three administrative districts, the chief towns of which are Stavropol (35,470 inhabitants in 1884), Pyatigorsk (11,115), and Alexandrovskaya (8710), and a territory of nomad natives which occupies more than two-fifths of the entire area of the government

The educational returns for 1883 show 7 gymnasiums and "real schools," with 1081 boys and 491 girls, and 139 elementary schools, with only 5310 boys and 1034 girls

Agriculture is the chief occupation of the settled population, and so large is the harvest that no less than 16,000 labourers, attracted by high wages, come annually from European Russia to assist in gathering in the crops Large amounts of corn are exported both to the mountainous districts of Caucasus and to Russia (Rostoff-on-the-Don) Cattle-breeding is engaged in very largely, not only by the Kalmucks, Turcomans, and Nogais, but also by the Russians In 1884 Stavropol had 154,000 horses, 808,500 cattle, 2,540,000 sheep, 45,000 goats, 75,000 pigs, and 7500 camels Cattle and horses, as also wool, hair, hides, and sheepskins, are exported in considerable quantities A remarkable feature of Stavropol is the rapid growth among the Russian peasant population of a great variety of domestic trades both for local supply and for exportation Silk wares are now woven in the villages to such an extent as to become an important article of export to Russia Many other petty trades have also grown up of late, such as various kinds of cotton-weaving, the manufacture of leather wares, small metallic wares, and so on Manufactures proper (chiefly distillation) employed some 1000 persons in 1870, and their produce was estimated at about £140,000 per annum Since that time they have slowly expanded A brisk trade is carried on in the above-mentioned articles of export, and twenty-nine village fairs show an aggregate annual return of nearly £300,000

History—The northern slopes of Caucasus began to be colonized by Russians at a very early period, and as early as the 11th century part of the territory now occupied by Stavropol was known to Russian annalists as the Tmutarakañ principality, which had Russian princes A new attempt to colonize North Caucasus was made in the 16th century, under Ivan the Terrible, who married a Kabardian princess This was again unsuccessful, and it was not till 1711 that Russia began regularly to colonize the territory by Cossack settlements The military colonization was continued during the whole of last century, Kizlar was founded in 1736, Stavropol in 1776 or 1777 Immense tracts were given by Catherine II to her courtiers, who began to people them with serfs brought from Russia The flow of immigrants rapidly increased as soon as peace was firmly established, and it is still on the increase, especially since the emancipation of the serfs, so that Stavropol is rapidly becoming a Russian province, with a comparatively limited number of natives in the steppes of its eastern part

STAVROPOL, capital of the above province, is situated on a plateau 2000 feet above the sea, on the northern slope of the Caucasus, 360 miles to the north-west of Tiflis and 914 miles from Moscow It is connected by rail with Rostoff-on-the-Don Although founded only in 1776 for military purposes, it has rapidly grown, and has now a population of 35,500, while it is one of the best built provincial towns of the Russian empire It has wide streets, and its houses are mostly of stone, large gardens surround the houses, and numerous farms and gardens occupy the territory (nearly 50,000 acres) belonging to the town It is well provided with educational institutions, there being four gymnasia for boys and girls and several primary schools Nearly all the manufactures of the province are concentrated in Stavropol The trade is considerable, large numbers of cattle (more than 35,000 head annually) being sent to Moscow and St Petersburg, while tallow and more than 15,000 sheepskins are exported *via* Rostoff to Russia Corn is also exported to the value of nearly £300,000, while manufactured wares are imported to the value of nearly £150,000 Armenian, Georgian, and Persian merchants carry on a lively trade in local wares

STEAM-ENGINES AND OTHER HEAT-ENGINES

Definition of heat engines

1 A HEAT-ENGINE is a machine in which heat is employed to do mechanical work In all practical heat-engines, work is done through the expansion by heat of a fluid which overcomes resistance as it expands—in steam-engines by the expansion of water and water-vapour, in air-engines by the expansion of hot air, in gas-engines by the expansion of a burnt mixture of air and gas One of the most simple and historically one of the oldest types of heat-engines are guns, in which heat, generated by the combustion of an explosive, does work in giving energy of motion to a projectile But guns differ so widely from all other types, both in their purpose and in their development, that it is convenient to leave them out of account in treating of engines which may serve as prime movers to other mechanism

I EARLY HISTORY OF THE STEAM-ENGINE

Hero, 130 B C

2 The earliest notices of heat-engines are found in the *Pneumatica* of Hero of Alexandria (c 130 B C) Two contrivances described there deserve mention One is the æolipile, a steam reaction-turbine consisting of a spherical vessel pivoted on a central axis and supplied with steam through one of the pivots The steam escapes by bent pipes facing tangentially in opposite directions, at opposite ends of a diameter perpendicular to the axis The globe revolves by reaction from the escaping steam, just as a Barker's mill is driven by escaping water Another apparatus described by Hero (fig 1)[1] is interesting as the prototype of a class of engines which long afterwards became practically important A hollow altar containing air is heated by a fire kindled on it, the air in expanding drives some of the water contained in a spherical vessel beneath the altar into a bucket, which descends and opens the temple doors above by pulling round a pair of vertical posts to which the doors are fixed When the fire is extinguished the air cools, the water leaves the bucket, and the doors close In another device a jet of water driven out by expanding air is turned to account as a fountain

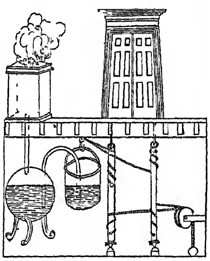

FIG 1 —Hero's Apparatus, 130 B C

3 From the time of Hero to the 17th century there is no progress to record, though here and there we find evidence that appliances like those described by Hero were used for trivial purposes, such as organ-blowing and the turning of spits The next distinct step was the publication in 1601 of a treatise on pneumatics by Giovanni Battista della Porta, in which he shows an apparatus similar to Hero's fountain, but with steam instead of air as the displacing fluid Steam generated in a separate vessel passes into a closed chamber containing water, from which a pipe (open under the water) leads out He also points out that the condensation of steam in the closed chamber may be used to produce a vacuum and suck up water from a lower level In fact, his suggestions anticipate very fully the engine which a century later became in the hands of Savery the earliest commercially successful steam-engine

Della Porta, 1601

[1] From Greenwood's translation of Hero's *Pneumatica*

De Caus

In 1615 Solomon de Caus gives a plan of forcing up water by a steam fountain which differs from Della Porta's only in having one vessel serve both as boiler and as displacement-chamber, the hot water being itself raised

Branca, 1629

4 Another line of invention was taken by Giovanni Branca (1629), who designed an engine shaped like a water-wheel, to be driven by the impact of a jet of steam on its vanes, and, in its turn, to drive other mechanism for various useful purposes But Branca's suggestion was unproductive, and we find the course of invention revert to the line followed by Della Porta and De Caus

Marquis of Worcester, 1663

5 The next contributor is one whose place is not easily assigned To Edward Somerset, second marquis of Worcester, appears to be due the credit of making the first useful steam-engine Its object was to raise water, and it worked probably like Della Porta's model, but with a pair of displacement-chambers, from each of which alternately water was forced by steam from an independent boiler, or perhaps by applying heat to the chamber itself, while the other vessel was allowed to refill Lord Worcester's description of the engine in his *Century of Inventions* (1663) is obscure, and no drawings are extant It is therefore difficult to say whether there were any distinctly novel features except the double action, in particular it is not clear whether the suction of a vacuum was used to raise water as well as the direct pressure of steam An engine of about two horse-power was in use at Vauxhall in 1656, and the walls of Raglan Castle contain traces of another, but neither Worcester's efforts nor those of his widow were successful in securing the commercial success of his engine

Savery, 1698

6 This success was reserved for Thomas Savery, who in 1698 obtained a patent for a water-raising engine, shown in fig 2 Steam is admitted to one of the oval vessels A, displacing water, which it drives up through the check-valve B When the vessel A is emptied of water, the supply of steam is stopped, and the steam already there is condensed by allowing a jet of cold water from a cistern above to stream over the outer surface of the vessel This produces a vacuum and causes water to be sucked up through the pipe C and the valve D Meanwhile, steam has been displacing water from the other vessel, and is ready to be condensed there The valves B and D open only upwards The supplementary boiler and furnace E are for feeding water to the main boiler, E is filled while cold and a fire is lighted under it, it then acts like the vessel of De Caus in forcing a supply of feed-water into the main boiler F The gauge-cocks G, G are an interesting feature of detail Another form of Savery's engine had only one displacement-chamber and worked intermittently In the use of artificial means to condense the steam, and in the application

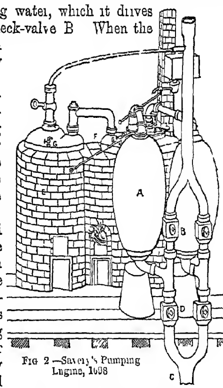

FIG 2 —Savery's Pumping Engine, 1698

of the vacuum so formed to ıaıse water by suctıon from a level lower than that of the engıne, Savery's engıne was probably an ımprovement on Worcester's, ın any case ıt found what Worcester's engıne had faıled to find,—consıdeıable employment ın pumpıng mınes and ın ıaısıng water to supply houses and towns, and even to drıve wateıwheels A seııous dıfficulty whıch prevented ıts general use ın mınes was the fact that the heıght through whıch ıt would lıft water was lımıted by the pressure the boıler and vessels could bear Pressures as hıgh as 8 or 10 atmospheres were employed—and that, too, wıthout a safety-valve—but Savery found ıt no easy matter to deal wıth hıgh-pressure steam, he complaıns that ıt melted hıs common solder, and forced hım, as Desagulıeıs tells us, "to be at the paıns and chaıge to have all hıs joınts soldered wıth spelter" Apart from thıs drawback the waste of fuel was enormous, from the condensatıon of steam whıch took place on the surface of the water and on the sıdes of the dısplacement-chambeı at each stroke, the consumptıon of coal, was, ın pıoportıon to the work done, some twenty tımes greater than ın a good modeın steamengıne In a tract called *The Mıneı's Fııend*, Saveıy alludes thus to the alternate heatıng and coolıng of the wateı-vessel "On the outsıde of the vessel you may see how the water goes out as well as ıf the vessel were trans parent, for so far as the steam contınues wıthın the vessel so far ıs the vessel dıy wıthout, and so veıy hot as scaıce to endure the least touch of the hand But as far as the water ıs, the saıd vessel wıll be cold and wet wheıe any water has fallen on ıt, whıch cold and moısture vanıshes as fast as the steam ın ıts descent takes place of the wateı" Before Saveıy's engıne was entıı ely dısplaced by ıts successor, Newcomen's, ıt was ımproved by Desagulıers, who applıed to ıt the safety valve (ınvented by Papın), and substıtuted condensatıon by a jet of cold water wıthın the vessel for the surface condensatıon used by Saveıy

7 So eaıly as 1678 the use of a pıston and cylınder (long before known as applıed to pumps) ın a heat engıne had been suggested by Jean Heautefeuılle, who proposed to use the explosıon of gunpowdeı eıther to ıaıse a pıston oı to foıce up wateı, or to pıoduce, by the subsequent coolıng of the gases, a partıal vacuum ınto whıch water mıght be sucked up Two years later Huygens descrıbed an engıne ın whıch the explosıon of gunpowder ın a cylındeı expelled part of the gaseous contents, afteı whıch the coolıng of the ıemaındeı caused a pıston to descend undeı atmosphei ıc pıessure, and the pıston ın descendıng dıd woık by ıaısıng a weıght

apın. 8 In 1690 Denıs Papın, who ten years befoıe had ınvented the safety-valve as an adjunct to hıs "dıgesteı," suggested that the condensatıon of steam should be employed to make a vacuum under a pıston prevıously raısed by the expansıon of the steam Papın's was the earlıest cylındeı and pıston steam-engıne, and hıs plan of usıng steam was that whıch afterwards took pıactıcal shape ın the atmosphei ıc engıne of Newcomen But

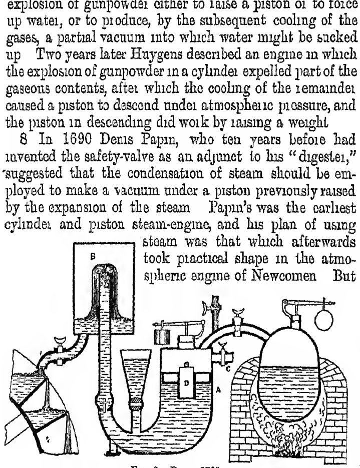

FIG 3 —Papın, 1705

hıs scheme was made unworkable by the fact that he proposed to use but one vessel as both boıler and cylınder A small quantıty of water was placed at the bottom of a cylınder and heat was applıed When the pıston had rısen the fire was ıemoved, the steam was allowed to cool, and the pıston dıd work ın ıts down-stıoke under the pressure of the atmosphere After hearıng of Savery's engıne ın 1705 Papın turned hıs attentıon to ımpıovıng ıt, and devısed a modıfied foı m, shown ın fig 3, ın whıch the dısplacementchamber A was a cylındeı, wıth a floatıng dıaphragm or pıston on the top of the water to keep the water and steam from dırect contact wıth one another The water was delıvered ınto a closed aır-vessel B, from whıch ıt ıssued ın a contınuous stream agaınst the vanes of a wateı-wheel After the steam had done ıts woık ın the dısplacementchamber ıt was allowed to escape by the stop-cock C ınstead of beıng condensed Papın's engıne was ın fact a non-condensıng sıngle-actıng steam-pump, wıth steam-cylınder and pump-cylınder ın one A curıous feature of ıt was the heater D, a hot mass of metal placed ın the dıaphragm for the puıpose of keepıng the steam dıy Among the many ınventıons of Papın was a boıler wıth an ınteı nal fire-box,—the eaı lıest example of a constructıon that ıs now almost unıveısal[1]

9. Whıle Papın was thus goıng back from hıs first notıon of a pıston-engıne to Savery's cruder type, a new ınventoı had appeaıed who made the pıston-engıne a practıcal success by sepaıatıng the boıler fıom the cylınder and by usıng (as Savery had done) aıtıficıal means to condense the steam This was Newcomen, who ın 1705, wıth hıs assıstant Cawley, gave the steam-engıne the foım shown ın fig 4 Steam admıtted fıom the boıler to the cylınder allowed the pıston to be ıaısed by a heavy counteıpoıse on the otheı sıde of the beam Then the steamvalve was shut and a jet of cold water entered the cylınder and condensed the steam The pıston was consequently foıced down by the pıessuıe of the atmospheıe and dıd work on the pump The next entıy of steam expelled the condensed water fıom the cylınder thıough an escape valve The pıston was kept tıght by a layer of wateı on ıts uppeı surface Condensatıon was at first effected by coolıng the outsıde of the cylınder, but the accıdental leakage of the packıng wateı past the pıston showed the advantage of condensıng by a jet of ınjectıon wateı, and thıs plan took the place of suıface condensatıon The engıne used steam whose pıessure was lıttle ıf at all greater than that of the atmosphere, sometımes ındeed ıt was worked wıth the manhole lıd off the boıleı

Newcomen's atmo spheric engine, 1705

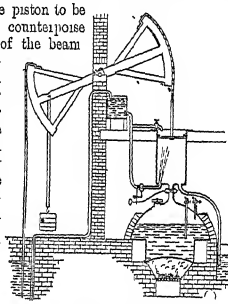

FIG 4 —Newcomen's Atmospheııc Engıne, 1705

10 About 1711 Newcomen's engıne began to be ıntroduced for pumpıng mınes, and ın 1713 a boy named Humphıey Potter, whose duty ıt was to open and shut the valves of an engıne he attended, made the engıne selfactıng by causıng the beam ıtself to open and close the valves by suıtable cords and catches Potter's ıude devıce was sımplıfied ın 1718 by Henry Beıghton, who suspended from the beam a rod called the plug-tree, whıch worked the valves by means of tappets By 1725 the engıne was ın common use ın collıerıes, and ıt held ıts place wıthout materıal change for about three-quarters of a century ın

Self-acting valve-gear Potter, Beighton, 1713–18

[1] Foı an account of Papın's ınventıons, see hıs *Lıfe and Letters*, by Dr E Gerland, Berlın, 1881

all Near the close of its career the atmospheric engine was much improved in its mechanical details by Smeaton, who built many large engines of this type about the year 1770, just after the great step which was to make Newcomen's engine obsolete had been taken by James Watt

Compared with Savery's engine, Newcomen's had (as a pumping-engine) the great advantage that the intensity of pressure in the pumps was not in any way limited by the pressure of the steam It shared with Savery's, in a scarcely less degree, the defect already pointed out, that steam was wasted by the alternate heating and cooling of the vessel into which it was led Though obviously capable of more extended uses, it was in fact almost exclusively employed to raise water,—in some instances for the purpose of turning water-wheels to drive other machinery Even contemporary writers complain of its "vast consumption of fuel," which appears to have been scarcely smaller than that of the engine of Savery

Watt, 1763 11 In 1763 James Watt, an instrument maker in Glasgow, while engaged by the university in repairing a model of Newcomen's engine, was struck with the waste of steam to which the alternate chilling and heating of the cylinder gave rise He saw that the remedy, in his own words, would lie in keeping the cylinder as hot as the steam that entered it. With this view he added to the engine a new organ—an empty vessel separate from the cylinder, into which the steam should be allowed to escape from the cylinder, to be condensed there by the application of cold water either outside or as a jet To preserve the vacuum in his condenser he added a pump called the air-pump, whose function was to pump from it the condensed steam and water of condensation, as well as the air which would otherwise accumulate by leakage or by being brought in with the steam or with the injection water Then as the cylinder was no longer used as a condenser he was able to keep it hot by clothing it with non-conducting bodies, and in particular by the use of a *steam-jacket*, or layer of hot steam between the cylinder and an external casing Further, and still with the same object, he covered in the top of the cylinder, taking the piston-rod out through a steam-tight stuffing-box, and allowed steam instead of air to press upon the piston's upper surface The idea of using a separate condenser had no sooner occurred to Watt than he put it to the test by constructing the apparatus shown in fig 5 There A is the cylinder, B a surface condenser, and C the air-pump The cylinder was filled with steam above the piston, and a vacuum was formed in the surface condenser B On opening the stop-cock D the steam rushed over from the cylinder and was condensed, while the piston rose and lifted a weight After several trials Watt patented his improvements in 1769, they are described in his specification in the following words, which, apart from their immense historical interest, deserve careful study as a statement of principles which to this day guide the scientific development of the steam engine —

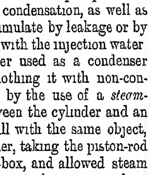

FIG 5 —Watt's Experimental Apparatus

Watt's specification, 1769 "My method of lessening the consumption of steam, and consequently fuel, in fire-engines, consists of the following principles —

"*First*, That vessel in which the powers of steam are to be employed to work the engine, which is called the cylinder in common fire engines, and which I call the steam vessel, must, during the whole time the engine is at work, be kept as hot as the steam that enters it, first by enclosing it in a case of wood, or any other materials that transmit heat slowly, secondly, by surrounding it with steam or other heated bodies, and, thirdly, by suffering neither water nor any other substance colder than the steam to enter or touch it during that time

"*Secondly*, In engines that are to be worked wholly or partially by condensation of steam, the steam is to be condensed in vessels distinct from the steam vessels or cylinders, although occasionally communicating with them, these vessels I call condensers, and, whilst the engines are working, these condensers ought at least to be kept as cold as the air in the neighbourhood of the engines, by application of water or other cold bodies

"*Thirdly*, Whatever air or other elastic vapour is not condensed by the cold of the condenser, and may impede the working of the engine, is to be drawn out of the steam-vessels or condensers by means of pumps, wrought by the engines themselves, or otherwise

"*Fourthly*, I intend in many cases to employ the expansive force of steam to press on the pistons, or whatever may be used instead of them, in the same manner in which the pressure of the atmosphere is now employed in common fire engines In cases where cold water cannot be had in plenty, the engines may be wrought by this force of steam only, by discharging the steam into the air after it has done its office

"*Sixthly*, I intend in some cases to apply a degree of cold not capable of reducing the steam to water, but of contracting it considerably, so that the engines shall be worked by the alternate expansion and contraction of the steam

"*Lastly*, Instead of using water to render the pistons and other parts of the engine air and steam tight, I employ oils, wax, resinous bodies, fat of animals, quicksilver and other metals in their fluid state"

The fifth claim was for a rotary engine, and need not be quoted here

The "common fire-engine" alluded to was the steam-engine, or, as it was more generally called, the "atmospheric" engine of Newcomen Enormously important as Watt's first patent was, it resulted for a time in the production of nothing more than a greatly improved engine of the Newcomen type, much less wasteful of fuel, able to make faster strokes, but still only suitable for pumping, still single-acting, with steam admitted during the whole stroke, the piston, as before, pulling the beam by a chain working on a circular arc The condenser was generally worked by injection, but Watt has left a model of a surface condenser made up of small tubes, in every essential respect like the condensers now used in marine engines

12 Fig 6 is an example of the Watt pumping-engine of this period It should be noticed that, although the top of the cylinder is closed and steam has access to the upper side of the piston, this is done only to keep the cylinder and piston warm The engine is still single-acting; the steam in the upper side merely plays the part which was played in Newcomen's engine by the atmosphere, and it is the lower end of the cylinder alone that is ever put in communication with the condenser There are three valves, — the "steam" valve *a*, the "equilibrium" valve *b*, and the "exhaust" valve *c* At the beginning of the down-stroke *c* is opened to produce a vacuum below the piston and *a* is Watt's pumping engine, 1769

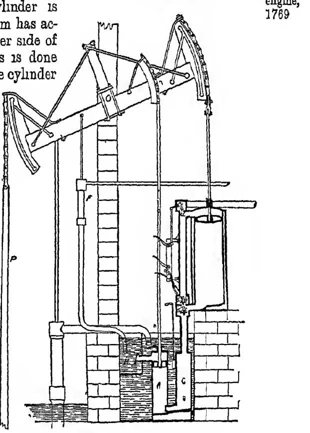

FIG 6 —Watt's Single-Acting Engine, 1769.

opened to admit steam above it. At the end of the down-stroke *a* and *c* are shut and *b* is opened. This puts the two sides in equilibrium, and allows the piston to be pulled up by the pump-rod P, which is heavy enough to serve as a counterpoise. C is the condenser, and A the air-pump, which discharges into the hot well H, whence the supply of the feed-pump F is drawn.

Rotative engine.

13. In a second patent (1781) Watt describes the "sun-and-planet" wheels and other methods of making the engine give continuous revolving motion to a shaft provided with a fly wheel. He had invented the crank and connecting-rod for this purpose, but it had meanwhile been patented by one Pickard, and Watt, rather than make terms with Pickard, whom he regarded as a plagiarist of his own ideas, made use of his sun-and-planet motion until the patent on the crank expired. The reciprocating motion of earlier forms had served only for pumping; by this invention Watt opened up for the steam-engine a thousand other channels of usefulness. The engine was still single-acting; the connecting rod was attached to the far end of the beam, and that carried a counterpoise which served to raise the piston when steam was admitted below it.

Double action.

14. In 1782 Watt patented two further improvements of the first importance, both of which he had invented some years before. One was the use of double action, that is to say, the application of steam and vacuum to each side of the piston alternately.

Expansion of steam.

The other (invented as early as 1769) was the use of steam expansively, in other words the plan (now used in all engines that aim at economy of fuel) of stopping the admission of steam when the piston had made only a part of its stroke, and allowing the rest of the stroke to be performed by the expansion of the steam already in the cylinder. To let the piston push as well as pull the end of the beam Watt devised his so called parallel motion, an arrangement of

Parallel motion.

links connecting the piston rod head with the beam in such a way as to guide the rod to move in a very nearly straight line. He further added the throttle valve, for regulating the rate of admission of steam, and

Governor.

the centrifugal governor, a double conical pendulum, which controlled the speed by acting on the throttle-valve. The stage of development reached at this time is illustrated by the engine of fig. 7 (from Stuart's *History of the Steam-Engine*), which shows the parallel motion *pp*, the governor *g*, the throttle-valve *t*, and a pair of steam and exhaust valves at each end of the cylinder.

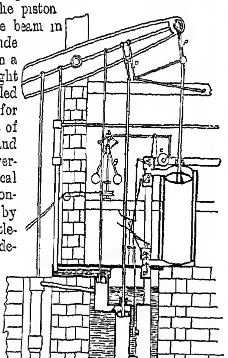

FIG. 7.—Watt's Double Acting Engine, 1782.

Indicator.

Among other inventions of Watt were the "indicator," by which diagrams showing the relation of the steam-pressure in the cylinder to the movement of the piston are automatically drawn, a steam tilt-hammer, and also a steam locomotive for ordinary roads,—but this invention was not prosecuted.

In partnership with Matthew Boulton, Watt carried on in Birmingham the manufacture and sale of his engines with the utmost success, and held the field against all rivals in spite of severe assaults on the validity of his patents. Notwithstanding his accurate knowledge of the advantage to be gained by using steam expansively he continued to employ only low pressures—seldom more than 7 lb per square inch over that of the atmosphere. His boilers were fed, as Newcomen's had been, through an open pipe which rose high enough to let the column of water in it balance the pressure of the steam.

Rating of engines by "horse-power."

He introduced the term "horse-power" as a mode of rating engines, defining one horse-power as the rate at which work is done when 33,000 lb are raised one foot in one minute. This estimate was based on trials of the work done by horses; it is excessive as a statement of what an average horse can do, but Watt purposely made it so in order that his customers might have no reason to complain on this score.

Non condensing engine.

15. In the fourth claim in Watt's first patent, the second sentence describes a non condensing engine, which would have required steam of a higher pressure. This, however, was a line of invention which Watt did not follow up, perhaps because so early as 1725 a non-condensing engine had been described by Leupold in his

Leupold, 1725.

Theatrum Machinarum. Leupold's proposed engine is shown in fig. 8, which makes its action sufficiently clear. Watt's aversion to high-pressure steam was strong, and its influence on steam-engine practice long survived the expiry of his patents. So much indeed was this the case that the terms "high-pressure" and "non condensing" were for many years synonymous, in contradistinction to the "low-pressure" or condensing engines of Watt. This nomenclature no longer holds; in modern practice many condensing engines use as high pressures as non-condensing engines, and by doing so are able to take advantage of Watt's great invention of expansive working to a degree which was impossible in his own practice.

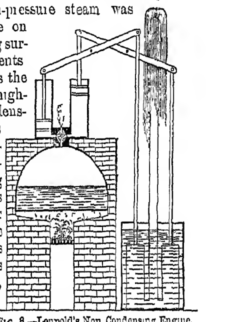

FIG. 8.—Leupold's Non Condensing Engine, 1725.

High pressure steam. Trevithick and Evans.

16. The introduction of the non-condensing and, at that time, relatively high-pressure engine, was effected in England by Trevithick and in America by Oliver Evans about 1800. Both Evans and Trevithick applied their engines to propel carriages on roads, and both used for boiler a cylindrical vessel with a cylindrical flue inside—the construction now known as the Cornish boiler. In partnership with Bull, Trevithick had previously made direct acting pumping-engines, with an inverted cylinder set over and in line with the pump rod, thus dispensing with the beam that had been a feature in all earlier forms. But in these "Bull" engines, as they were called, a condenser was used, or, rather, the steam was condensed by a jet of cold water in the exhaust-pipe, and Boulton and Watt successfully opposed them as infringing Watt's patents. To Trevithick belongs the distinguished honour of being the first to use a steam carriage on a railway; in 1804 he built a locomotive in the modern sense, to run on what had formerly been a horse tramway in Wales, and it is noteworthy that the exhaust steam was discharged into the funnel to force the furnace draught, a device which, 25 years later, in the hands of George Stephenson, went far to make the locomotive what it is to day. In this connexion it may be added that as early as 1769 a steam-

Cugnot, 1769. carriage for roads had been built by Cugnot in France, who used a pair of single acting high-pressure cylinders to turn a driving axle step by step by means of pawls and ratchet-wheels. To the initiative of Evans may be ascribed the early general use of high-pressure steam in the United States, a feature which for many years distinguished American from English practice.

Compound engine Hornblower, 1781. 17. Amongst the contemporaries of Watt one name deserves special mention. In 1781 Jonathan Hornblower constructed and patented what would now be called a compound engine, with two cylinders of different sizes. Steam was first admitted into the smaller cylinder, and then passed over into the larger, doing work against a piston in each. In Hornblower's engine the two cylinders were placed side by side, and both pistons worked on the same end of a beam overhead. This was an instance of the use of steam expansively, and as such was earlier than the patent, though not earlier than the invention, of expansive working by Watt. Hornblower was crushed by the Birmingham firm for infringing their patent in the use of a separate condenser and air-pump. The compound engine was revived in 1804 by Woolf, with whose name it is often associated. Using steam of fairly high pressure, and cutting off the supply before the end of the stroke in the small cylinder, Woolf expanded the steam to several times its original volume. Mechanically the double-cylinder compound engine has this advantage over an engine in which the same amount of expansion is performed in a single cylinder, that the sum of the forces exerted by the two pistons in the compound engine varies less throughout the action than the force exerted by the piston of the single-cylinder engine. This advantage may have been clear to Hornblower and Woolf, and to other early users of compound expansion. But another and probably a more important merit of the system lies in a fact of which neither they nor for many years their followers in the use of compound engines were aware—the fact that by dividing the whole range of expansion into two parts the cylinders in which these are separately performed are subject to a reduced range of fluctuation in their temperature. This, as will be afterwards pointed out, limits to a great extent a source of waste which is present in all steam-engines, the waste which results from the heating and cooling of the metal by its alternate contact with hot and cooler steam. The system of compound expansion is now used in nearly all large engines that pretend to economy. Its introduction forms the only great improvement which the steam-engine has undergone since the time of Watt, and we are able to recognize it as a very important step in the direction set forth in his "first principle," that the cylinder should be kept as hot as the steam that enters it.

Woolf, 1804.

Cornish engine. 18. Woolf introduced the compound engine somewhat widely about 1814, as a pumping engine in the mines of Cornwall. But here it met a strong competitor in the high-pressure single-cylinder engine of Trevithick, which had the advantage of greater simplicity in construction. Woolf's engine fell into comparative disuse, and the single-cylinder type took a form which, under the name of the Cornish pumping engine, was for many years famous for its great economy of fuel. In this engine the cylinder was set under one end of a beam, from the other end of which hung a heavy rod which operated a pump at the foot of the shaft. Steam was admitted above the piston for a short portion of the stroke, thereby raising the pump-rod, and was allowed to expand for the remainder. Then an equilibrium valve, connecting the space above and below the piston, as in fig. 6, was opened, and the pump-rod descended, doing work in the pump and raising the engine piston. The large mass which had to be started and stopped at each stroke served by its inertia to counterbalance the unequal pressure of the steam, for the ascending rods stored up energy of motion in the early part of the stroke, when the steam pressure was greatest, and gave out energy in the later part, when expansion had greatly lowered the pressure. The frequency of the stroke was controlled by a device called a cataract, consisting of a small plunger pump, in which the plunger, raised at each stroke by the engine, was allowed to descend more or less slowly by the escape of fluid below it through an adjustable orifice, and in its descent liberated catches which held the steam and exhaust valves from opening. A similar device controlled the equilibrium valve, and could be set to give a pause at the end of the piston's down-stroke, so that the pump cylinder might have time to become completely filled. The Cornish engine is interesting as the earliest form which achieved an efficiency comparable with that of good modern engines. For many years monthly reports were published of the "duty" of these engines, the "duty" being the number of foot-pounds of work done per bushel or (in some cases) per cwt of coal. The average duty of engines in the Cornwall district rose from about 18 millions of foot-pounds per cwt. of coal in 1813 to 68 millions in 1844, after which less effort seems to have been made to maintain a high efficiency.[1] In individual cases much higher results were reported, as in the Fowey Consols engine, which in 1835 was stated to have a duty of 125 millions. This (to use a more modern mode of reckoning) is equivalent to the consumption of only a little more than $1\frac{3}{4}$ lb of coal per horse-power per hour—a result surpassed by very few engines in even the best recent practice. It is difficult to credit figures which, even in exceptional instances, place the Cornish engine of that period on a level with the most efficient modern engines—in which compound expansion and higher pressure combine to make a much more perfect thermodynamic machine; and apart from this there is room to question the accuracy of the Cornish reports. They played, however, a useful part in the process of steam-engine development by directing attention to the question of efficiency, and by demonstrating the advantage to be gained by high pressure and expansive working, at a time when the theory of the steam engine had not yet taken shape.

Compound engine. 19. The final revival of the compound engine did not occur until about the middle of the century, and then several agencies combined to effect it. In 1845 M'Naught introduced a plan of improving beam engines of the original Watt type, by adding a high-pressure cylinder whose piston acted on the beam between the centre and the fly-wheel end. Steam of higher pressure than had formerly been used, after doing work in the new cylinder, passed into the old or low-pressure cylinder, where it was further expanded. Many engines whose power was proving insufficient for the extended machinery they had to drive were "M'Naughted" in this way, and after conversion were found not only to yield more power but to show a marked economy of fuel. The compound form was selected by Mr Pole for the pumping engines of Lambeth and other waterworks about 1850; in 1854 John Elder began to use it in marine engines; in 1857 Mr Cowper added a steam-jacketed intermediate reservoir for steam between the high and low pressure cylinders, which made it unnecessary for the low-pressure piston to be just beginning when the other piston was just ending its stroke. As facilities increased for the use of high-pressure steam, compound expansion became more and more general, its advantage becoming more conspicuous with every

[1] *Min. Proc. Inst. C.E.*, vol. xxiii., 1863.

increase in boiler pressure—until now there are few large land engines and scarcely any marine engines that do not employ it In marine practice, where economy of fuel is a much more important factor in determining the design than it is on land, the principle of compound expansion has lately been greatly extended by the introduction of triple and even quadruple expansion engines, in which the steam is made to expand successively in three or in four cylinders Even in the building of locomotive engines, where other considerations are of more moment than the saving of coal, the system of compound expansion is beginning to find a place

The growth of compound expansion has been referred to at some length, because it forms the most distinctive improvement which the steam-engine has undergone since the time of Watt For the rest, the progress of the steam-engine has consisted in its adaptation to particular uses, in the invention of features of mechanical detail, in the recognition and application of thermodynamical principles, and in improved methods of engineering construction by which it has profited in common with all other machines These have in particular made possible the use of steam of eight or ten times the pressure of that employed by Watt

Application to locomotives

20 The adaptation of the steam engine to railways, begun by Trevithick, became a success in the hands of George Stephenson, whose engine the "Rocket," when tried along with others on the Stockton and Darlington road in 1829, not only distanced its competitors but settled once and for all the question whether horse traction or steam traction was to be used on railways The principal features of the "Rocket" were an improved steam-blast for urging the combustion of coal and a boiler (suggested by Booth, the secretary of the railway) in which a large heating surface was given by the use of many small tubes through which the hot gases passed Further, the cylinders, instead of being vertical as in earlier locomotives, were set in at a slope, which was afterwards altered to a position more nearly horizontal To these features there was added later the "link motion," a contrivance which enabled the engine to be easily reversed and the amount of expansion to be readily varied In the hands of George Stephenson and his son Robert the locomotive took a form which has been in all essentials maintained by the far heavier locomotives of to-day

Application to steam boats

21. The first practical steamboat was the tug "Charlotte Dundas," built by William Symmington, and tried in the Forth and Clyde Canal in 1802 A Watt double-acting condensing engine, placed horizontally, acted directly by a connecting-rod on the crank of a shaft at the stern, which carried a revolving paddle-wheel The trial was successful, but steam towing was abandoned for fear of injuring the banks of the canal Ten years later Henry Bell built the "Comet," with side paddle-wheels, which ran as a passenger steamer on the Clyde, but an earlier inventor to follow up Symmington's success was the American Robert Fulton, who, after unsuccessful experiments on the Seine, fitted a steamer on the Hudson in 1807 with engines made to his designs by Boulton and Watt, and brought steam navigation for the first time to commercial success

Theory of steam-engine

22 The early inventors had little in the way of theory to guide them Watt had the advantage, which he acknowledges, of a knowledge of Black's doctrine of latent heat, but there was no philosophy of the relation of work to heat until long after the inventions of Watt were complete The theory of the steam-engine as a

Carnot

heat engine dates from 1824, when Carnot published his *Reflexions sur la Puissance Motrice du Feu*, and showed that heat does work only by being let down from a higher to a lower temperature But Carnot had no idea that any of the heat disappears in the process, and it was not until the doctrine of the conservation of energy was established in 1843 by the experiments of Joule that the theory of heat engines began a vigorous growth From 1849 onwards the science of thermodynamics was developed with extraordinary rapidity by Clausius, Rankine, and Thomson, and was applied, especially by Rankine, to practical problems in the use of steam The publication in 1859 of Rankine's *Manual of the Steam Engine* formed an epoch in the history of the subject by giving inventors a new basis, outside of mere empiricism, from which they could push on the development of the steam-engine

Joule

Clausius, Rankine, Thomson

Unfortunately, however, for its bearing on practice, the theory of the steam-engine was to a great extent founded on certain simplifying assumptions which experience has now shown to be far from correct It was assumed that the cylinder and piston might be treated as behaving to the steam like non-conducting bodies,—that the transfer of heat between the steam and the metal was negligibly small Rankine's calculations of steam-consumption, work, and thermodynamic efficiency involve this assumption, except in the case of steam-jacketed cylinders, where he estimates that the steam in its passage through the cylinder takes just enough heat from the jacket to prevent a small amount of condensation which would otherwise occur as the process of expansion goes on If the transfer of heat from steam to metal could be overlooked, the steam which enters the cylinder would remain during admission as dry as it was before it entered, and the volume of steam consumed per stroke would correspond with the volume of the cylinder up to the point of cut-off It is here that the actual behaviour of steam in the cylinder diverges most widely from the behaviour which the theory assumes When steam enters the cylinder it finds the metal chilled by the previous exhaust, and a portion of it is at once condensed This has the effect of increasing, often very largely, the volume of boiler steam required per stroke As expansion goes on the water that was condensed during admission begins to be re-evaporated from the sides of the cylinder, and this action is often prolonged into the exhaust In a later chapter the effect which this exchange of heat between the metal of the cylinder and the working fluid produces on the economy of the engine will be discussed, and an account will be given of experimental means by which we may examine the amount of steam that is initially condensed and trace its subsequent re-evaporation It is now recognized that any theory which fails to take account of these exchanges of heat fails also to yield even comparatively correct results in calculating the relative efficiency of various steam pressures or various ranges of expansion But the exchanges of heat are so complex that there seems little prospect of submitting them to any comprehensive theoretical treatment, and we must rather look for help in the future development of engines to the scientific analysis of experiments with actual machines Much careful work of this kind has already been done by Hirn and others, and there is room for much more Questions relating to the influence (on heat-engine economy) of speed, of pressure, of ratio of expansion, of jacketing, of compound expansion, or of superheating must in the main be settled by an appeal to experiment,—experiment guided and interpreted at every step by reference to the principles of thermodynamics and the theory of steam

II. THEORY OF HEAT-ENGINES

Laws of thermodynamics.

23. A heat engine acts by taking in heat, converting a part of the heat received into mechanical energy, which appears as the work done by the engine, and rejecting the remainder, still in the form of heat. The theory of heat engines comprises the study of the amount of work done, in its relation to the heat supplied and to the heat rejected. The theory is based on the two laws of thermodynamics, which may be stated here as follows:—

LAW 1. *When mechanical energy is produced from heat, 1 thermal unit of heat goes out of existence for every 772 foot-pounds of work done, and, conversely, when heat is produced by the expenditure of mechanical energy, 1 thermal unit of heat comes into existence for every 772 foot-pounds of work spent.*

The "thermal unit" is the heat required to raise the temperature of 1 lb of water 1 degree Fahr. when at its temperature of maximum density. The equivalent quantity of work, 772 foot pounds, was determined by the experiments of Joule, and is called Joule's equivalent. Later researches by Joule and others have indicated that this number is probably too small; it should perhaps be as much as 774 foot-pounds. Joule's original value is still generally used by engineers, and as it enters into many published tables it may conveniently be adhered to until its accuracy is more definitely disproved. Since a definite number of foot pounds are equivalent to 1 thermal unit, we may, if we please, express quantities of work in thermal units, or quantities of heat in foot pounds; the latter practice will frequently be found useful.

LAW 2. *It is impossible for a self-acting machine, unaided by any external agency, to convey heat from one body to another at a higher temperature.*

This is the form in which the second law has been stated by Clausius. Another statement of it, different in form but similar in effect, has been given by Thomson. Its force may not be immediately obvious, but it will be shown below that it introduces a most important limitation of the power which any engine has of converting heat into work. So far as the first law shows, there is nothing to prevent the whole heat taken in by the engine from changing into mechanical energy. In consequence of the second law, however, no heat engine converts, or can convert, more than a small fraction of the heat supplied to it into work; a large part is necessarily rejected as heat. The ratio

$$\frac{\text{Heat converted into work}}{\text{Heat taken in by the engine}}$$

is a fraction always much less than unity. This ratio is called the *efficiency* of the engine considered as a heat-engine.

Working substance.

24. In every heat engine there is a *working substance* which takes in and rejects heat, thereby suffering changes of form, or more commonly of volume, and does work by overcoming resistance to these changes of form or volume. The working substance may be gaseous, liquid, or solid. We can, for example, imagine a heat-engine in which the working substance is a long metallic rod, arranged to act as the pawl of a ratchet-wheel with fine teeth. Let the rod be heated so that it elongates sufficiently to drive the wheel forward through the space of one tooth. Then let the rod be cooled (say by applying cold water), the wheel being meanwhile held from returning by a separate click or detent. The rod, on cooling, will retract so as to engage itself with the next succeeding tooth, which may then be driven forward by heating the rod again, and so on. To make it evident that such an engine would do work, we have only to suppose that the ratchet wheel carries round with it a drum by which a weight is wound up. We have, then, a complete heat engine, in which the working substance is a solid rod, which receives heat by being brought into contact with some source of heat at a comparatively high temperature, transforms a small part of this heat into work, and rejects the remainder to what we may call a receiver of heat, at a comparatively low temperature.

Degradation of temperature.

The greater part of the heat may be said simply to pass through the engine, from the source to the receiver, *becoming degraded as regards temperature* as it goes. We shall see presently that this is typical of the action of all heat-engines; when they are doing work, the heat which they reject is rejected at a temperature lower than that at which it is taken in. They convert some heat into work only by letting down a much larger quantity of heat from a high to a relatively low temperature. The action is analogous to that of a water wheel, which does work by letting down water from a high to a lower level, but with this important difference that in the transfer which occurs in heat-engines an amount of heat disappears which is equivalent to the work done.

Fluid working substance.

25. In almost all actual heat-engines the working substance is a fluid. In some it is air, in some a mixture of several gases. In the steam-engine the working fluid is a mixture (in varying proportions) of water and steam.

Work by changes of volume.

With a fluid for working substance, work is done by changes of volume only; its amount depends solely on the relation of pressure to volume during the change, and not at all on the form of the vessels in which the change takes place. Let a diagram be drawn (fig. 9) in which the relation of the intensity of pressure to the volume of any supposed working substance is graphically exhibited by the line ABC, where AM, CN are pressures and AP, CQ are volumes, then the work done by the substance in expanding from A to C is the area of the figure MABCN. And similarly, if the substance be compressed from C back to its original volume in such a manner that the line CDA represents the relation of pressure and volume during compression, the work done *upon* the substance is the figure NCDAM. Taking the two operations together, we find that the substance has done a net amount of work equal to the area of the shaded figure ABCDA, or $\int PdV$. This is an example and a generalization of the method of representing work which Watt introduced by his invention of the indicator; the figure ABCDA may be called the indicator diagram of the supposed action.

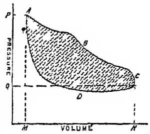

Fig. 9.

Cycle of operations of working substance.

26. Generally in heat engines the working substance returns periodically to the same state of temperature, pressure, volume, and physical condition. When this has occurred the substance is said to have passed through a complete cycle of operations. For example, in a condensing steam engine, water taken from the hot-well is pumped into the boiler, it then passes into the cylinder as steam, passes thence into the condenser, and thence again into the hot-well; it completes the cycle by returning to the same condition as at first. In other less obvious cases, as in that of the non-condensing steam engine, a little consideration will show that the cycle is completed, not indeed by the same portion of working substance being returned to the boiler, but by an equal quantity of water being fed to it, while the steam which has been discharged into the atmosphere cools to the temperature of the feed. In the theory of heat-engines it is of the first importance to consider (as was first done by Carnot in 1824) the cycle of operations performed by the working substance as a complete whole. If we stop short of the completion of a cycle matters are complicated by the fact that the substance is in a state different from its initial state, and may therefore have changed its stock of internal energy. After a complete cycle, on the other hand, we know at once that, since the condition is the same, the internal energy of the substance is the same as at first, and therefore—

Heat taken in = work done + heat rejected.

Engine with a perfect gas.

27. It will serve our purpose best to approach the theory of heat engines by considering, in the first instance, the action of an engine in which the working substance is any one of the so-called permanent gases, or a mixture of them, such as air. The word permanent, as applied to a gas, can now[1] be understood only as meaning that the gas is liquefied with difficulty—either by the use of extremely low temperature or extremely high pressure or both. So long as gases are under conditions of pressure and temperature widely different from those which produce liquefaction, they conform very approximately to certain simple laws—laws which may be regarded as *rigorously* applicable to ideal substances called *perfect* gases. After stating these laws briefly we shall examine the efficiency of a heat-engine using a gas in a certain manner as working substance, and then show that the conclusion so derived has a general application to all heat-engines whatsoever. In this procedure there is no sacrifice of generality, and a part of the process is of independent service in the discussion of actual air engines.

Laws of the permanent gases. Boyle's law.

28. The laws of the permanent gases are the following:—

LAW 1 (Boyle). *The volume of a given mass of gas varies inversely as the pressure, the temperature being kept constant.*

Thus, if V be the volume of 1 lb of a gas in cubic feet, and P the pressure in pounds per square foot, so long as the temperature is unchanged—

$$P \propto V^{-1}, \text{ or } PV = \text{constant}.$$

For air the value of the constant is 26220 when the temperature is 32° F.

Charles's law.

29. LAW 2 (Charles). *Under constant pressure equal volumes of different gases increase equally for the same increment of temperature. Also, if a gas be heated under constant pressure, equal increments of its volume correspond very nearly to equal intervals of temperature as determined by the scale of a mercury thermometer.*

Thus, let us take, say, 493 cubic inches of hydrogen, also of oxygen, of air, &c., all at 32° F., and, keeping each at a constant pressure (not necessarily the same for all), heat all so that their temperature rises 1° F. We shall find that each has expanded by sensibly the same amount and now occupies 494 cubic inches. And further, if we heat any one through another 1° F. to 34° F., we shall find that its volume is now 495 cubic inches, and so on. Thus for any gas, kept at constant pressure, if the volume was

[1] Since the liquefaction of hydrogen and other gases by MM. Cailletet and Pictet.

it would be

$$\begin{aligned} &493 \text{ at } 32^\circ \text{ F.},\\ &492 \text{ at } 31^\circ \text{ F.},\\ &\ldots\\ &461 \text{ at } 0^\circ \text{ F.},\end{aligned}$$

and finally $\quad 0 \text{ at } -461^\circ \text{ F.},$

provided the same law were to hold at indefinitely low temperatures. This we may assume to be the case with a perfect gas, although any actual gas would change its physical state long before so low a temperature were reached.

Absolute temperature. This result may be concisely expressed by saying that if we reckon temperature, not from the ordinary zero but from a point 461° below the zero of Fahrenheit's scale, the volume of a given quantity of a gas, kept at constant pressure, is proportional to the temperature reckoned from that zero. Temperatures so reckoned are called absolute temperatures, and the point −461° F. is called the absolute zero of temperature. Denoting any temperature according to the ordinary scale by t, and the corresponding absolute temperature by τ, we have

$$\tau = t + 461 \text{ on the Fahrenheit scale,}$$

and

$$\tau = t + 274 \text{ on the Centigrade scale.}$$

Charles's law shows that if temperatures be measured by thermometers in which the expanding substance is air, hydrogen, oxygen, or any other permanent gas, and, if those intervals of temperature be called equal which correspond to equal amounts of expansion, then the indications of these thermometers always agree very closely with each other, and also agree, though less closely, with the indications of a mercury thermometer. We shall see later that the theory of heat engines affords a means of forming a thermometric scale which is independent of the properties, as to expansion, of any substance, and that this scale coincides with the scale of a perfect gas thermometer, a fact which justifies the use of the term absolute, as applied to temperatures measured by the expansion of a gas.

30. Combining laws 1 and 2, we have, for a given mass of any gas,

$$PV = c\tau,$$

where c is a constant depending on the specific density of the gas and on the units in which P and V are measured. In what follows we shall assume that P is measured in pounds per square foot, that V is the volume of 1 lb in cubic feet, and that τ is the absolute temperature in Fahrenheit degrees. In air, with these units,

$$PV = 53.18\tau.$$

Regnault's law. 31. LAW 3 (Regnault). *The specific heat at constant pressure is constant for any gas.*

Specific heat at constant pressure. By specific heat at constant pressure is meant the heat taken in by 1 lb of a substance when its temperature rises 1° F., while the pressure remains unchanged—the volume of course increasing. The law states that this quantity is the same for any one gas, no matter what be the temperature, or what the constant pressure, at which the process of heating takes place.

Specific heat at constant volume. 32. Another important quantity in the theory of heat engines is the specific heat at constant volume, that is, the heat taken in by 1 lb of the substance when its temperature rises 1° F. while the volume remains unchanged—the pressure of course increasing. We shall denote specific heat at constant pressure by K_p and specific heat at constant volume by K_v. Let 1 lb of a gas be heated at constant pressure P from temperature τ_1 to temperature τ_2 (absolute). Let V_1 be the volume at τ_1 and V_2 the volume at τ_2. Heat is taken in, and external work is done by the expansion of the gas, namely—

$$\text{Heat taken in} = K_p(\tau_2 - \tau_1)$$

$$\text{Work done} = P(V_2 - V_1) = c(\tau_2 - \tau_1).$$

The difference between these quantities, or $(K_p - c)(\tau_2 - \tau_1)$, is the amount by which the stock of internal energy possessed by the gas has increased during the process. We shall see presently that this gain of internal energy would have been the same had the gas passed in any other manner from τ_1 to τ_2.

Joule's law. 33. LAW 4 (Joule). *When a gas expands without doing external work, and without taking in or giving out heat, its temperature does not change.*

To prove this, Joule connected a vessel containing compressed gas with another vessel that was empty, by means of a pipe with a closed stop cock. Both vessels were immersed in a tub of water and were allowed to assume a uniform temperature. Then the stop-cock was opened, the gas expanded without doing external work, and finally the temperature of the water in the tub was found to have undergone no change. The temperature of the gas was unaltered, and no heat had been taken in or given out by it.

Internal energy of a gas depends only on temperature. 34. Since the gas had neither gained nor lost heat, and had done no work, its internal energy was the same at the end as at the beginning of the experiment. The pressure and volume had changed, but the temperature had not. We must therefore conclude that the internal energy of a given mass of a gas depends only on its temperature, and not upon its pressure or volume; in other words, a change of pressure and volume not associated with a change of temperature does not alter the internal energy. Hence in any change of temperature the change of internal energy is independent of the relation of pressure to volume throughout the operation. Now we have seen above that the quantity

$$(K_p - c)(\tau_2 - \tau_1)$$

measures the gain of internal energy when 1 lb of a gas has its temperature changed from τ_1 to τ_2 in one particular way, namely, at constant pressure. Hence this same quantity also measures the gain of internal energy when 1 lb of a gas has its temperature changed from τ_1 to τ_2 in any manner whatsoever.

Relation of the two specific heats. 35. Next consider the case of 1 lb of a gas heated from τ_1 to τ_2 at constant volume. The heat taken in is

$$K_v(\tau_2 - \tau_1).$$

Since no work is done, this is all gain of internal energy, and is therefore (§ 34) equal to

$$(K_p - c)(\tau_2 - \tau_1).$$

Hence in any gas

$$K_p - c = K_v.$$

The ratio K_p/K_v will be denoted by γ; obviously $K_v = c/(\gamma - 1)$. The following table of values of K_p, K_v, c, and γ will be found useful in dealing with air and gas engines.

TABLE I.—*Properties of Gases.*

	K_p	K_v	c	γ
	Foot lbs.	Foot lbs.	Foot lbs.	
Dry air	183.4	130.2	53.2	1.409
Oxygen	167.9	119.8	48.1	1.402
Nitrogen	188.2	133.4	54.8	1.411
Hydrogen	2632	1864	768	1.412
Carbonic oxide	189.1	133.4	55.7	1.418
Carbonic acid	167.4	132.6	34.8	1.263
Marsh gas	457.7	363.1	94.6	1.261
Olefiant gas	311.9	257.7	54.2	1.213
Steam gas, or highly superheated steam	371	285.5	85.5	1.30

Work done in expansion. 36. We shall now return to the consideration of diagrams like that of § 25, which exhibit the action of a working substance by curves showing the relation of P to V during expansion or compression. In most of the instances which occur in the theory of heat engines such curves may be exactly or approximately represented by equations of the form

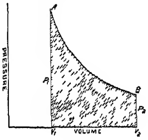

Fig. 10.

$$PV^n = \text{constant},$$

where the index n has various numerical values. Let AB, fig. 10, be a curve of expansion (of any substance) in which PV^n is constant, from pressure P_1 and volume V_1 at A to pressure P_2 and volume V_2 at B. We have, by assumption,

$$P_1V_1^n = P_2V_2^n.$$

The work done is

$$\int_{V_1}^{V_2} P\,dV = P_1V_1^n \int_{V_1}^{V_2} \frac{dV}{V^n} = \frac{P_1V_1^n(V_2^{1-n} - V_1^{1-n})}{1-n}.$$

This may also be written

$$\frac{P_1V_1(1 - r^{1-n})}{n-1},$$

where r is the ratio V_2/V_1, which may be called the ratio of expansion.

Still another form of the above expression for the work done is

$$\frac{P_1V_1 - P_2V_2}{n-1}.$$

37. Applying this result to the case of an expanding gas, we have

$$\text{Work done} = c(\tau_1 - \tau_2)/(n-1).$$

The loss of internal energy during expansion is, by § 34,

$$K_v(\tau_1 - \tau_2), \text{ or } c(\tau_1 - \tau_2)/(\gamma - 1), \text{ by § 35.}$$

Suppose now that the mode of expansion is such that the loss of internal energy is equal to the external work done, then

$$\frac{c(\tau_1 - \tau_2)}{n-1} = \frac{c(\tau_1 - \tau_2)}{\gamma - 1}, \text{ or } n = \gamma,$$

and the law of expansion is

$$PV^\gamma = \text{constant}.$$

The same formula applies when a gas is being compressed in such a manner that the work spent upon the gas is equal to the gain of internal energy by the gas.

Adiabatic expansion. 38. This mode of expansion (or compression) is termed *adiabatic*. It occurs when the working substance is neither gaining nor losing heat by conduction or radiation or internal chemical action. It would be realized if we had a substance expanding or being compressed, without chemical change, in a cylinder which (with the piston) was a perfect non conductor of heat. In adiabatic

expansion the external work is done entirely at the expense of the substance's stock of internal energy. Hence in the adiabatic expansion of a gas the temperature falls, and in adiabatic compression it rises. To find the change of temperature in a gas when expanded or compressed adiabatically we have only to combine the equations

$$P_1V_1^{\gamma}=P_2V_2^{\gamma} \text{ and } \frac{P_2V_2}{P_1V_1}=\frac{\tau_2}{\tau_1},$$

and we find

$$\tau_2=\tau_1\,(V_1/V_2)^{\gamma-1}$$

It is clear from the above that if, during expansion, n is less than γ the fluid is taking in heat, and if n is greater than γ the fluid is rejecting heat.

Isothermal expansion. 39. Another very important mode of expansion or compression is that called *isothermal*, in which the temperature of the working substance is kept constant during the process.

In the case of a gas the curve of isothermal expansion is a rectangular hyperbola, having the equation

$$PV=\text{constant}=c\tau$$

When a gas expands (or is compressed) isothermally at temperature τ from V_1 to V_2 the work done by (or upon) it (per lb) is

$$\int_{V_1}^{V_2}PdV=P_1\int_{V_1}^{V_2}\frac{dV}{V}=PV\log_\epsilon r=c\tau\log_\epsilon r\,,$$

where r is the ratio V_2/V_1 as before.[1]

During isothermal expansion or compression a gas suffers no change of internal energy (by § 34, since τ is constant). Hence during isothermal expansion a gas must take in an amount of heat just equal to the work it does, and during isothermal compression it must reject an amount of heat just equal to the work spent upon it. The expression $c\tau\log_\epsilon r$ consequently measures, not only the work done by or upon the gas, but also the heat taken in during isothermal expansion or given out during isothermal compression. In the diagram, fig 11, the line AB is an example of a curve of isothermal expansion for a perfect gas, called for brevity an isothermal line, while AC is an adiabatic line starting from the same point A.

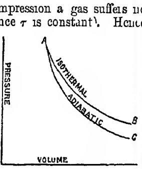

Fig 11

Carnot's cycle of operations. 40. We shall now consider the action of an ideal engine in which the working substance is a perfect gas, and is caused to pass through a cycle of changes each of which is either isothermal or adiabatic. The cycle to be described was first examined by Carnot, and is spoken of as Carnot's cycle of operations. Imagine a cylinder and piston composed of a perfectly non conducting material, except as regards the bottom of the cylinder, which is a conductor. Imagine also a hot body or indefinitely capacious source of heat A, kept always at a temperature τ_1, a perfectly non-conducting cover B, and a cold body or indefinitely capacious receiver of heat C, kept always at a temperature τ_2, which is lower than τ_1. It is supposed that A, B, or C can be applied to the bottom of the cylinder. Let the cylinder contain 1 lb of a perfect gas, at temperature τ_1, volume V_a, and pressure P_a to begin with. The suffixes refer to the points on the indicator diagram, fig 12.

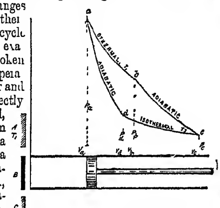

Fig 12.—Carnot's Cycle, with a gas for working substance

(1) Apply A, and allow the piston to rise. The gas expands isothermally at τ_1, taking heat from A and doing work. The pressure changes to P_b and the volume to V_b.

(2) Remove A and apply B. Allow the piston to go on rising. The gas expands adiabatically, doing work at the expense of its internal energy, and the temperature falls. Let this go on until the temperature is τ_2. The pressure is then P_c, and the volume V_c.

(3) Remove B and apply C. Force the piston down. The gas is compressed isothermally at τ_2, since the smallest increase of temperature above τ_2 causes heat to pass into C. Work is spent upon the gas, and heat is rejected to C. Let this be continued until a certain point d (fig 12) is reached, such that the fourth operation will complete the cycle.

(4) Remove C and apply B. Continue the compression, which is now adiabatic. The pressure and temperature rise, and if the point d has been properly chosen, when the pressure is restored to its original value P_a, the temperature will also have risen to its original value τ_1. [In other words, the third operation must be stopped when a point d is reached such that an adiabatic line drawn through d will pass through a.] This completes the cycle.

To find the proper place at which to stop the third operation, we have, by § 38, $\tau_1/\tau_2=(V_c/V_b)^{\gamma-1}$ in the second operation, and again $\tau_1/\tau_2=(V_d/V_a)^{\gamma-1}$ in the fourth operation. Hence $V_c/V_b=V_d/V_a$, and V_b/V_a, the ratio of isothermal expansion, is equal to V_c/V_d, the ratio of isothermal compression. For brevity we shall denote either of these last ratios by r.

41. The following are the transfers of heat to and from the working fluid, in successive stages of the cycle:—

(1) Heat taken in from $A=c\tau_1\log_\epsilon r$ (by § 39)

(2) No heat taken in or rejected

(3) Heat rejected to $C=c\tau_2\log_\epsilon r$ (by § 39)

(4) No heat taken in or rejected

Hence, by the first law of thermodynamics, the net external work done by the gas is

$$c(\tau_1-\tau_2)\log_\epsilon r\,,$$

and the efficiency of the engine (§ 23) is

$$\frac{c(\tau_1-\tau_2)\log_\epsilon r}{c\tau_1\log_\epsilon r}=\frac{\tau_1-\tau_2}{\tau_1}$$

This is the fraction of the whole heat given to it which an engine following Carnot's cycle converts into work. The engine takes in an amount of heat, at the temperature of the source, proportional to τ_1, it rejects an amount of heat, at the temperature of the receiver, proportional to τ_2. It works within a range of temperature extending from τ_1 to τ_2, by letting down heat from τ_1 to τ_2 (§ 24), and in the process it converts into work a fraction of that heat, which fraction will be greater the lower the temperature τ_2 at which heat is rejected is below the temperature τ_1 at which heat is received.

42. Next let us consider what will happen if we reverse Carnot's cycle, that is to say, if we force this engine to act so that the same indicator diagram as before is traced out, but in the direction opposite to that followed in § 40. Starting as before from the point a and with the gas at τ_1, we shall require the following four operations:— Carnot's cycle reversed.

(1) Apply B and allow the piston to rise. The gas expands adiabatically, the curve traced is ad, and when d is reached the temperature has fallen to τ_2.

(2) Remove B and apply C. Allow the piston to go on rising. The gas expands isothermally at τ_2, taking heat from C, and the curve dc is traced.

(3) Remove C and apply B. Compress the gas. The process is adiabatic. The curve traced is cb, and when b is reached the temperature has risen to τ_1.

(4) Remove B and apply A. Continue the compression, which is now isothermal, at τ_1. Heat is now rejected to A, and the cycle is completed by the curve ba.

In this process the engine is not doing work, on the contrary, work is spent upon it equal to the area of the diagram, or $c(\tau_1-\tau_2)\log_\epsilon r$. Heat is taken in from C in the first operation, to the amount $c\tau_2\log_\epsilon r$. Heat is rejected to A in the fourth operation, to the amount $c\tau_1\log_\epsilon r$. In the first and third operations there is no transfer of heat.

The action is now in every respect the reverse of what it was before. The same work is now spent upon the engine as was formerly done by it. The same amount of heat is now given to the hot body A as was formerly taken from it. The same amount of heat is now taken from the cold body C as was formerly given to it, as will be seen by the following scheme:—

Carnot's Cycle, Direct

Work done by the engine $=c(\tau_1-\tau_2)\log_\epsilon r$,

Heat taken from $A=c\tau_1\log_\epsilon r$,

Heat rejected to $C=c\tau_2\log_\epsilon r$

Carnot's Cycle, Reversed

Work spent upon the engine $=c(\tau_1-\tau_2)\log_\epsilon r$,

Heat rejected to $A=c\tau_1\log_\epsilon r$,

Heat taken from $C=c\tau_2\log_\epsilon r$

The reversal of the work has been accompanied by an exact reversal of each of the transfers of heat.

43. An engine in which this is possible is called, from the thermodynamic point of view, a *reversible* engine. In other words, a reversible heat engine is one which, if forced to trace out its indicator diagram reversed in direction, so that the work which would be done by the engine, when running direct, is actually spent upon it, will reject to the source of heat the same quantity of heat as, when running direct, it would take from the source, and will take from the receiver of heat the same quantity as, when running direct, it would reject to the receiver. By "the source of heat" is meant the hot body which acts as source, and by "the receiver" is meant the cold body which acts as receiver, when the Reversible engine.

[1] In calculations where this expression is involved it is convenient to remember that $\log_\epsilon$, the hyperbolic logarithm, of any number is 2.3026 times the common logarithm of the number.

engine is running direct. Carnot's engine is one example of a reversible engine. The idea of thermodynamic reversibility is highly important, for the reason that no heat engine can be more efficient than a reversible engine, if both take in and reject heat at the same pair of temperatures.

Reversibility the test of perfection in a heat engine.

44. To prove this, let it be supposed that we have two engines M and N, of which N is reversible in the above sense, and that we have a hot body A capable of acting as a source of heat, and a cold body C capable of acting as a receiver of heat. The engine M is set to work as a heat-engine, taking heat from A and rejecting heat to C. To prove that M cannot be more efficient than the reversible engine N, we shall assume that it is more efficient, and trace the consequences of that assumption.

Let M, working direct, be coupled so as to work N reversed, if we suppose that the engines are without mechanical friction, and can be coupled up without loss of power, the work represented by the indicator diagram of M is spent on N, and N will therefore reject to A an amount of heat which we will call Q_A and take from B an amount of heat which we will call Q_B. Now, since N is reversible, if it worked direct, taking Q_A from A, it would do the same amount of work as, in the supposed circumstances, is spent upon it. Hence, if M is more efficient than N it is taking from A an amount of heat *less* than Q_A, and consequently also is giving to B an amount of heat correspondingly less than Q_B. The joint effect, therefore, of M working direct and N working reversed is that the heat taken from A by M is less than the heat given to A by N, while the heat given to B by M is less (to an equal extent) than the heat taken from B by N. The consequence is that the hot body A is gaining heat on the whole, and the cold body B is losing an equal amount of heat; in other words, with the continued action of the double system heat passes, in indefinitely large quantity, from a cold body to a hot body, by means of an agency which, it is to be observed, is purely self acting, for if we suppose there is no mechanical friction the system requires no help from without. Now this result is, by the second law of thermodynamics (§ 23), contrary to all experience; and we are forced to conclude that the assumption that M is more efficient than the reversible engine N, when both take in and reject heat at the same two temperatures, is false. Hence, with given temperatures of source and receiver of heat no engine is more efficient than a reversible engine.

Next, let M and N both be reversible and both work between the same limits, but be different in any other respect. Then by the foregoing argument M cannot be more efficient than N, neither can N be more efficient than M. Hence all reversible heat engines taking in and rejecting heat at the same temperatures are equally efficient.

45. These results imply that reversibility, in the thermodynamic sense, is the criterion of what may be called perfection in a heat engine. A reversible engine is perfect in the sense that it cannot be improved on as regards efficiency: no other engine, taking in and rejecting heat at the same temperatures, will convert into work a greater fraction of the heat which it takes in. Moreover, if this criterion be satisfied, it is as regards efficiency a matter of complete indifference what is the nature of the working substance, or what, in other respects, is the mode of the engine's action.

Efficiency of a perfect heat-engine.

46. Further, since all engines that are reversible are equally efficient, provided they work between the same temperatures, an expression for the efficiency of one will apply equally to all. Now, the engine whose efficiency we have found in § 41 is one example of a reversible engine. Hence its efficiency

$$(\tau_1 - \tau_2) / \tau_1$$

is the efficiency of any reversible heat engine whatsoever taking in heat at τ_1 and rejecting heat at τ_2. And, as no engine can be more efficient than one that is reversible, this expression is the measure of *perfect efficiency*. We have thus arrived at the immensely important conclusion that no heat engine can convert into work a greater fraction of the heat which it receives than is expressed by the excess of the temperature of reception above that of rejection divided by the absolute temperature of reception.

Summary of the argument.

47. Briefly recapitulated, the steps of the argument by which this result has been reached are as follows. After stating the experimental laws to which gases conform, we examined the action of a heat engine in which the working substance took in heat when at the temperature of the source and rejected heat when at the temperature of the receiver, the change of temperature from one to the other of these limits being accomplished by adiabatic expansion and adiabatic compression. Taking a special case in which this engine had for its working substance a perfect gas, we found that its efficiency was $(\tau_1 - \tau_2)/\tau_1$ (§ 41). We also observed that it was, in the thermodynamic sense, a reversible engine (§ 43). Then we found, by an application of the second law of thermodynamics, that no heat engine can have a higher efficiency than a reversible engine, when taking in and giving out heat at the same two temperatures τ_1 and τ_2, this was shown by the fact that a contrary assumption leads to a violation of the second law (§ 44). Hence, we concluded that all reversible heat engines receiving and rejecting heat at the same temperatures τ_1 and τ_2 respectively are equally efficient, and hence that the efficiency $(\tau_1 - \tau_2)/\tau_1$, already determined for one particular reversible engine, measures the efficiency of any reversible engine, and is a limit of efficiency which no engine whatever can exceed.

Second law of thermodynamics.

48. The second law of thermodynamics, on which (along with the first law) this conclusion rests has been given in many different forms. The statement of it in § 23 is that of Clausius, and is very similar to that of Sir W. Thomson. Rankine, to whom with Thomson and Clausius is due the development of the theory of heat-engines from the point at which Carnot left it, has stated the second law in a form which is neither easy to understand, nor obvious, as an experimental result, when understood. His statement runs:—

"If the absolute temperature of any uniformly hot substance be divided into any number of equal parts, the effects of those parts in causing work to be performed are equal."[1]

To make this intelligible we may suppose that any quantity q of heat from a source at temperature τ_1 is taken by the first of a series of perfect heat engines, and that this engine rejects heat at a temperature τ_2 less than τ_1 by a certain interval $\Delta\tau$. Let the heat so rejected by the first engine form the heat supply of a second perfect engine working from τ_2 to τ_3 through an equal interval $\Delta\tau$, let the heat which it in turn rejects form the heat supply of a third perfect engine working again through an equal interval from τ_3 to τ_4, and so on. The efficiencies of the several engines are (by § 46) $\frac{\Delta\tau}{\tau_1}$, $\frac{\Delta\tau}{\tau_2}$, $\frac{\Delta\tau}{\tau_3}$, &c. The amounts of heat supplied to them are q, $q\frac{\tau_2}{\tau_1}$, $q\frac{\tau_3}{\tau_2}$, &c. Hence the amount of work done by each engine is the same, namely, $q\frac{\Delta\tau}{\tau_1}$. Thus Rankine's statement is to be understood as meaning that each of the equal intervals into which any range of temperature may be divided is equally effective in allowing work to be produced from heat when heat is made to pass, doing work in the most efficient possible way, through all the intervals from the top to the bottom of the range.

Thermodynamic absolute measurement of temperature.

49. A point of much theoretical interest may be noted in passing. In place of measuring temperature, as we have done, by the expansion of a perfect gas, a scale of temperature might be formed thus. Starting from any one temperature, let a series of intervals be taken such that a series of reversible engines, each working with one of the intervals for its range, in the manner described in § 48 (so that the heat rejected by the first forms the supply of the second, and so on), will each do the same amount of work; then *call these intervals equal*. This gives a scale of temperature (originally suggested by Sir W. Thomson) which is truly absolute in the sense of being independent of the properties of any substance; it coincides, as is evident from § 48, with the scale we have been using, in which equal intervals of temperature are defined as those corresponding to equal amounts of expansion of a perfect gas under constant pressure; and it coincides approximately with the scale of a mercury thermometer when that is graduated to read from the absolute zero by the addition of a suitable constant (§ 29).

Conditions of maximum efficiency.

50. The availability of heat for transformation into work depends essentially on the range of temperature through which the heat is let down from the hot source to the cold body into which heat is rejected; it is only in virtue of a difference of temperature between bodies that conversion of any part of their heat into work becomes possible. If τ_1 and τ_2 are the highest and lowest temperatures of the range through which a heat-engine works, it is clear that the maximum of efficiency can be reached only when the engine takes in all its heat at τ_1 and rejects at τ_2 all that is rejected. With respect to every portion of heat taken in and rejected the greatest ideal efficiency is

$$= \frac{\text{Temperature of reception} - \text{temperature of rejection}}{\text{Temperature of reception}}$$

Any heat taken in at a temperature below τ_1 or rejected at a temperature above τ_2 will have less availability for conversion into work than if taken in at τ_1 and rejected at τ_2, and hence, with a given pair of limiting temperatures, it is essential to maximum efficiency that no heat be taken in by the engine except at the top of the range, and no heat rejected except at the bottom of the range. Further, as we have seen in § 45, when the temperatures at which heat is received and rejected are assigned, an engine attains the maximum of efficiency if it be reversible.

Conditions of reversibility.

51. It is therefore important to inquire more particularly what kinds of action are reversible in the thermodynamic sense. A little consideration will show that a transfer of heat from the source or to the receiver is reversible only when the working substance is at sensibly the same temperature as the source or the receiver, as the case may be, and an expansion is reversible only when it occurs by the gradual displacement of some part of the containing envelope in such a manner that the expanding fluid does external work on the envelope, and does not waste energy to any sensible extent in setting itself in motion. This excludes what may be termed free expansion,

[1] *Manual of the Steam Engine and other Prime Movers*, § 243.

such as that of the gas in Joule's experiment, § 33, and it excludes also what may be called imperfectly-resisted expansion, such as would occur if the fluid were allowed to expand into a closed chamber in which the pressure was less than that of the fluid, or if the piston in a cylinder rose so fast as to cause, through the inertia of the expanding fluid, local variations of pressure throughout the cylinder

To make a heat engine, working within given limits of temperature, as efficient as possible we must therefore strive—(1) to take in no heat except at the highest temperature, and to reject no heat except at the lowest temperature, (2) to secure that the working substance shall, when receiving heat, be at the temperature of the body from which the heat comes, and that it shall, when giving up heat, be at the temperature of the body to which heat is given up, (3) to avoid free or imperfectly-resisted expansion If these conditions are fulfilled the engine is a perfect heat engine

Temperature of working substance changed by adiabatic expansion or compression

The first and second of these conditions are satisfied if in the action of the engine the working substance changes its temperature from τ_1 to τ_2 by adiabatic expansion, and from τ_2 to τ_1 by adiabatic compression, thereby being enabled to take in and reject heat at the ends of the range without taking in or rejecting any by the way This is the action in Carnot's engine (§ 40)

52 But if we can cause the working substance to deposit heat in some body within the engine while passing from τ_1 to τ_2, in such a manner that the transfer of heat from the substance to this body is reversible (satisfying the second condition above), then when we wish the working substance to pass from τ_2 to τ_1 we may reverse this transfer and so recover the heat that was deposited in this body

Regenerative principle

This alternate storing and restoring of heat may then take the place of adiabatic expansion and compression, in causing the temperature of the working substance to pass from τ_1 to τ_2 and from τ_2 to τ_1 respectively The alternate storing and restoring is an action occurring wholly within the engine, and is therefore distinct from the taking in and rejecting of heat by the engine

Stirling's regenerator

53 In 1827 Robert Stirling designed an apparatus, called a *regenerator*, by which this process of alternate storing and restoring of heat could be actually performed For the present purpose it will suffice to describe the regenerator as a passage through which the working fluid can travel in either direction, whose walls have a very large capacity for heat, so that the amount alternately given to or taken from them by the working fluid causes no more than an insensible rise or fall in their temperature The temperature of the walls at one end of the passage is τ_1, and this tapers continuously down to τ_2 at the other end When the working fluid at temperature τ_1 enters the hot end and passes through, it comes out at the cold end at temperature τ_2, having stored in the walls of the regenerator an amount of heat which it will pick up again when passed through in the opposite direction During the return journey its temperature rises from τ_2 to τ_1 The process is strictly reversible, or rather would be so if the regenerator had an unlimited capacity for heat, if no conduction of heat took place along its walls from the hot to the cold end, and if no loss took place by conduction or radiation from its external surface

Cycle in Stirling's engine

54 Using air as the working substance, and employing his regenerator, Stirling made an engine (to be described later) which, allowing for practical imperfections, is the earliest example of a truly reversible engine The cycle of operations in Stirling's engine is substantially this —

(1) Air (which has been heated to τ_1 by passing through the regenerator) is allowed to expand isothermally through a ratio r, taking in heat from a furnace and raising a piston Heat taken in (per lb of air) $= c\tau_1 \log_e r$

(2) The air is caused to pass through the regenerator from the hot to the cold end, depositing heat and having its temperature lowered to τ_2, without change of volume Heat stored in regenerator $= K_p(\tau_1 - \tau_2)$ The pressure of course falls

(3) The air is then compressed isothermally to its original volume at τ_2 in contact with a refrigerator (or receiver of heat) Heat rejected $= c\tau_2 \log_e r$

(4) The air is again passed through the regenerator from the cold to the hot end, taking up heat and having its temperature raised to τ_1 Heat restored by the regenerator $= K_p(\tau_1 - \tau_2)$

$$\text{Efficiency} = \frac{c\tau_1 \log_e r - c\tau_2 \log_e r}{c\tau_1 \log_e r} = \frac{\tau_1 - \tau_2}{\tau_1}$$

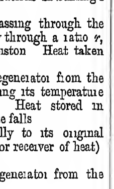

FIG 13 —Air Engine with Regenerator (Stirling)

The indicator diagram of the action is shown in fig 13, and a diagram of the engine is given in chap XIV Stirling's engine is important, not as a present day heat engine (though it has recently been revived in small forms after a long interval of disuse), but because it is typical of the only mode, other than Carnot's plan of adiabatic expansion and compression, by which the action of a heat engine can be made reversible Valuable as the regenerator has proved in metallurgy and other industrial processes, its actual application to heat-engines has hitherto been very limited An other way of using it in air-engines was designed by Ericsson, and attempts have been made by C W Siemens and F Jenkin to apply it to steam engines and to gas-engines But almost all actual engines, in so far as they can be said to approach the condition of reversibility, do so, not by the use of the regenerative principle, but by more or less nearly adiabatic expansion and compression after the manner of Carnot's ideal engine

III Properties of Steam and Theory of the Steam Engine

Formation of steam under constant pressure

55 We have now to consider the action of heat engines in which the working substance is water and water vapour or steam The properties of steam are most conveniently stated by referring in the first instance to what happens when steam is formed *under constant pressure* This is substantially the process which occurs in the boiler of a steam-engine when the engine is at work To fix the ideas we may suppose that the vessel in which steam is to be formed is a long upright cylinder fitted with a piston which may be loaded so that it exerts a constant pressure on the fluid below Let there be, to begin with, at the foot of the cylinder a quantity of water (which for convenience of numerical statement we shall take as 1 lb), at any temperature t_0, and let the piston press on the surface of the water with a force of P lb per square foot Let heat now be applied to the bottom of the cylinder As it enters the water it will produce the following effects in three stages —

(1) The temperature of the water rises until a certain temperature t is reached, at which steam begins to be formed The value of t depends on the particular pressure P which the piston exerts Until the temperature t is reached there is nothing but water below the piston

(2) Steam is formed, more heat being taken in The piston (which is supposed to exert a constant pressure) rises No further increase of temperature occurs during this stage, which continues until all the water is converted into steam During this stage the steam which is formed is said to be *saturated* The volume which the piston encloses at the end of this stage,—the volume, namely, of 1 lb of saturated steam at pressure P (and temperature t),—will be denoted by V in cubic feet

(3) If after all the water is converted into steam more heat be allowed to enter, the volume will increase and the temperature will rise The steam is then said to be *superheated*

Saturated and superheated steam

56 The difference between saturated and superheated steam may be expressed by saying that if water (at the temperature of the steam) be mixed with steam some of the water will be evaporated if the steam is superheated, but none if the steam is saturated Any vapour in contact with its liquid and in thermal equilibrium is necessarily saturated When saturated its properties differ considerably, as a rule, from those of a perfect gas, but when superheated they approach those of a perfect gas more and more closely the farther the process of superheating is carried, that is to say, the more the temperature is raised above t, the temperature of saturation corresponding to the given pressure P

Relation of pressure and temperature in saturated steam

57 The temperature t at which steam is formed depends on the value of P Their relation was determined with great care by Regnault, in a series of classical experiments on which our knowledge of the properties of steam chiefly depends [1] The pressure of saturated steam rises with the temperature at a rate which increases rapidly in the upper regions of the scale This will be apparent from the first and second columns of Table II, given on next page, which is compiled from Rankine's reduction of Regnault's results The first column gives the temperature on the Fahr scale, the second gives the corresponding pressure in pounds per square inch Rankine has also expressed the relation of temperature and pressure in saturated steam by the following formula (which is applicable with other constants to other vapours [2]) —

$$\log p = 6\ 1007 - \frac{2732}{\tau} - \frac{396945}{\tau^2},$$

where p is the pressure in pounds per square inch, and τ is the absolute temperature in Fahr degrees For most purposes, however, it is more convenient to find the pressure corresponding to a given temperature, or the temperature corresponding to a given pressure, from the table by interpolation

Relation of pressure and volume

58 The same table shows the volume V, in cubic feet, occupied by 1 lb of saturated steam at each pressure This is a quantity the direct experimental measurement of which is of very great difficulty It may, however, be calculated, from a knowledge of other properties of steam, by a process which will be described later (§ 75) The values of V given in the table were determined by Rankine by means of this process, they agree fairly well with such direct observations of the density of steam as have been hitherto

1 *Mem Inst France*, 1847, vol xxi An account of Regnault's methods of experiment and a statement of his results expressed in British measures will be found in Dixon's *Treatise on Heat*

2 *Phil Mag*, Dec 1854, or *Manual of the Steam Engine*, p 237.

made.[1] The relation of P to V may be approximately expressed by the formula[2]

$$PV^{\frac{17}{16}} = \text{constant} = 68500 \text{ (nearly)},$$

when P is stated in lb per sq. ft. and V in cub. ft. per lb.

Supply of heat in formation of steam under constant pressure.

59. We have next to consider the supply of heat. During the first stage, until the temperature rises from its initial value t_0 to t, the temperature at which steam begins to form under the given pressure, heat is required only to warm the water. Since the specific heat of water is nearly constant, the amount of heat taken in during the first stage is approximately $t-t_0$ thermal units or $J(t-t_0)$ foot-pounds, J being Joule's equivalent (§ 23), and this expression for it will generally serve with sufficient accuracy in practical calculations. More exactly, however, the heat taken in is somewhat greater than this, for Regnault's experiments show that the specific heat of water increases slightly as the temperature rises. In stating the amount of heat required for this first stage, t_0 must be taken as a known temperature; for convenience in numerical statement the temperature 32° F. is usually chosen as an arbitrary starting-point from which the reception of heat is to be reckoned. We shall employ the symbol h to designate the heat required to raise 1 lb of water from 32° F. to the temperature t at which steam begins to form. The value of h in thermal units is given, approximately, by the equation

$$h = t - 32.$$

More exact values, which take account of the variation in the specific heat of water, will be found in the last column of Table II. During the first stage, sensibly all the heat supplied goes to increase the stock of internal energy which the fluid possesses, the amount of external work which is done by the expansion of the fluid being negligible.

Latent heat.

60. The heat taken in during the second stage is what is called the *latent heat* of steam, and is denoted by L. Of it a part is spent in doing external work,—namely, P multiplied by the excess of the volume of the steam over the volume of the water,—and the remainder is the difference of internal energy between 1 lb of steam at t and 1 lb of water at t. The volume of 1 lb of water, at such temperatures as are usual in steam engines, is nearly 0.017 cubic feet. We may therefore write the external work (in foot-pounds) done during the production of 1 lb of steam under constant pressure P,—

$$\text{External work} = P(V - 0.017).$$

Total heat of steam.

61. Adding together the heat taken in during the first and second stages we have a quantity designated by H and called the *total heat* of 1 lb of saturated steam:—

$$H = h + L.$$

Regnault's values of H are very accurately expressed (in thermal units) by the formula

$$H = 1082 + 0.305t.$$

They are given in the fourth column of Table II. A similar formula gives approximate values of L, exact enough for use in practical calculations,—

$$L = 1114 - 0.7t.$$

The total heat of formation of 1 lb of steam, when formed under constant pressure from water at any temperature t_0, is of course $H - h_0$, where h_0 corresponds to t_0.

Internal energy.

62. Of the whole latent heat of steam, L, the part $P(V - 0.017)$ is, as has been said above, spent in doing external work. The energy remainder (in foot pounds)—

$$JL - P(V - 0.017)—$$

is the change of internal energy which the substance undergoes during evaporation. This quantity, for which it is convenient to have a separate symbol, will be denoted by ρ in thermal units, or $J\rho$ in foot-pounds. In dealing with the heat required to produce steam we adopted the state of water at 32° F. as an arbitrary starting-point from which to reckon the reception of heat. In the same way it is convenient to use this arbitrary starting point in reckoning what may be called the *internal energy* of the substance, which is the excess of the heat taken in over the external work done by the substance during its reception of heat. Thus the internal energy I of 1 lb of saturated steam at pressure P is equal to the total heat H, less that part of the total heat which is spent in doing external work, or (in foot pounds)

$$JI = JH - P(V - 0.017),$$

or

$$I = L + h - P(V - 0.017)/J = h + \rho.$$

The notion of internal energy is useful in calculating the heat taken in or rejected by steam during any stage of its expansion or compression in an engine. When a working substance passes from one condition to another, its gain or loss of heat is determined by the equation

Heat taken in = increase of internal energy + external work.

Any of the terms of this equation may be negative, the last term is negative when work is done, not by, but upon the substance.

Heat of formation under any conditions.

63. The same equation gives the means of finding the amount of heat required to form steam under any assigned conditions, in place of the condition assumed at the beginning of this chapter, where the formation of steam under constant pressure was considered. Whatever be the condition as to pressure under which the process of formation is carried on, the total heat required is the sum of the internal energy of the steam when formed and the work done by the substance during the process. Thus in general

$$\text{Heat of formation} = I + J^{-1}\int P\,dV,$$

the limits of integration being the final volume of the steam and the original volume of the water. When steam is formed in a closed vessel of constant volume no external work is done, the heat of formation is then equal to the internal energy, and is less than the total heat of formation (H) of steam, when formed at a constant pressure equal to the pressure reached in the vessel, by the quantity $P(V - 0.017)$.

Wet steam.

64. In calculations which relate to the action of steam in engines we have generally to deal, not with *dry* saturated steam, but with *wet* steam, or steam which either carries in suspension, or is otherwise mixed with, a greater or less proportion of water. In every such mixture the steam and water have the same temperature, and the steam is saturated. The dryness of wet steam is measured by the proportion q of dry steam in each pound of the mixed substance. When that is known it is easy to determine the other physical constants thus—

Latent heat of 1 lb of wet steam $= qL$,

Total heat of 1 lb of wet steam $= h + qL$,

Volume of 1 lb of wet steam $= qV + (1 - q)0.017$

$= qV$ very nearly,

unless the steam is so wet as to consist mainly of water,

Internal energy of 1 lb of wet steam $= h + q\rho$.

Super-heated steam.

65. Steam is superheated when its temperature is raised, in any manner, above the temperature corresponding to saturation at the actual pressure. When much superheated, steam behaves like a

[1] See Fairbairn and Tate, "On the Density of Steam at Different Temperatures," *Phil. Trans.*, vol. cl., 1860.

[2] This is Rankine's formula. Zeuner gives $PV^{1.0646}$ = constant.

perfect gas, and may be called "steam gas" It then follows the equation

$$PV = 85.5\tau,$$

and the specific heat at constant pressure, K_p, is 371 foot pounds or 0.48 thermal unit. At very low temperatures steam approximates closely to the condition of a perfect gas when very slightly superheated, and even when saturated, at high temperatures a much greater amount of superheating is necessary to bring about an approach to the perfectly gaseous state. The total heat required for the production of superheated steam under any constant pressure, when the superheating is sufficient to bring the steam to the state of steam gas, may therefore be reckoned by taking the total heat of saturated steam at a low temperature and adding to it the product of K_p into the excess of temperature above that. Thus Rankine, treating saturated steam at 32° F. as a gas, gives the formula

$$H' = 1092 + 0.48(t' - 32)$$

to express the heat of formation (under any constant pressure) of superheated steam, at any temperature t' which is so much above the temperature of saturation corresponding to the actual pressure that the steam may be treated as a perfect gas. Calculated from its chemical composition, the density of steam gas should be 0.622 times that of air at the same pressure and temperature. The value of γ or K_p/K_v for steam gas is 1.3. These formulas, dealing as they do with steam which is so highly superheated as to be perfectly gaseous, fail to apply to high pressure steam that is heated but little above its temperature of saturation. The relation of pressure to volume and temperature in the region which lies between the saturated and the perfectly gaseous states has been experimented on by Hirn.[1] Formulas which are applicable with more or less accuracy to steam in either the saturated or superheated condition have been devised by Hirn, Zeuner,[2] Ritter,[3] and others.

Isothermal expansion of steam

66. The expansion of volume which occurs during the conversion of water into steam under constant pressure—the second stage of the process described in § 55—is isothermal. From what has been already said it is obvious that steam, or any other saturated vapour, can be expanded or compressed isothermally only when wet, and that evaporation (in the one case) or condensation (in the other) must accompany the process. Isothermal lines for a working substance which consists of a liquid and its vapour are straight lines of uniform pressure.

Adiabatic expansion of steam

67. The form of adiabatic lines for substances of the same class depends not only on the particular fluid, but also on the proportion of liquid to vapour in the mixture. In the case of steam, it has been shown by Rankine and Clausius that if steam initially dry be allowed to expand adiabatically it becomes wet, and if initially wet (unless very wet[4]) it becomes wetter. A part of the steam is condensed by the process of adiabatic expansion, at first in the form of minute particles suspended throughout the mass. The temperature and pressure fall, and, as that part of the substance which remains uncondensed is saturated, the relation of pressure to temperature throughout the expansion is that which holds for saturated steam. The following formula, proved by Rankine[5] and Clausius[6] (see § 75), serves to calculate the extent to which condensation takes place during adiabatic expansion, and so allows the relation of pressure to volume to be determined.

Before expansion, let the initial dryness of the steam be q_1 and its absolute temperature τ_1. Then, if it expand adiabatically until its temperature falls to τ, its dryness after expansion is

$$q = \frac{\tau}{L}\left(\frac{q_1 L_1}{\tau_1} + \log_e \frac{\tau_1}{\tau}\right)$$

L_1 and L are the latent heats (in thermal units) of 1 lb of steam before and after expansion respectively. When the steam is dry to begin with, $q_1 = 1$.

This formula is easily applied to the construction of the adiabatic curve when the initial pressure and the pressure after expansion are given, the corresponding values τ and L being found from the table. It is less convenient if the data are the initial pressure and the initial and final volumes, or the initial pressure and the ratio of expansion r. An approximate formula more appropriate in that case is

$$Pv^n = \text{constant, or } P/P_1 = (v/v_1)^n = r^n$$

Here v and v_1 denote the volume of 1 lb of the mixture of steam and water before and after expansion respectively, and are to be distinguished from V and V_1, which we have already used to denote the volume of 1 lb of dry saturated steam at pressures P and P_1. The index n has a value which depends on the degree of initial dryness q_1.

According to Zeuner,[7] $n = 1.035 + 0.1q_1$, so that for

$q_1=$	1	0.95	0.9	0.85	0.8	0.75	0.7
$n=$	1.135	1.130	1.125	1.120	1.115	1.110	1.105

Rankine gave for this index the value $\frac{10}{9}$, which is too small if the steam be initially dry. He determined it by examining the expansion curves of indicator diagrams taken from working steam engines, but, as we shall see later, the expansion of steam in an actual engine is by no means adiabatic, on account of the transfer of heat which goes on between the working fluid and the metal of the cylinder and piston. When it is desired to draw an adiabatic curve for steam, that value of n must be chosen which refers to the degree of dryness at the beginning of the expansion.

68. We are now in a position to study the action of a heat engine employing steam as the working substance. To simplify the first cycle with consideration as far as possible, let it be supposed that we have, as before, a long cylinder composed of non conducting material except at the base, and fitted with a non conducting piston, also a source of heat A at some temperature τ_1, a receiver of heat, or, as we may now call it, a condenser C, at a lower temperature τ_2, and a non conducting cover B (as in § 40). Then we can perform Carnot's cycle of operations as follows. To fix the ideas, suppose that there is 1 lb of water in the cylinder to begin with, at the temperature τ_1 —

Carnot's cycle with steam for substance

(1) Apply A and allow the piston to rise. The water will take in heat and be converted into steam, expanding isothermally at constant pressure P_1. This part of the operation is shown by the line ab in fig 14.

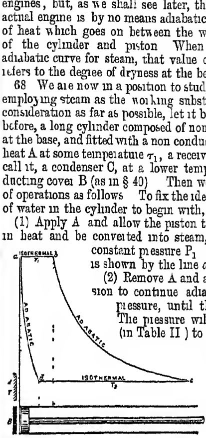

FIG 14.—Carnot's Cycle with water and steam for working substance.

(2) Remove A and apply B. Allow the expansion to continue adiabatically (bc), with falling pressure, until the temperature falls to τ_2. The pressure will then be P_2, corresponding (in Table II.) to τ_2.

(3) Remove B, apply C, and compress. Steam is condensed by rejecting heat to C. The action is isothermal, and the pressure remains P_2. Let this be continued until a certain point d is reached, after which adiabatic compression will complete the cycle.

(4) Remove C and apply B. Continue the compression, which is now adiabatic. If the point d has been rightly chosen, this will complete the cycle by restoring the working fluid to the state of water at temperature τ_1.

The indicator diagram for the cycle is given in fig 14, as calculated by the help of the equations in § 67 and of Table II. for a particular example, in which $p_1 = 90$ lb per square inch ($\tau_1 = 781$), and the expansion is continued down to the pressure of the atmosphere, 14.7 lb per square inch ($\tau_2 = 673$). Since the process is reversible, and since heat is taken in only at τ_1 and rejected only at τ_2, the efficiency is $(\tau_1 - \tau_2)/\tau_2$. The heat taken in per lb of the fluid is L_1, and the work done is $L_1(\tau_1 - \tau_2)/\tau_1$, a result which may be used to check the calculation of the diagram.

Efficiency of a perfect steam-engine

69. If the action here described could be realized in practice, we should have a thermodynamically perfect steam engine using saturated steam. The fraction of the heat supplied to it which such an engine would convert into work would depend simply on the temperature, and therefore on the pressure, at which the steam was produced and condensed. The temperature of condensation is limited by the consideration that there must be an abundant supply of some substance to absorb the rejected heat, water is actually used for this purpose, so that τ_2 has for its lower limit the temperature of the available water supply.

Limits of temperature

To the higher temperature τ_1 and pressure P_1 no limit can be set except such as is brought about in practice by the mechanical difficulties, with regard to strength and to lubrication, which attend the use of high-pressure steam. By a very special construction of engine and boiler Mr Perkins has been able to use steam with a pressure as high as 500 lb per square inch, with engines of the usual construction the value ranges from 190 lb downwards.

If the temperature of condensation be taken as 60° F., as a lower limit, the efficiency of a perfect steam-engine, using saturated steam, would depend on the value of P_1, the absolute pressure of production of the steam, as follows —

For perfect steam engine, with condensation at 60° F.,

P_1 in lb per square inch being	40	80	120	160	200
Highest ideal efficiency =	.284	.326	.350	.368	.381

But it must not be supposed that these values of the efficiency are actually attained, or are even attainable. Many causes conspire to prevent steam engines from being thermodynamically perfect, and some of the causes of imperfection cannot be removed. These numbers will serve, however, as a standard of comparison in judging of

[1] *Théorie Mécanique de la Chaleur*

[3] *Wied. Ann.*, 1878. For a discussion of several of these formulas, see a paper by H. Dyer, *Trans. Inst. of Engineers and Shipbuilders in Scotland*, 1885.

[4] Prof. Cotterill, in his *Treatise on the Steam-Engine*, § 79, has calculated (using the equation which follows in the text) that, when a mixture of steam and water expands adiabatically, steam condenses if the proportion of steam be, roughly, over 50 per cent, but water is evaporated if the proportion of steam be less than about 50 per cent. The exact proportion depends on the initial pressure.

the performance of actual engines, and as setting forth the advantage of high pressure steam from the thermodynamic point of view

Efficiency of an engine using steam non-expansively 70 As a contrast to the ideally perfect steam-engine of § 68 we may next consider a cyclic action such as occurred in the early engines of Newcomen or Leupold, when steam was used non expansively,—or rather, such an action as would have occurred in engines of this type had the cylinder been a perfect non conductor of heat Let the cycle of operations be this —

(1) Apply A and evaporate the water as before at P_1 Heat taken in $=L_1$

(2) Remove A and apply C This at once condenses a part of the steam, and reduces the pressure to P_2

(3) Compress at P_2, in contact with C, till condensation is complete, and water at τ_2 is left

(4) Remove B and apply A This heats the water again to τ_1 and completes the cycle Heat taken in $=h_1-h_2$

The indicator diagram for this series of operations is shown in fig 15

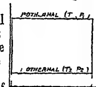

Fig 15

Here the action is not reversible To calculate the efficiency, we have

$$\frac{\text{Work done}}{\text{Heat taken in}}=\frac{(P_1-P_2)(V_1-0.017)}{J(L_1+h_1-h_2)}$$

The values of this will be found to range from 0.067 to 0.072 for the values of P_1 which are stated in § 69, when the temperature of condensation is 60° F

Engine with separate organs 71 In the ideal engine represented in fig 14 the functions of boiler, cylinder, and condenser are combined in a single vessel, but after what has been said in chap II it is scarcely necessary to remark that, provided the working substance passes through the same cycle of operations, it is indifferent whether these are performed in several vessels or in one To approach a little more closely the conditions that hold in practice, we may think of the engine which performs the cycle of § 70 as consisting of a boiler A (fig 16) kept at τ_1, a non conducting cylinder and piston B, a surface condenser C kept at τ_2, and a feed-pump D which restores the condensed water to the boiler Then for every pound of steam supplied and used non expansively as in § 70, we have work done on the piston $=(P_1-P_2)V_1$, but an amount of work has to be expended in driving the feed-pump $=(P_1-P_2)\,0.017$ Deducting this, the net work done per lb of steam is the same as before, and the heat taken in is also the same

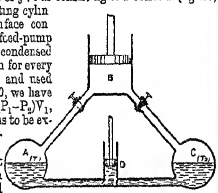

Fig 16—Organs of a Steam Engine

An indicator diagram taken from the cylinder would give the area $efgh$ (fig 17), where $oe=P_1$, $ef=V_1$, $oh=P_2$, an indicator diagram taken from the pump would give the negative area $hgie$, where ei is the volume of the feed water, or 0.017 cub ft The difference, namely, the shaded area, is the diagram of the complete cycle gone through by each pound of the working substance In experimental measurements of the work done in steam engines, only the action which occurs within the cylinder is shown on the indicator diagram From this the work spent on the feed-pump is to be subtracted in any accurate determination of the thermodynamic efficiency If the feed-water is at any temperature τ_0 other than that of the condenser as assumed in § 70, it is clear that the heat taken in is H_1-h_0 instead of H_1-h_2

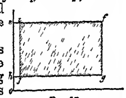

Fig 17

How nearly may the process be reversible? 72 We have now to inquire how nearly, with the engine of fig 16 (that is to say, with an engine in which the boiler and condenser are separate from the cylinder), we can approach the reversible cycle of § 68 The first stage of that cycle corresponds to the *admission* of steam from the boiler into the cylinder Then the point known as the point of *cut-off* is reached, at which admission ceases, and the steam already in the cylinder is allowed to expand, exerting a diminishing pressure on the piston This is the second stage, or the stage of *expansion* The process of expansion may be carried on until the pressure falls to that of the condenser, in which case the expansion is said to be complete At the end of the expansion *release* takes place, that is to say, communication is opened with the condenser Then the return stroke begins, and a period termed the *exhaust* occurs, that is to say, steam passes out of the cylinder, into the condenser, where it is condensed at pressure P_2, which is felt as a *back pressure* opposing the return of the piston So far, all has been essentially reversible, and identical with the corresponding parts of Carnot's cycle

But we cannot complete the cycle as Carnot's cycle was completed The existence of a separate condenser makes the fourth stage, that of adiabatic compression, impracticable, and the best we can do is to continue the exhaust until condensation is complete, and then return the condensed water to the boiler by means of the feed pump

It is true that we may, and in actual practice do, stop the exhaust before the return stroke is complete, and compress that portion of the steam which remains below the piston, but this does not materially affect the thermodynamic efficiency, it is done partly for mechanical reasons, and partly to avoid loss of power through clearance (see chap IV) In the present instance it is supposed that there is no clearance, in which case this compression is out of the question The indicator diagram given by a cylinder in which steam goes through the action described above is shown to scale in fig 18 for a particular example, in which it is supposed that 1 cubic foot of dry saturated steam is admitted at an absolute pressure of 90 lb per square inch, and is expanded twelve times, or down to a pressure of 5.4 lb per square inch, at which pressure it is discharged to the condenser

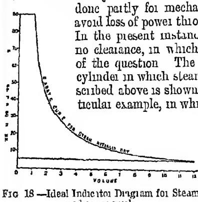

Fig 18—Ideal Indicator Diagram for Steam used expansively

As we have assumed the cylinder to be non conducting, and the steam to be initially dry, the expansion follows the law $PV^{1.135}=$ constant The advantage of expansion is obvious, that part of the diagram which lies under the curve being so much clear gain

Efficiency of engine working expansively 73 To calculate the efficiency, we have

Work done per lb during admission $=P_1V_1$,

" " during expansion to volume $rV_1=\dfrac{P_1V_1-P_2rV_1}{n-1}$,

(by § 36), $=(P_1V_1-P_2rV_1)/0.135$,

Work spent during return stroke $=P_2rV_1$,

" " on the feed pump $=(P_1-P_2)\,0.017$,

Heat taken in $=H_1-h_0$

Incomplete expansion 74 These expressions refer to complete expansion When the expansion is incomplete, as it generally is, the expression given above for the work done during expansion still applies if we take P_2 to be the pressure at the end of expansion, while the work spent on the steam during the back stroke is $P_b rV_1$ and that spent on the feed pump is $(P_1-P_b)\,0.017$, P_b being the back pressure Incomplete expansion is illustrated by the dotted line in fig 18

It is easy, by the aid of §§ 64 and 67 to extend these calculations to cases where the steam, instead of being initially dry, is supposed to have any assigned degree of wetness The efficiency which is calculated in this way, which for the present purpose may be called the theoretical efficiency corresponding to the assumed conditions of working, is always much less than the ideal efficiency of a perfect engine, since the cycle we are now dealing with is not reversible But even this theoretical efficiency, short as it falls of the ideal of a perfect engine, is far greater than can be realized in practice when the same boiler and condenser temperatures are used, and the same ratio of expansion The reasons for this will be briefly considered in the next chapter, at present the fact is mentioned to guard the reader from supposing that the results which the above formulas give apply to actual engines

Calculation of density of saturated steam 75 The results of § 68 have been turned to account by Rankine and Clausius for the purpose of deducing the density of steam from other properties which admit of more exact direct measurement Let the perfect steam-engine there described work through a very small interval of temperature $\Delta\tau$ between two temperatures τ and $\tau-\Delta\tau$ The efficiency is $\Delta\tau/\tau$, and the work done (in foot-lbs) is $JL\Delta\tau/\tau$ The indicator diagram is now reduced to a long narrow strip, whose length is $V-0.017$ and its breadth ΔP, the difference in pressure between steam at temperatures τ and $\tau-\Delta\tau$ Hence the work done is also $\Delta P(V-0.017)$, and therefore

$$V-0.017=\frac{JL}{\tau}\,\frac{\Delta\tau}{\Delta P}$$

Here $\dfrac{\Delta\tau}{\Delta P}$, or (in the limit) $\dfrac{d\tau}{dP}$, is the rate of increase of temperature with increase of pressure in saturated steam at the particular temperature τ It may be found roughly from Table II, p 484, or more exactly by differentiating the equation given in § 57 L is also known, and hence the value of V corresponding to any assigned temperature may be calculated with a degree of accuracy which it would be difficult to reach in direct experiment The volumes given in the Table are determined in this way [1]

[1] The result of § 75 may be applied as follows to give the formula of § 67 for the adiabatic expansion of wet steam For brevity we may write $V-0.017=u$. In adiabatic expansion the work done is equal to the loss of internal energy, or

$$Pd(qu)=-JdI=-Jd(h+q\rho)$$

Since $dh=d\tau$, and $\rho=L-Pu/J$, this may be written $Jd\tau+Jd(qL)-qudP=0$

By § 75, $udP=\dfrac{JL}{\tau}d\tau$, hence $1+\dfrac{d}{d\tau}(qL)-\dfrac{qL}{\tau}=0$,

and by integration,

$$\log_e\tau+qL/\tau=\text{constant}=\log_e\tau_1+q_1L_1/\tau_1,$$

which is the equation of § 67

IV ACTUAL BEHAVIOUR OF STEAM IN THE CYLINDER

Actual indicator diagram — 76 In fig 18 we have what may be called a first approximation to the theoretical indicator diagram of a steam engine In the action then described it was assumed—(1) that the steam supplied was dry and saturated, and had during admission the full (uniform) pressure of the boiler P_1, (2) that there was no transfer of heat to or from the steam except in the boiler and in the condenser, (3) that after more or less complete expansion all the steam was discharged by the return stroke of the piston, during which the back pressure was the (uniform) pressure in the condenser P_2, (4) that the whole volume of the cylinder was swept through by the piston It remains to be seen how far these assumptions are untrue in practice, and how far the efficiency is affected in consequence

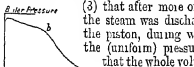

FIG 19 —Actual Indicator Diagram from a Condensing Steam-Engine

The actual conditions of working differ from these in the following main respects, some of which are illustrated by the practical indicator diagram of fig 19, which is taken from an actual engine

Wire drawing — 77 Owing to the resistance of the ports and passages, and to the inertia of the steam, the pressure within the cylinder is less than P_1 during admission and greater than P_2 during exhaust Moreover P_1 and P_2 are themselves not absolutely uniform, and P_2 is greater than the pressure of steam at the temperature of the condenser, on account of the presence of air in the condenser

During admission the pressure of steam in the cylinder is less than the boiler pressure by an amount which increases as the piston advances, on account of the increased velocity of the piston's motion and the consequent increased demand for steam When the ports and passages offer much resistance the steam is expressively said to be throttled or "wire-drawn" Wire drawing of steam is in fact a case of imperfectly resisted expansion (§ 51) The steam is dried by the process to a small extent, and if initially dry it becomes superheated In an indicator diagram wire drawing causes the line of admission to lie below a line drawn at the boiler pressure, and to slope downwards In fairly good practical instances the mean absolute pressure during admission is about nine tenths of the pressure in the boiler

In the same way, during the exhaust the actual back pressure exceeds the pressure in the condenser (shown by a dotted line in fig 19) by an amount depending on the freedom with which the steam makes its exit from the cylinder In condensing engines with a good vacuum the actual back pressure is from 3 to 5 lb per square inch, and in non condensing engines it is 16 to 18 lb in place of the mere 14 7 lb which is the pressure of the atmosphere The excess of back pressure may be greatly increased by the presence of water in the cylinder The effects of wire drawing do not stop here The valves open and close more or less slowly, the points of cut-off and release are therefore not absolutely sharp, and the diagram has rounded corners at *b* and *c* in place of the sharp angles which mark those events in fig 18 For this reason release is allowed in practice to occur a little before the end of the forward stroke, hence the toe of the diagram takes a form like that shown in fig 19 The sharpness of the cut-off, and to a less extent the sharpness of the release, depends greatly on the kind of valves and valve gear used, valves of the Corliss type (to be described later), which are noted for the suddenness with which admission of steam is stopped, have the merit amongst others of producing a very sharply defined diagram

Clearance — 78 When the piston is at either end of its stroke there is a small space left between it and the cylinder cover This space, together with the volume of the passage or passages leading thence to the steam and exhaust valves, is called the *clearance* It constitutes a volume through which the piston does not sweep, but which is nevertheless filled with steam when admission occurs, and the steam in the clearance forms a part of the whole steam which expands after the supply from the boiler is cut-off If AC be the volume swept through by the piston up to release, OA the volume of the clearance, and AB the volume swept through during admission, the apparent ratio of expansion is AC/AB, but the real ratio is (OA + AC)/(OA + AB)

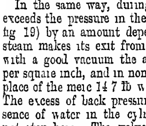

FIG 20 —Effect of Clearance

Clearance must obviously be taken account of in any calculation of curves of expansion It is conveniently allowed for in indicator diagrams by shifting the line of no volume back through a distance corresponding to the clearance (fig 20) In actual engines OA is from $\frac{1}{10}$ to $\frac{1}{50}$ of the volume of the cylinder

79 Clearance affects the thermodynamic efficiency of the engine chiefly by altering the consumption of steam per stroke, and its influence depends materially on the *compression* (§ 72) If during the back stroke the process of exhaust is discontinued before the end, the remaining steam is compressed, this cushion of steam will finally fill the volume of the clearance, and by a proper selection of the point at which compression begins the pressure of the cushion may be made to rise just up to the pressure at which steam is admitted when the valve opens This may be called complete compression, and when it occurs the existence of clearance has no direct effect on the consumption of steam nor on the efficiency, the whole fluid in the cylinder may then be thought of as consisting of two parts,—a permanent cushion which is alternately expanded and compressed without net gain or loss of work, and the working part proper, which on admission fills the volume AB (fig 20), and which enters and leaves the cylinder in each stroke But if compression be incomplete or absent there is, on the opening of the admission valve, an inrush of steam to fill up the clearance space This increases the consumption to an extent which is only partly counterbalanced by the increased area of the diagram, and the result is that the efficiency is reduced The action is, in fact, a case of unresisted expansion (§ 51), and consequently tends, so far as its direct effects go, to make the engine less than ever reversible It is to be noted, however, that by such unresisted expansion the entering steam is dried to some extent, and this helps in a measure to counteract the cause of loss which will be described below Compression has the mechanical advantage that it obviates the shock which the admission of steam would otherwise cause, and that by giving the piston work to do while its velocity is being rapidly reduced it reduces those stresses in the mechanism which are due to the inertia of the reciprocating parts — Compression and cushioning

80 The third and generally by far the most important element of difference between the action of a real engine and that of our hypothetical engine is that alluded to at the end of chap I, the difference which proceeds from the fact that the cylinder and piston walls are not non-conductors As the steam fluctuates in temperature there is a complex give and-take of heat between it and the metal it touches, and the effects of this, though not very conspicuous on the indicator diagram, have an enormous influence in reducing the efficiency by increasing the consumption of steam Attention was drawn to this action by Mr D K Clark as early as 1855 (*Railway Machinery*, or art STEAM ENGINE, *Ency Brit*, 8th edition[1]), and the results of his experiments on locomotives were confirmed some years later by Mr Isherwood's trials of the engines of the United States steamer "Michigan" Rankine in his classical work on the steam engine notices the subject only very briefly, and takes no account of the action of the cylinder walls in his calculations Its importance has now been established beyond dispute, notably by the experiments of Messrs Loring and Emery on the engines of certain revenue steamers of the United States,[2] and by a protracted series of investigations carried out by M Hallauer and other Alsatian engineers under the direction of Hirn,[3] whose name should be specially associated with the rational analysis of engine tests In the next chapter some account will be given of how steam-engines are experimentally examined and how (following Hirn) we may deduce the exchanges of heat which occur between the steam and the cylinder throughout the stroke The following is, in general terms, what experiments with actual engines show to take place — Influence of cylinder walls

81 When steam is admitted at the beginning of the stroke, it finds the metallic surfaces of the cylinder and piston chilled by having been in contact with low pressure steam during the exhaust of the previous stroke A portion of it is therefore liquefied, and, as the piston advances, more and more of the chilled cylinder surface is exposed and more and more of the hot steam is condensed At the end of the admission, when communication with the boiler is cut off, the cylinder consequently contains a film of water spread over the exposed surface, in addition to saturated steam The boiler has therefore been drawn upon for a supply greater than that corresponding to the volume of steam in the admission space The importance of this will be obvious from the fact, demonstrated by experiment, that the steam which is thus condensed during admission frequently amounts to 30 and even 50 per cent of the whole quantity that comes over from the boiler — Initial condensation

82 Then, as expansion begins, more cold metal is uncovered, and some of the remaining steam is condensed upon it But the pressure of the steam now falls, and the layer of water which has been previously deposited begins to be re evaporated as soon as the temperature of the expanding steam falls below that of the liquid layer On the whole, then, the amount of water present will increase during the earliest part of the expansion, but a stage will soon be reached when the condensation which occurs on the newly exposed metal is balanced by re evaporation of older portions of the layer The percentage of water present is then a maximum, and from this point onwards the steam becomes more and more dried by re evaporation of the layer — Re evaporation

83 If the amount of initial condensation has been small this

[1] See also *Min Proc Inst C E*, vol lxxii p 275

[2] A useful abstract of Messrs Loring and Emery's reports is given in *Engineering*, vols xix and xxi, and in Mr Maw's *Recent Practice in Marine Engineering*

[3] *Bull Soc Industr de Mulhouse*, from 1877 For other references, see chap V

re-evaporation may be complete before release occurs. Very usually, however, there is still an undried layer at the end of the forward stroke, and the process of re-evaporation continues during the return stroke, while exhaust is taking place. In extreme cases, if the amount of initial condensation has been very great, the cylinder walls may fail to become quite dry even during the exhaust, and a residue of the layer of condensed water may either be carried over as water into the condenser, or, if the exhaust valves are so badly arranged as to prevent its discharge, this unevaporated residue may gather in the cylinder, requiring perhaps the drain cocks to be left open to allow of its escape. When any water is retained in this way the initial condensation is enormously increased, for the hot steam then meets not only cold metal but cold water. The latter causes much condensation, partly because of its high specific heat, and partly because it is brought into intimate mixture with the entering steam.

Cooling effect of re-evaporation. 84. Apart, however, from this extreme case, whatever water is re-evaporated during expansion and exhaust takes heat from the metal of the cylinder, and so brings it into a state that makes condensation inevitable when steam is next admitted from the boiler. Mere contact with low-pressure steam during the exhaust stroke would cool the metal but little; the cooling which actually occurs is due mainly to the re-evaporation of the condensed water. Thus if an engine were set in action, after being heated beforehand to the boiler temperature, the cylinder would be only slightly cooled during the first exhaust stroke, and little condensation would occur during the next admission. But the metal would be more cooled in the subsequent expansion and exhaust, since it would part with heat in re-evaporating this water. In the third admission more still would be condensed, and so on, until a permanent régime would be established in which condensation and re-evaporation were exactly balanced. The same permanent regime is reached when the engine starts cold.

Wetness of steam during expansion. 85. The wetness of the working fluid to which the action of the walls of the cylinder gives rise is essentially superficial. A film of water forms on the walls, but except for this the body of the steam remains dry, until (by adiabatic or nearly adiabatic expansion) it becomes wet throughout its volume. The water formed by the act of expansion takes form as a mist diffused throughout the steam, and on it the sides of the cylinder exert practically no influence. This latter wetness is in fact increasing while the substance, as a whole, is getting dried by the re-evaporation of the liquid film. During expansion the working substance may be regarded as made up of two parts,—a core of steam, which is expanding adiabatically but is at the same time receiving additions to its amount in the form of saturated steam from the liquid layer, and a liquid layer which is turning into steam.

Waste of heat. 86. From a thermodynamic point of view all initial condensation of the steam is bad, for, however early the film be re-evaporated, this can take place only after its temperature has cooled below that of the boiler. The process consequently involves a misapplication of heat, since the substance, after parting with high-temperature heat, takes it up again at a temperature lower than the top of its range. This causes a loss of efficiency (chap. II.), and the loss is greater the later in the stroke re-evaporation occurs. The heat that is drawn from the cylinder by re-evaporation of the condensed film becomes less and less effective for doing work as the end of the expansion is approached, and, finally, whatever evaporation continues during the back stroke is an unmitigated source of waste. The heat it takes from the cylinder does no work; its only effect, indeed, is to increase the back pressure by augmenting the volume of steam to be expelled. A small amount of initial condensation reduces the efficiency of the engine but little; a large amount causes a much more than proportionally larger loss.

Effect of jacket. 87. The action of the cylinder walls is increased by any loss of heat which the engine suffers by radiation and conduction from its external surface. The entering steam has then to give up enough heat to provide for this waste, as well as enough to produce the subsequent re-evaporation of the condensed film. The consequence is that more steam is initially condensed. The loss of efficiency due to this cause will therefore be greater in an unprotected cylinder than in one which is well lagged or covered with non-conducting material. On the other hand, if the engine have a steam-jacket the deleterious action of the walls is reduced. The working substance is then on the whole gaining instead of losing heat by conduction during its passage through the cylinder. The jacket accelerates the process of re-evaporation and tends to make it finish at a point in the stroke when the temperature of the steam is still comparatively high. When the process is complete the cylinder walls give up very little additional heat to the steam during the remainder of the expansion and exhaust, for conduction and radiation between dry steam and the metal of the cylinder are incompetent to cause any considerable exchange of heat. The earlier, therefore, that evaporation is complete the less is the metal chilled, and the less is the subsequent condensation. Moreover, after this stage in the stroke has passed, a steam-jacket continues to give heat to the metal during the remainder of the double stroke, and so warms it to a temperature more nearly equal to that of the boiler steam before the next admission takes place.

88. Thus a steam-jacket, though in itself a thermodynamically imperfect contrivance, inasmuch as its object is to supply heat to the working substance at a temperature lower than the source, acts beneficially by counteracting, to some extent, the more serious misapplication of heat which occurs through the alternate cooling and heating of the cylinder walls. The heat which a jacket communicates to working steam often increases the power of an engine to an extent far greater than corresponds to the extra supply of heat which the jacket itself requires. Besides its thermodynamic effect a jacket has the drawback that it increases waste by external radiation, since it both enlarges the area of radiating surface and raises its temperature; notwithstanding this, however, many experiments have shown that in large and especially in slow-running engines, the influence of a steam-jacket on the efficiency is, in general, good, and this is to be ascribed to the fact that it reduces, though it does not entirely remove, the evils of initial condensation. To be effective, however, jackets must be well drained and kept full of "live" steam, instead of being, as many are, traps for condensed water or for air.

89. It is interesting to notice, in general terms, the effects which certain variations of the conditions of working may be expected to produce on the loss that occurs through the action of the cylinder walls. Initial condensation will be increased by anything that augments the range of temperature through which the inner surface of the cylinder fluctuates in each stroke, or that exposes a larger surface of metal to the action of a given quantity of steam, or that prolongs the contacts in which heat is exchanged. The influence of time is specially important, for it must be borne in mind that the whole action depends on the rate at which heat is conducted into the substance of the metal. **Influence of speed.** The changes of temperature which the metal undergoes are in every case mainly superficial; the alternate heating and cooling of the inner surface initiates waves of high and low temperature in the iron whose effects are sensible only to a small depth; and the faster the alternate states succeed each other the more superficial are the effects. In an engine making an indefinitely large number of strokes per minute the cylinder sides would behave like non-conductors and the action of the working substance would be adiabatic.

We may conclude, then, that in general an engine running at a high speed will have a higher thermodynamic efficiency than the same engine running at a low speed, all the other conditions of working being the same in both cases.

Again, as regards range of temperature, the influence of the cylinder walls will be greater (other things being equal) with high than with low pressure steam, and in condensing than in non-condensing engines. On the other hand, high pressure has the good effect of reducing the surface of metal exposed to the action of each pound of steam.

In large engines the action of the walls will be less than in small engines, since the proportion of wall surface to cylinder volume is less. **Influence of size.** This conclusion agrees with the well-known fact that no small engines achieve the economy that is easily reached with larger forms, especially with large marine engines, which eclipse all others in the matter of size.

Cylinder condensation is increased when the ratio of expansion is increased, all the other circumstances of working being left unaltered. **Influence of variation in** The metal is then brought into more prolonged contact with low-temperature steam. The volume of admission is cut off reduced to a greater extent than the surface that is exposed to the entering steam, since that surface includes two constant quantities, the surface of the cylinder cover and of the piston. For these and perhaps other reasons, we may conclude that with an early cut-off the initial condensation is relatively large; and this conclusion is amply borne out by experiment. An important result is that increase of expansion does not, beyond a certain limit, involve increase of thermodynamic efficiency; when that limit is passed the augmentation of waste through the action of the cylinder walls more than balances the increased economy to which, on general principles, expansion should give rise, and the result is a net loss. With a given engine, boiler pressure, and speed, a certain ratio of expansion will give maximum efficiency. But the conditions on which this maximum depends are too complex to admit of theoretical solution; the best ratio can be determined only by experiment. It may even happen that an engine which is required to work at a specified power will give better results, in point of efficiency, with moderate steam pressure and moderate expansion, than with high steam pressure and a very early cut-off.

Experimental results. 90. The effect of increased expansion in augmenting the action of the sides and so reducing the efficiency, when carried beyond a certain moderate grade, is well illustrated by the American and Alsatian experiments alluded to above. The following figures (Table III.), relating to a single cylinder Corliss engine, are reduced from one of Hallauer's papers.[1]—

[1] *Bull. Soc. Industr. de Mulhouse*, May 26, 1880.

Ratio of Expansion	Percentage of Water present		Consumption of Steam per Indicated Horse Power per Hour
	At End of Admission	At End of Expansion	
			lb
7.3	24.2	17.8	17.8
9.4	30.8	18.6	17.6
15.1	37.5	20.8	17.7

Here a maximum of efficiency lies between the extreme grades of expansion to which the test extends. In the American experiments the best results were obtained with even more moderate ratios of expansion. The compound engines of the United States revenue steamer "Bache," when tested with steam in the jacket of the large cylinder, with the boiler pressure nearly uniform at 80 lb by gauge, or 95 lb per square inch absolute, and the speed not greatly varied, gave the results shown in Table IV. Here the efficiency is very little affected by a large variation in the cut-off, but when the ratio of expansion becomes excessive a distinct loss is incurred.

TABLE IV.

Ratio of Total Expansion	Consumption of Steam per I.H.P. per Hour
	lb
4.2	21.2
5.7	20
7.0	20.3
9.2	20.7
16.8	25.1

Experiments with engines, in the conditions which hold in ordinary practice, show that it is not unusual to find 20 or 30 per cent. of the steam that comes over from the cylinder condensed during admission. In favourable cases the amount is less than this; occasionally, on the other hand, the amount condensed is as much as half, or even more than half, the whole steam supply.

91. The action of the cylinder walls is reduced—(1) by jacketing, (2) by superheating, and (3) by using compound expansion. The advantage of the steam jacket has been already mentioned. In high-speed engines its beneficial effect is necessarily small, and in certain cases the benefit may be even more than neutralized by the drawbacks which have been alluded to above (§ 88). In general, however, the steam jacket forms a valuable means of reducing the wasteful action of the cylinder walls, especially when the ratio of expansion is considerable. Experiments made with and without a jacket, on the same engine, have shown that jacketing may increase the efficiency by 20 or 25 per cent. When a jacket is working properly it uses, in a single cylinder engine, 4 or 5 per cent., and in a compound engine 8 to 12 per cent., of the whole steam supply.

Effect of superheating. 92. Superheating the steam before its admission reduces the amount of initial condensation, by lessening the quantity of steam needed to give up a specified amount of heat, and this in its turn lessens the subsequent cooling by re-evaporation. That it has a marked advantage in this respect has been experimentally demonstrated by Hirn. On general thermodynamic grounds superheating is good, because it extends the range of temperature through which the working substance is carried. In modern practice superheating (to any considerable extent) is seldom attempted. It occurs to a small extent whenever dry steam is throttled, and a slight superheating is occasionally given to steam in its passage from the high-pressure to the low-pressure cylinder of a compound engine. In former years superheated steam was a common feature of marine practice, but serious practical difficulties caused engineers to abandon its use and to seek economy rather by increasing the initial pressure and using compound expansion. In those days, however, the theoretical advantage of superheating was less understood than it is now. The economy of fuel which its employment would probably secure is so great as to warrant a fresh and energetic attempt to overcome the mechanical difficulties of construction and lubrication that have hitherto stood in the way.

Effect of compound expansion. 93. The most important means of preventing cylinder condensation from becoming excessive is the use of compound expansion. If the vessels were non-conductors of heat it would be, from the thermodynamic point of view, a matter of indifference whether expansion was completed in a single vessel or divided between two or more, provided the passage of steam from one to the other was performed without introducing unresisted expansion (§ 51). But with actual materials the compound system has the important merit that it subjects each cylinder to a greatly reduced range of temperature variation. For this reason the amount initially condensed in the high-pressure cylinder is greatly less than if admission were to take place at once into the low-pressure cylinder and the whole expansion were to be performed there. Further, the steam which is re-evaporated from the first cylinder during its exhaust does work in the second, and it is only the re-evaporation that occurs during the exhaust from the second cylinder that is absolutely wasteful. The exact advantage of this division of range, as compared with expansion (through the same ratio) in a single cylinder, would be hard to calculate; but it is easy to see in a general way that an advantage is to be anticipated, and (though there are isolated instances to the contrary) experience bears out this conclusion. In large engines, working with high pressure, much expansion, and a slow stroke, the fact that compound engines are in general more efficient than single engines cannot be doubted. Additional evidence to the same effect is furnished when a compound engine is tested first with compound expansion and then as a simple engine with the same grade of expansion in the large cylinder alone. Thus in the American experiments the compound engine of the "Bache" when worked as a simple engine used 24 lb of steam per I.H.P. per hour, as compared with about 20 lb when the engine worked compound, with the same boiler pressure, the same total expansion, and steam in the jacket in both cases. The necessity for compounding, if efficiency is to be secured, becomes greater with every increase of boiler pressure. So long as the initial pressure is less than about 100 lb per square inch (absolute) it suffices to reduce the range of temperature into two parts by employing two-cylinder compound engines; with the higher pressures now common in marine practice triple and even quadruple expansion is being introduced.

The action of the cylinder walls would be greatly reduced if it were practicable to use a non-conducting material as an internal lining to the cylinder and to the exposed surfaces of the piston. No cure for the evils of initial condensation would be so effectual as this; and in view of the economy of heat which would result, it is a matter of some surprise that the use of a non-conducting lining has not received more serious attention.

94. The principal reasons have now been named which make the actual results of engine performance differ from the results which would be obtained if the steam conformed in every respect to the simple theory stated in chap. III. It remains to state, very shortly, a few of the results of recent practice as to the actual efficiency of steam engines considered as heat engines. Actual efficiency of steam engines.

The performance of a steam-engine, as regards economy in its consumption of heat, may be stated in a number of ways. In some of these the engine alone is treated as an independent machine; in others the engine, boiler, and furnace are considered as a whole.

The performance of the engine alone is best expressed by stating either (1) the thermodynamic "efficiency" or (2) the number of thermal units used per horse-power per minute. These terms require a short explanation. The "efficiency" of a heat engine has already been defined as the ratio of the work done to the heat supplied. The "work done" ought in strictness to be reckoned as the net work done by the working substance in passing through a complete cycle of operations; it should therefore be determined by subtracting from the work which the substance does in the cylinder the work which is spent upon the substance in the feed pump. The latter is a comparatively small quantity, and engineers generally neglect it in their calculations of thermodynamic efficiency. In making comparison, however, between the efficiency which is actually realized and the efficiency of a perfect engine or of an engine working under any assumed conditions, account should be taken of the negative work done in the feed-pump. Account should also in strictness be taken of that part of the work spent in driving the air-pump which is done upon the working substance, as distinguished from the water of injection. The "heat supplied" is the total heat of the steam delivered to the engine, less the heat contained in the corresponding amount of feed water. This quantity depends on the amount of steam used, on the temperature of the feed, on the boiler pressure, and on the extent to which the boiler "primes." Priming is the delivery by the boiler of water mixed with the steam. Except where there is actual superheating the steam supply is always more or less wet; in a badly designed or overworked boiler large volumes of water may be carried over with the steam, but in a good boiler of adequate size the amount of priming is less (often much less) than 5 per cent. of the whole supply. The effect of priming is, of course, to reduce the supply of heat per lb of the working substance. Modes of statement.

One horse-power is the mechanical equivalent of 42.75 thermal units per minute. The relation between the above two methods of stating engine performance is therefore expressed by the equation

$$\text{Efficiency}=\frac{42.75}{\text{Number of T.U. per I.H.P. per minute}}$$

Another very common mode is to give the number of pounds of steam supplied per horse-power per hour. This is unsatisfactory, even as a method of stating the comparative economy of different engines, or of one engine in different conditions, for several reasons. It ignores variations in boiler pressure, in feed-water temperature, and in the dryness of the supply, although each of these things affects the amount of heat required for the production of a pound of steam. But the total heat of production of dry steam does not vary greatly within the limits of practical pressures; moreover, since (in condensing engines) feed-water is generally taken from the hot-well, its temperature does not differ much from that of the air-pump discharge, or (say), 100° F. Finally, in many comparative trials the amount of priming is nearly if not quite constant. Hence it happens that this mode of statement often furnishes a fairly accurate test of the economy of engines, and it

has the advantage of putting results in a way that is easy to understand and remember

Efficiency of boiler and furnace. 95 None of these modes of statement include the efficiency of the boiler and furnace. The performance of a boiler is most usually expressed by giving the number of pounds of water at a stated temperature converted into steam at a stated pressure by the combustion of 1 lb of coal. The temperature commonly chosen is 212° F, and the water is supposed to be evaporated under atmospheric pressure, the result may then be stated as so many pounds of water evaporated from and at 212° F per 1 lb of coal. But the term "efficiency" may also be applied to a boiler and furnace (considered as one apparatus) in the sense of the ratio between the heat that is utilized and the potential energy that is contained in the fuel. This ratio is, in good boilers, about 0.7. Thus, for example, 1 lb of Welsh coal contains about 15,500 thermal units of potential energy, an amount which is equal to the heat of production (L) of about 16 lb of steam from and at 212°. In practice, however, 1 lb of coal serves to evaporate only about 11 lb of water under these conditions, or about 9.5 lb when the feed water enters at 100° F and the absolute pressure is 100 lb per square inch.

The efficiency of the engine multiplied by that of the furnace and boiler gives a number which expresses the ratio between the heat converted into work and the potential energy of the fuel,—a number which is, in other words, the efficiency of the system of engine, boiler, and furnace considered as a whole. Instead, however, of expressing this idea by the use of the term efficiency, engineers are more usually in the habit of stating the performance of the complete system by giving the number of pounds of coal consumed per horse power per hour. It must be borne in mind that this quantity depends on the performance of the boiler as much as on that of the engine, and that the difference in thermal value between one kind of coal and another makes it, at the best, a rough way of specifying economy. It is, however, an easy quantity to measure, and to most users of engines the size of the coal bill is a matter of greater interest than any results of thermodynamic analysis.

"Duty" Still another expression for engine performance, similar to this last, is the now nearly obsolete term "duty," or number of foot pounds of work done for every 1 cwt of coal consumed. Its relation to the pounds of coal per horse power per hour is this—

$$\text{Duty} = \frac{112 \times 33000 \times 60}{\text{Number of lbs of coal per I H P per hour}}$$

A good condensing engine of large size, supplied by good boilers, consumes about 2 lb of coal per horse power per hour, its duty is then about 110 millions.

Results of trials. 96 To illustrate the subject of this chapter more fully the following summary is given of the results of tests of pumping engines by Mr J G Mair, described in two excellent papers in *Min Pro Inst Civ Eng* (vols lxx and lxxix). The first group (Table V) refers to single cylinder beam rotative engines, all of the same type, working at about 120 horse power (in all except the last trial there were steam-jackets in use) —

Boiler Pressure (Abs)	Total Ratio of Expansion	Percentage of Water Present at Cut off	Lbs of Dry Steam per I H P per Hour	Efficiency
48	6.8	44	22.1	0.099
57	4.3	29	22.1	0.099
59	3.2	22	21.3	0.102
59	1.9	15	23.6	0.093
56	3.8	37	26.5	0.083

In these engines, which ran at the slow speed of about 20 revolutions per minute, the influence of steam jacketing was very marked. In the trials made with jackets in action, the percentage of water present at cut off, when plotted in relation to the ratio of expansion gives a diagram which is sensibly a straight line, by drawing this line it may be seen that with an expansion of 3.8 in a similar jacketed cylinder there would be about 25 per cent of initial condensation instead of the much greater amount (37 per cent) which the absence of a jacket caused in the last trial.

The next group of tests (Table VI) refer to compound engines, of the types named (for explanation of the terms see chap VI) [1]—

Type	Boiler Pressure Abs	Total Ratio of Expansion	Number of Revolutions per Minute	Percentage of Water present at Cut off	Lbs of Dry Steam per I H P per Hour	Efficiency
Woolf beam, without jackets	58	9.3	18	51	26.6	0.082
" with jackets	62	15.8	20	41	17.3	0.126
" without jackets	89	7.8	34	34	19.2	0.113
" with jackets	88	9.6	34	38	17.4	0.125
" "	68	11.9	18	25	15.6	0.139
" "	78	16.5	23	31	15.5	0.140
" "	75	13.2	27	29	15.1	0.144
Woolf tandem, without jackets	66	11.5	60	43	21.6	0.101
Receiver beam, with jackets	76	13.6	24	34	14.8	0.147

[1] For other comparative trials, see Hallauer's papers, especially *Bull Soc Ind de Mulhouse*, Dec 30, 1878, and May 26, 1880

V THE TESTING OF STEAM ENGINES

Objects of tests. 97 Under this head we may include experiments made to determine—(*a*) the horse-power of an engine, (*b*) the thermodynamic efficiency, or some more or less nearly equivalent quantity, such as the relation of power to steam supply or to coal consumption (§ 95), (*c*) the distribution of steam, that is, the relation which the several events of steam admission, expansion, exhaust, and compression bear to the stroke of the piston, (*d*) the amount of initial condensation, the wetness of the steam throughout the stroke, and the transfer of heat between it and the cylinder walls, (*e*) the efficiency of the mechanism, or the ratio which the work done by the engine on the machinery it drives bears to the work done by the steam in the cylinder.

Tests (*a*) and (*c*) are of common application, test (*b*), in the simple form of a comparison of horse-power with coal burnt per hour, is not unusual. The actual measurement of efficiency, whether thermodynamic (*b*) or mechanical (*e*), and the analysis involved in (*d*) have been carried out in comparatively few instances.

The indicator. 98 In all these operations the taking of indicator diagrams forms a principal part. The indicator, invented by Watt and improved by M'Naught and by Richards, consists of a small steam cylinder, fitted with a piston which slides easily within it and is pressed down by a spiral spring of steel wire. The cylinder of the indicator is connected by a pipe below this piston to one or other end of the cylinder of the engine, so that the piston of the indicator rises and falls in response to the fluctuations of pressure which occur in the engine cylinder. The indicator piston actuates a pencil, which rises and falls with it and traces the diagram on a sheet of paper fixed to a drum that is caused to rotate back and forth through a certain arc, in unison with the motion of the engine piston. In M'Naught's indicator the pencil is directly attached to the indicator piston, in Richards's the pencil is moved by means of a system of links so that it copies the motion of the piston on a magnified scale. This has the advantage that an equally large diagram is drawn with much less movement of the piston, and errors which are caused by the piston's inertia are consequently reduced. In high speed engines especially it is important to minimize the inertia of the indicator piston and the parts connected with it. In Richards's indicator the linkage employed to multiply the piston's motion is an arrangement similar to the parallel motion introduced by Watt as a means of guiding the piston rod in beam engines (see § 188). In several recent forms of indicator lighter linkages are adopted, and other changes have been made with the object of fitting the instrument better for high-speed work. One of these modified forms of Richards's indicator (the Crosby) is shown in fig 21. The pressure of steam in the engine cylinder raises the piston P, compressing the spring S and causing the pencil Q to rise in a nearly straight line through a distance proportional, on a magnified scale, to the compression of the spring and therefore

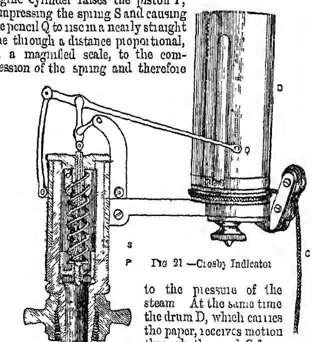

FIG 21 —Crosby Indicator

to the pressure of the steam. At the same time the drum D, which carries the paper, receives motion through the cord C from the crosshead of the engine. Inside this drum there is a spiral spring which becomes wound up when the cord is pulled, and serves to turn the drum in the reverse direction during the back stroke. The cap of the indicator cylinder has holes in it which admit air freely to the top of the piston, and the piston has room to descend, extending the spring S, when the pressure of the steam is less than that of the atmosphere. The spring is easily taken out and replaced by a more or less stiff one when higher or lower pressures have to be dealt with.

Errors in diagrams. 99 To register correctly, an indicator must satisfy two conditions (1) the motion of the piston must be proportional to the change of steam pressure in the engine cylinder, and (2) the motion of the drum must be proportional to that of the engine piston.

The first of these requires that the pipe which connects the

indicator with the cylinder should be short and of sufficient bore, and that it should open in the cylinder at a place where the pressure in it will not be affected by the kinetic action of the inrushing steam. Frequently pipes are led from both ends of the cylinder to a central position where the indicator is set, so that diagrams may be taken from either end without shifting the instrument; much better results are obtained, especially when the cylinder is long, by using a pair of indicators, each fixed with the shortest possible connecting pipe, or by taking diagrams successively from the two ends of the cylinder with a single instrument set first at one end and then at the other. The general effect of an insufficiently free connexion between the indicator and the engine cylinder is to make the diagram too small. The first condition is also invalidated to some extent by the friction of the indicator piston, of the joints in the linkage, and of the pencil on the paper. The piston must slide very freely; nothing of the nature of packing is permissible, and any steam that leaks past it must have a free exit through the cover. The pencil pressure must not exceed the minimum which is necessary for clear marking. By careful use of a well made instrument the error due to friction in the piston and connected parts need not be serious. Another source of disturbance is the inertia of these parts, which tends to set them into oscillation whenever the indicator piston suffers a comparatively sudden displacement. These oscillations, superposed upon the legitimate motions of the piston, give a wavy outline to parts of the diagram, especially when the speed is great and when the last named source of error (the friction) is small. When they appear on the diagram a continuous curve should be drawn midway between the crests and hollows of the undulations. To keep them within reasonable compass in high speed work a stiff spring must be used and an indicator with light parts should be selected. Finally, to secure accuracy in the pencil's movement, the strain of the spring must be kept well within the limit of elasticity, so that the strain may be as nearly as possible proportional to the steam pressure. Care must be taken that the spring is graduated to suit the temperature (about 212° F.) to which it is exposed when in use; its stiffness at this temperature is about 3 per cent less than when cold.

With regard to the motion of the drum, it is, in the first place, necessary to have a reducing mechanism which will give a sufficiently accurate copy, on a small scale, of the engine piston's stroke. Many contrivances are used for this purpose; in some a rigorous geometrical solution of the problem is aimed at, in others a close approximation only. Fig. 22 shows a good form of indicator gear. A pendulum rod AB is pinned at one end to the crosshead A (the end of the piston-rod) of the engine. Its upper end is carried by a pin which is free to turn and slide in the fixed slot B. A cord from an intermediate point C leads over pulleys to the indicator drum. The pendulum rod should be much longer than the piston stroke, and the cord should lead off for a considerable distance in the direction sketched, at right angles to the mean position of the rods. The accuracy of the drum's motion does not, however, depend merely on the geometrical condition of the gear. It depends also on the rigidity of the parts, and especially on the stretching of the cord. The elasticity of the cord will cause error if it is not maintained in a state of uniform tension throughout the double stroke, and this error will be greater the longer and the more extensible the cord is. Hence short cords are to be preferred, and fine wire, which stretches much less, may often be substituted for cord with great advantage. The stretching of the cord is perhaps the most serious and least noticed source of error the indicator is subject to in ordinary practice. The tension of the cord varies for three reasons,—the inertia of the drum, the varying resistance of the drum spring, and the friction of the drum, which has the effect of increasing the tension during the forward stroke and of reducing it during the back stroke. This last cause of variation can be minimized only by good construction and careful use of the instrument; but the other two causes can be made to neutralize one another almost completely. Since the motion is nearly simple harmonic, the acceleration of the drum varies in a nearly uniform manner from end to end of the stroke. The resistance of the drum spring also varies uniformly; and it is therefore only necessary to adjust the stiffness of the drum spring so that the increase in its resistance as the motion of the drum proceeds may balance the decrease in the force that the cord has to exert in setting the drum into motion. This adjustment will secure an almost uniform tension in the cord throughout the whole stroke; it must, of course, be altered to suit different engine speeds. The indicator plays so important a part in the testing of heat engines, whether for practical or scientific purposes, that no pains should be spared to avoid the numerous and serious sources of error to which it is liable through faulty construction or unintelligent use.[1]

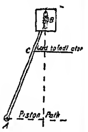

Fig. 22.—Indicator Gear.

[1] A valuable discussion and experimental investigation of the errors of the indicator will be found in papers by Prof. Osborne Reynolds and Mr H. W. Brightmore (*Min. Proc. Inst. C.E.*, vol. lxxxiii., 1886). In the discussion which followed the reading of the papers a description will be found of an ingenious apparatus which the makers of the Crosby indicator employ to test the uniformity of the cord's tension throughout the stroke.

100. To determine the indicated horse power, the mean effective pressure is found by dividing the area of the diagram by the length of its base. This gives a mean height, which, interpreted on the scale of pressures, is the mean effective pressure in pounds per square inch. This has to be multiplied by the effective area of the piston in square inches and by the length of the piston stroke in feet, to find the work done per stroke in foot pounds on that side of the piston to which the diagram refers. Let A_1 be the area of the piston on one side and A_2 on the other, p_1 and p_2 the mean effective pressures on the two sides respectively, L the length of the stroke in feet, and n the number of complete double strokes or revolutions per minute. Then the indicated horse-power Measurement of horse power.

$$\text{I.H.P.} = \frac{n\text{L}(p_1\text{A}_1 + p_2\text{A}_2)}{33000}.$$

In finding the mean pressure the area of the diagram may be conveniently measured by a planimeter or calculated by the use of Simpson's rule. A less accurate plan, frequently followed, is to divide the diagram by lines drawn at the middle of strips of equal width, as in figs. 23 and 24, and to take the mean pressure as the average height of these lines.

101. Space admits of no more than a few illustrations of actual indicator diagrams. Fig. 23 is a diagram taken from an antiquated non-condensing engine working without expansion. The line AB has been drawn at a height which represents the boiler pressure, in order to show the loss of pressure in admission. The line CD is drawn at atmospheric pressure by the indicator itself. In this engine admission continues till the end of the forward stroke, and as a result the back pressure is great, especially during the first stage of the exhaust. The diagram shows a slight amount of oscillation produced by the sudden admission of steam. This feature, however, is better illustrated by fig. 24, which is another diagram taken from the same engine, at the same boiler pressure, but with the steam much throttled. Examples of indicator diagrams.

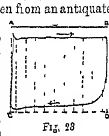

Fig. 23.

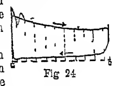

Fig. 24.

Fig. 25 shows a pair of diagrams taken from a condensing engine in which the distribution of steam is effected by a common slide valve (chap. VIII.). The two diagrams refer to opposite ends of the cylinder and are taken on the same paper by the plan already alluded to (§ 99) of fixing the indicator about midway between the ends of the cylinder, with a pipe leading from it to each end. Steam is cut off at a and a', release occurs at b and b', and compression begins at c and c'. The gradual closing of the slide valves throttles the steam considerably before the cut off is complete. The line of no pressure EF is drawn 14.7 lb per square inch below CD, which is the atmospheric line; and the line of no volume AE or BF is drawn (for each end of the cylinder) at a distance (from the end of the diagram) equal to the volume of the clearance.

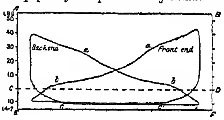

Fig. 25.—Indicator Diagram from Condensing Engine, with Slide Valve.

Fig. 26 is a diagram taken from a Corliss engine working with a large ratio of expansion. The Corliss valve-gear, which will be described in chap. IX., causes the admission valve to close suddenly, and consequently defines the point of cut off pretty sharply in the diagram. Through this point a dotted curve has been drawn (by aid of the equation $\text{PV}^n = \text{const.}$, § 67), which is the curve that would be followed if the expansion were adiabatic. In drawing this curve it has been assumed that at the end of admission the steam contains 25 per cent of water. The actual curve first falls below and then rises above this adiabatic curve, in consequence of the continued condensation which takes place during the early stages of the expansion and the re-evaporation of condensed water during later stages (§ 82). Fig. 27 is another diagram from a Corliss engine, running light, and with the condenser not in action. Diagrams of this kind are often taken when engines are first erected, for the purpose of testing the setting of the valves. Other indicator diagrams, for compound engines, will be given in chap. VI.

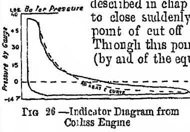

Fig. 26.—Indicator Diagram from Corliss Engine.

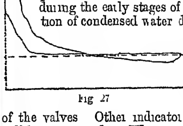

Fig. 27.

In place of the ordinary indicator an apparatus is occasionally used which integrates the two coordinates which it is the business of the indicator diagram to represent, and exhibits the power developed from stroke to stroke by the progressive movement of an index round a dial.

Tests of thermodynamic efficiency. 102. In tests of thermodynamic efficiency we may measure either the heat supplied or the heat rejected, and compare it with the work done. The heat supplied is on the whole capable of more exact measurement, but in any case a determination of the heat rejected furnishes a valuable check on the accuracy of the result. The trial must be continued for a period of some hours at least, during which the engine and boiler are to be kept working as uniformly as possible in all respects. The power is determined by taking indicator diagrams at short intervals. The heat supplied is found by noting the amount of feed water required to keep the water level in the boiler constant during the trial, the temperature of the feed, and the pressure of the steam. The only uncertainty which attaches to the measurement of heat supply is due to priming. Every pound of water that passes over unevaporated to the engine takes less heat by the amount L (§ 60) than if it went over in the state of steam. To measure the degree of wetness in steam is a matter of some difficulty; it may be done by passing the steam into a known quantity of cold water, so as to condense it, and observing the rise of temperature which has taken place when the whole quantity of water present has increased by a measured amount.

Heat supplied. If L_1 be the latent heat of steam at the boiler pressure, h_0 the heat in the feed-water per lb, h_1 the heat in the boiler water per lb, and q the dryness of the steam as it leaves the boiler, the heat taken in per lb of the substance supplied to the cylinder is

$$qL_1+h_1-h_0$$

To this must be added, in the case of a jacketed engine, the heat supplied to the jacket, a quantity which depends on the amount of steam condensed there, and also on whether the water that gathers in the jacket is drained back into the boiler or allowed to escape into the hot-well.

Heat rejected. The heat rejected by an engine fitted with an injection condenser is made up of the following parts:—(*a*) heat rejected in the condensed water, less the heat returned to the boiler in the feed (if the feed is directly drawn from the hot well without giving the water time to cool sensibly, this quantity vanishes; in a jacketed engine this item must include the heat rejected in the jacket drains); (*b*) heat used in warming the condenser water from the temperature of injection to the temperature of the air pump discharge; (*c*) heat rejected in air and vapour from the air-pump; (*d*) heat lost by radiation, conduction to supports, and aerial convection,—or, more properly, the excess of this heat over the heat developed within the engine by the friction of piston, valves, &c. Of these quantities, (*a*) is found without difficulty from a knowledge of the amount of the feed-water, its temperature, the temperature of the air pump discharge, and amount and temperature of water drained from the jacket; (*b*) is measured by gauging the whole discharge from the pump, deducting from it the amount returned to the boiler as feed-water, and measuring its temperature and that of the injection water; (*c*) does not admit of direct measurement; (*d*) may be approximately estimated for a jacketed engine by filling the jacket with steam while the engine is out of action, and observing the amount of steam condensed in the jacket during a long interval, through radiation, &c., from the external surface.

In calculating the supply of heat by the boiler it is convenient to take the temperature 32° F. as a starting point from which to reckon what may be termed the gross supply, and then to deduct from this the heat which is restored to the boiler in the feed water. The difference, which may be called the net supply, is the true consumption of heat, and is to be used in calculating the efficiency of the engine. A similar convention may be followed in dealing with the heat rejected.

Example. 103. This subject is most easily made intelligible by help of a numerical example. For this purpose the following data of an actual engine test have been taken from one of Mr Mair's papers[1]; the data have been independently reduced, with results that differ only to a small and unimportant extent from those stated by Mr Mair. The engine under trial was a compound beam engine, steam jacketed, with an intermediate receiver between the cylinders. The cylinders were 21 inches and 36 inches in diameter, and the stroke $5\frac{1}{2}$ feet. The total ratio of expansion was 13.6.

Data

Boiler pressure, absolute, 76 lb per sq in	
Time of trial	6 hours
Revolutions	8632, or 24.0 per min
I.H.P.	127.4
Feed water	12,032 lb, or 1.394 lb per rev. (M.)
Air pump discharge	1226 lb per min., or 51.1 lb per rev
Water drained from jackets	1605 lb, or 0.186 lb per rev. (M_J)
Percentage of priming	4
Temperature of feed, t_0	59°
Temperature of injection, t_2	50°
Temperature of air pump discharge, t_3	73°.4

[1] *Min. Proc. Inst. C.E.*, vol. lxx.

Results

Dryness of boiler steam, $q=0.96$

Supply to cylinder, $M_c=M-M_J=1.028$ lb per rev

Injection water per rev. $=51.1-1.208=49.9$ lb

$L_1=898$, $h_1=278$, $h_2=18$, $h_3=41.4$, $h_0=27$

Gross supply of heat from boiler to cylinder per revolution

$$=M_c(qL_1+h_1)$$
$$=1.208\,(0.96\times898+278)=1377 \text{ T.U.}$$

Gross supply of heat from boiler to jackets per revolution

$$=M_J\,(qL_1+h_1)$$
$$=0.186\,(0.96\times898+278)=212 \text{ T.U.}$$

Total gross supply per revolution $=1377+212=1589$ T.U.

Heat restored to boiler per revolution,

By feed water $=Mh_0=1.394\times27=38$ T.U.

By jacket drains $=0$

Net supply of heat per revolution $=1589-38=1551$ T.U.

Heat converted into work, per revolution

$$=\frac{\text{I.H.P.}\times42.75}{24}=227 \text{ T.U.}$$

Total heat rejected per revolution $=1551-227=1324$ T.U.

The rejected heat is accounted for as follows:—

Net heat rejected in air pump discharge = Gross heat rejected in air pump discharge − heat in injection water − heat restored to the boiler by the feed

$$=51.1\times41.4-49.9\times18-38=1179 \text{ T.U.}$$

Heat rejected in jacket drains $=M_J h_1=0.186\times278=52$ T.U.

These two items account for 1231 units of rejected heat and leave a balance of 93 units unaccounted for. The balance is made up of heat rejected in air and vapour by the air pump, heat lost by radiation, &c., and errors of experiment. In the example considered the loss by radiation was estimated at 45 thermal units, which reduces the discrepancy between the two sides of the account to 48 units, or only about 3 per cent. of the whole heat supplied.

The efficiency of the engine is $\frac{227}{1551}$ or 0.146. The efficiency of a perfect engine working between the same limits of temperature, 308° F. and 50° F., would be 0.335.

Calculation of the wetness of the steam. 104. When it is desired to deduce from the test of an engine not only the thermodynamic efficiency but also the amount of initial condensation and the subsequent changes of wetness which the working fluid undergoes during expansion, it is necessary to know, in addition to the above data, the volume of cylinder and clearance, the relation of pressure to volume during the several stages of the stroke, and the whole amount of working substance present in the cylinder. This last is a quantity whose precise value is not easily ascertained. Assuming that the point at which compression begins can be distinguished on the diagram, we have the pressure and the volume of the steam that is afterwards compressed into the clearance space. From its pressure and volume we can infer its amount, if only its degree of dryness be known. The assumption usually made is that at the beginning of compression the steam shut up in the cylinder is dry. This assumption is to a certain extent supported by the fact that re-evaporation has been going on during expansion and exhaust; in good engines it is probably not far from the truth, though there are cases where, owing to excessive initial condensation and to the exhaust ports being badly situated for draining the cylinder, water may accumulate in considerable quantities. Except in extreme cases of this kind, however, the assumption that the steam is dry when compression begins does not introduce an error which can seriously affect the subsequent calculations. Having found the quantity shut up in the clearance, we add to it the quantity delivered from the boiler per single stroke, to find the whole quantity of working substance in the cylinder. The substance is, and continues, a mixture in varying proportions of steam and water. Its volume may practically be taken as the volume of the dry steam it contains, the volume of the water being comparatively small. Taking any point of the stroke, and measuring the pressure and the volume there, we can say how much steam (at that pressure) would be required to fill the volume which the mixture then occupies. This quantity will always be less than the actual amount of the mixture, and the difference between them is the amount of water that is present. This calculation is of special interest at two places in the stroke—the point of cut off and the point of release.

105. To illustrate it we may continue the numerical example quoted above. In the high-pressure cylinder of the engine to which the test refers the volume at the beginning of compression (including clearance) was 1.52 cubic feet. The pressure, just before compression began, is shown by the indicator diagram (of which fig. 28 is a copy) to have been 14.8 lb per square inch. At this pressure the density (or mass of 1 cubic foot) of steam is 0.038 lb. Hence (on the above assumption that the steam was then dry) the quantity shut up in the clearance was $1.52\times0.038=0.058$ lb. Example

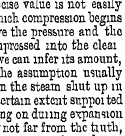

Fig. 28.

The amount delivered to the cylinder per single stroke (or half revolution) was 0.604 lb. The whole quantity of working substance present from the end of the admission to the beginning of the exhaust was therefore 0.662 lb.

At the point of cut off the pressure is shown by the diagram to have been 64 lb per square inch (absolute), and the volume, including clearance, was 2.92 cubic feet. The density of steam for this

pressure is 0·151 lb per cubic foot. Hence, out of the whole mixture, the amount of steam was $2·92 \times 0·151 = 0·440$ lb. The water present at the point of cut off was therefore $0·662 - 0·440$ or 0·222 lb. This is 33·5 per cent. of the whole amount of the mixture, and shows (after allowing for the priming water) that about 32 per cent. of the steam admitted was condensed on admission.

Next, to find the amount of water present at the end of the expansion. The diagram shows that at this point the pressure was 15·2 lb per square inch and the volume 13·235 cubic feet. Steam of this pressure has a density of 0·0392 lb per cubic foot. The quantity of steam at release was therefore $13·235 \times 0·0392$, or 0·519 lb, and the quantity of water $0·662 - 0·519 = 0·143$ lb. It appears therefore that re-evaporation from the cylinder walls during expansion reduced the amount of water present by 0·079 lb, so that the percentage of water fell from 33·5 at the point of cut off to 21·6 at the point of release. The same method of calculation can obviously be applied to any other point in the expansion curve, and can be extended to the low pressure cylinder of an engine which (like the one in this example) is compound. The amount of dry steam present at the point of release is sometimes spoken of as the "steam accounted for by the indicator diagram."

Transfers of heat.

106. Having completed this analysis of the working substance, we may proceed to find the quantity of heat which it gives to or takes from the walls of the cylinder during any stage of its action, by considering the changes of internal energy which the working substance undergoes, along with the external work done, from stage to stage. If we write m for the amount of steam and m' for the amount of water present in the cylinder at any one stage, the internal energy of the mixture is (§ 62)

$$(m+m')h + m\rho$$

Let the value of this quantity be denoted by I_A at any one stage in the expansion or compression of the mixture, such as the point of cut-off A, and by I_B at a later stage, such as the point of release B, the corresponding volumes of the whole mixture being V_A and V_B respectively. Then in passing from the first condition to the second the substance loses $I_A - I_B$ of internal energy. It also does an amount of external work W_{AB} measured by $\int_{V_A}^{V_B} PdV$, or the area of the figure ABab. If W_{AB} is equal to $I_A - I_B$ the process is adiabatic; otherwise the amount of heat taken up (from the cylinder walls) during the process is

$$Q_{AB} = W_{AB} - (I_A - I_B).$$

If A is the point of cut off and B that of release, the quantity so calculated is the heat taken up from the cylinder walls during the whole process of expansion. The calculation applies equally, however, in determining the heat taken up during any stage of the process. When this has a negative value heat has been given up by the substance to the cylinder walls. In the numerical example which has been cited above the internal energy of the mixture at the beginning of expansion was 540 thermal units. At the end of expansion the internal energy was 584 thermal units. Between these points the indicator diagram (fig. 28) shows that the work done was equivalent to 55 thermal units. $44 + 55 = 99$ units of heat were therefore taken from the cylinder walls during the process of expansion. A similar calculation, applied to the compression curve, shows that in that part of the operation heat was given up to the cylinder walls. During compression W is of course negative, since work is then spent upon the steam.

107. During admission and also during exhaust another item enters into the account,—the amount of the working substance is then undergoing change. To find the heat given up by the steam during admission we have first to calculate (by the method already described) the internal energy of the mixed steam and water that is shut into the clearance space at the end of the previous stroke; this may be called I_D. The steam which then enters brings with it an additional amount of internal energy which we may calculate from a knowledge of the quantity of steam, its pressure at admission, and its dryness. Let I_O denote this additional supply of internal energy. At the end of admission the state of the mixture is known from the indicator diagram; hence its internal energy I_A may be found. The work done during admission, W_{DA}, is also determined from the diagram. Then we have, for the heat given up by the steam during admission,

$$Q_{DA} = I_D + I_O - I_A - W_{DA}.$$

In attempting to apply the same method of calculation to determine the heat taken up from the cylinder walls during exhaust (Q_{BC}), we are met by the difficulty that we do not know the state, as regards dryness, of the mixture during its expulsion from the cylinder. We may, however, estimate the value of Q_{BC} as follows. Let Q_{CD} and Q_{DA} be, as before, the heat given up by the steam to the cylinder walls during compression and admission respectively, and let Q_{AB} be the heat taken from the cylinder walls during exhaust; also let Q_R be the heat which the cylinder loses (per single stroke) by radiation (less the heat produced by piston and valve friction), and Q_J the heat which it gains by condensation of steam in the jacket, if there is one. Then, as the cylinder neither gains nor loses heat on the whole, after a uniform regime has been arrived at, we have

$$Q_{BC} = Q_{CD} + Q_{DA} + Q_J - Q_R.$$

The quantity Q_{BC} may also be calculated directly from a knowledge of the gross heat rejected to the condenser, since the gross heat rejected is

$$I_B + W_{BC} + Q_{BC},$$

I_B being the internal energy of the mixture at release and W_{BC} being the work done upon the steam in expelling it from the cylinder.

Waste of heat by action of cylinder walls.

108. This heat Q_{BC}, which is taken up by the steam from the cylinder walls during exhaust, is a part of the heat deposited there during admission. It has passed through the cylinder without contributing in the smallest degree to the work of the engine. Probably for this reason it is treated by some writers as a quantity which measures the wasteful influence of the cylinder walls. This, however, is not strictly the case. The magnitude of Q_{BC} is certainly in some sense an index of the extent to which the alternate heating and cooling of the metal causes inefficiency; it is so much heat absolutely lost, and lost by the action of the walls. [In the high pressure cylinder of a compound engine this loss is, of course, absolute only as regards that cylinder; the heat represented by Q_{BC} assists in the work of the low-pressure cylinder.] But besides this loss there is another which the walls cause by taking heat from the steam on admission and restoring it during the later stages of expansion. That part of the heat abstracted during admission which is restored before the point of release does not appear in Q_{BC}; nevertheless it is a source of inefficiency. With steam that is dry at the end of the expansion the value of Q_{BC} is almost negligible; still the cylinder walls may cause a very sensible loss by abstracting heat from the hot steam as it enters and restoring it as the mixture expands. The quantity which has been denoted here by Q_{BC}—that heat, namely, which the steam takes up from the cylinder walls after release and during exhaust—appears in the writings of Hirn and his followers under the symbol R_c. He terms it "le refroidissement au condenseur," and refers to it, somewhat inexactly, as "l'effet réel des parois."[1] Prof. Cotterill applies the name "exhaust waste" to the sum of the two quantities Q_{BC} and Q_R.[2]

109. It is obvious that the above analysis depends fundamentally on the strict accuracy with which the indicator diagram not only gives a measure of the work done by the engine under test, but shows the relation of pressure to volume at each stage in the process. Engine tests of a complete kind have now been made and discussed by a number of independent observers, working with widely different data. The results are in good general agreement. They demonstrate the influence of the sides beyond question, showing that 30 per cent. is no unusual amount of water to be present in the mixture at the point of cut-off, even in compound engines of the best types, that half of this water, or even more, is frequently found at the end of expansion, and that the heat denoted above by Q_{BC} ranges from about 10 to 20 per cent. of the whole heat supplied.[3]

Efficiency of the mechanism.

110. An engine employed to drive other machinery delivers to it an amount of power less than the indicated power by an amount which is wasted in overcoming the friction of piston and piston-rod, slides, valves, journals, &c. The efficiency of the mechanism is the ratio of the "effective" or "brake" horse power to the indicated horse power. It may be tested by measuring the power delivered by the engine when at work, either by using a transmission dynamometer or by substituting an absorption dynamometer for the mechanism usually driven. In the case of a pumping engine the efficiency of the engine and pumps together may be determined by observing the actual work done in raising water or in delivering a measured volume against a known pressure. Attempts are sometimes made to find the amount of power wasted in engine friction by testing the indicated power needed to drive the engine against no other resistance than its own friction. This, however, fails to show the power which will be spent in overcoming friction when the engine runs under ordinary conditions, since the pressures at the slides, the journals, and elsewhere are then widely different from what they are when the engine is running without load. Experiments with large engines show that the efficiency of the mechanism may, in favourable cases, be 0·85 or even 0·9; in small engines, or in large engines running under light loads, it is generally much less than this.

[2] *The Steam Engine considered as a Heat Engine*, p. 54.

[3] In this connexion reference should be made to the data supplied by the American experiments (of Messrs Emery and Loring), some of which are discussed fully by Prof. Cotterill; also to the writings of Hirn and the extensive researches of the Alsatian engineers alluded to in chap. IV.; also to Mr Mair's paper (§ 96) and to Mr M. Longridge's *Reports*, as engineer to the Engine, Boiler, and Employers' Liability Association, for 1880, 1881, and 1884. The *Report* for 1884 especially exhibits the results of a test with unique fulness and clearness. The *Journal* of the Franklin Institute for 1885 contains an account of experiments by Messrs Gately and Kletzsch on one engine, under varied conditions of boiler pressure, expansion, and speed; these, so far as they go, confirm the conclusions stated, on general grounds, in chap. IV. For a synopsis of Hirn's method of analysis reference should be made to a paper by M. Pouparin, *Bull. Soc. Ind. de Mulhouse*, March 31, 1875.

VI. COMPOUND EXPANSION

Woolf engine

111. In the original form of compound engine, invented by Hornblower and revived by Woolf, steam passed directly from the first to the second cylinder, the exhaust from the first and admission to the second went on together throughout the whole of the back stroke. This arrangement is possible only when the high and low pressure pistons begin and end their strokes together, that is to say, when their movements either coincide in phase or differ by half a revolution. Engines of the "tandem" type satisfy this condition—engines, namely, whose high and low pressure cylinders are in one line, with one piston rod common to both pistons. Engines in which the high and low pressure cylinders are placed side by side, and act either on the same crank or on cranks set at 180° apart, may also discharge steam directly from one to the other cylinder; the same remark applies to beam engines, whether of the class in which both pistons act on one end of the beam, or of the class introduced by M'Naught, in which the high and low pressure cylinders stand on opposite sides of the centre. By a convenient usage which is now pretty general the name "Woolf engine" is restricted to those compound engines which discharge steam directly from the high to the low pressure cylinders without the use of an intermediate receiver.

Receiver engine

112. An intermediate receiver becomes necessary when the phases of the pistons in a compound engine do not agree. With two cranks at right angles, for example, a portion of the discharge from the high pressure cylinder occurs at a time when the low pressure cylinder cannot properly receive steam. The receiver is in some cases an entirely independent vessel connected to the cylinders by pipes; very often, however, a sufficient amount of receiver volume is afforded by the valve casings and the steam-pipe which connects the cylinders. The receiver, when it is a distinct vessel, is frequently jacketed.

The use of a receiver is of course not restricted to engines in which the "Woolf" system of compound working is impracticable. On the contrary, it is frequently applied with advantage to beam and tandem compound engines. Communication need not then be maintained between the high and low pressure cylinders during the whole of the stroke; admission to the low pressure cylinder is stopped before the stroke is completed, the steam already admitted is allowed to expand independently, and the remainder of the discharge from the high pressure cylinder is compressed into the intermediate receiver. Each cylinder has then a definite point of cut off, and by varying these points the distribution of work between the two cylinders may be adjusted at will. In general it is desirable to make both cylinders of a compound engine contribute equal quantities of work. If they act on separate cranks this has the effect of giving the same value to the mean twisting moment on both cranks.

Compound diagrams

113. Wherever a receiver is used, care should be taken that there is no unresisted expansion into it, in other words, the pressure in the receiver should be equal to that in the high pressure cylinder at the moment of release. If the receiver pressure is less than this there will be what is termed a "drop" in the steam pressure between the high-pressure cylinder and the receiver, which will show itself in an indicator diagram by a sudden fall at the end of the high-pressure expansion. This "drop" is, from the thermodynamic point of view, irreversible, and therefore wasteful. It can be avoided by selecting a proper point of cut off in the low pressure cylinder. When there is no "drop" the expansion that occurs in a compound engine has precisely the same effect in doing work as the same amount of expansion in a simple engine would have, provided the law of expansion be the same in both and the waste of energy which occurs by the friction of ports and passages in the transfer of steam from one to the other cylinder be negligible. The work done in either case depends merely on the relation of pressure to volume throughout the process, and so long as that relation is unchanged it is a matter of indifference whether the expansion be performed in one vessel or in more than one. It has, however, been fully pointed out in chap IV that in general a compound engine has a thermodynamic advantage over a simple engine using the same pressure and the same expansion, inasmuch as it reduces the exchange of heat between the working substance and the cylinder walls and so makes the process of expansion more nearly adiabatic. The compound engine has also a mechanical advantage which will be presently described. The ultimate ratio of expansion in any compound engine is the ratio of the volume of the low-pressure cylinder to the volume of steam admitted to the high pressure cylinder. Fig 29 illustrates the combined action of the two cylinders in a hypothetical compound engine of the Woolf type, in which for simplicity the effect of clearance is neglected and also the loss of pressure which the steam undergoes in transfer from one to the other cylinder. ABCD is the indicator diagram of the high pressure cylinder. The exhaust line CD shows a falling pressure in consequence of the increase of volume which the steam is then undergoing through the advance of the low pressure piston. EFGH is the diagram of the low pressure cylinder drawn alongside of the other for convenience in the construction which follows. It has no point of cut-off, its admission line is the continuous curve of expansion EF, which is the same as the high-pressure exhaust line CD, but drawn to a different scale of volumes. At any point K, the actual volume of the steam is KL + MN. By drawing OP equal to KL + MN, so that OP represents the whole volume, and repeating the same construction at other points of the diagram, we may set out the curve QPR, the upper part of which is identical with BC, and so complete a single diagram which exhibits the equivalent expansion in a single cylinder.

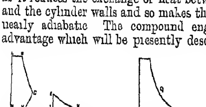

FIG 29.—Compound Diagrams. Woolf type.

In a tandem compound engine of the receiver type the diagrams resemble those shown in fig 30. During CD (which corresponds to FG) expansion is taking place into the large or low pressure cylinder. D and G mark the point of cut off in the large cylinder, after which GH shows the independent expansion of the steam now shut within the large cylinder, and DE shows the compression of steam by continued discharge from the small cylinder into the receiver. At the end of the stroke the receiver pressure is OE, and this must be the same as the pressure at C, if there is to be no "drop." Diagrams of a similar kind may be sketched without difficulty for the case of a receiver engine with any assigned phase relation between the pistons.[1]

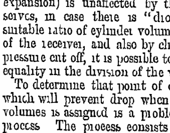

FIG 30.—Compound Diagrams. Receiver type.

"Drop" in the receiver

114. By making the cut-off take place earlier in the large cylinder we increase the mean pressure in the receiver, the work done in the small cylinder is consequently diminished. The work done in the large cylinder is correspondingly increased, for the total work (depending as it does on the initial pressure and the total ratio of expansion) is unaffected by the change. The same adjustment serves, in case there is "drop," to remove it. By selecting a suitable ratio of cylinder volumes to one another and to the volume of the receiver, and also by choosing a proper point for the low-pressure cut off, it is possible to secure absence of drop along with equality in the division of the work between the two cylinders.

To determine that point of cut off in the low pressure cylinder which will prevent drop when the ratio of cylinder and receiver volumes is assigned is a problem most easily solved by a graphic process. The process consists in drawing the curve of pressure during admission to the low pressure cylinder until it meets the curve of expansion which is common to both cylinders.[2] Thus in fig 31 (where for the sake of simplicity the effects of clearance are neglected) AB represents the admission line and BC the expansion line in the small cylinder. Release occurs at C, and from C to D steam is being taken by the large cylinder. D corresponds to the cut-off in the large cylinder, which is the point to be found. From D to E steam is being compressed into the receiver. To avoid drop the receiver pressure at E is to be the same as the pressure at C. E is therefore known, and may be employed as the starting-point in drawing a curve EF which is the admission line of the low pressure diagram EFGHI. This line is drawn by considering at each point in the low pressure piston's stroke what is then the whole volume of the steam. The place at which EF intersects the continuous expansion curve BCG determines the proper point of cut off. The sketch (fig 31) refers to the case of a tandem receiver engine, but the process may also be applied to an engine with any assumed phase relation between the cranks. Fig 32 shows a pair of theoretical indicator diagrams determined in the same way for an engine with cranks at right angles, the high-pressure crank leading. In using the graphic method any form may be assigned to the curve of expansion. Generally this curve may be treated without serious inaccuracy as a common hyperbola, in which the pressure varies inversely as the volume.

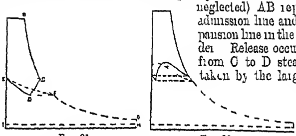

Fig 31. Fig 32.

FIGS 31 and 32.—Determination of the point of cut off in the low pressure cylinder of a compound engine.

115. If this simple relation between pressure and volume be assumed, it is practicable to find algebraically the low pressure cut-off which will give no drop, with assigned ratios of cylinder and

[1] An intermediate receiver has the thermodynamic advantage that it reduces the range of temperature in the high pressure cylinder, and so helps to prevent initial condensation of the steam. This will be made obvious by a comparison of fig 29 and fig 30. The lowest temperature reached in the high pressure cylinder is that corresponding to the pressure at D, and is materially higher in fig 30 than in fig 29.

[2] See a paper by Prof R H Smith, "On the Cut off in the Large Cylinder of Compound Engines," *The Engineer*, November 27, 1885.

receiver volumes. Taking the simplest case—that of a tandem engine, or of an engine with parallel cylinders whose pistons move together or in opposition—we may proceed thus. Since the point of cut-off to be determined depends on volume ratios we may for brevity treat the volume of the small cylinder as unity. Let R be the ratio to it of the receiver's volume, and L that of the low pressure cylinder. Let x be the required fraction of the stroke at which cut off is to occur in the large cylinder, and let p be the pressure at release from the small cylinder. As there is to be no drop, p is also the pressure in the receiver at the beginning of admission to the large cylinder. During that admission the volume changes from $1+R$ to $1-x+R+xL$, and the pressure at cut-off is therefore $\frac{p(1+R)}{1-x+R+xL}$. The steam that remains is now compressed into the receiver, from volume $1-x+R$ to volume R. Its pressure therefore rises to $\frac{p(1+R)}{1-x+R+xL}\cdot\frac{(1-x+R)}{R}$, and this, by assumption, is to be equal to p. We therefore have

$$(1+R)(1-x+R)=R(1-x+R+xL),$$

whence

$$x=(R+1)/(RL+1).$$

Thus, with R=1 and L=3, cut off should occur in the large cylinder at half stroke; with a greater cylinder ratio the cut off should be earlier.

A similar calculation[1] for a compound engine whose cranks are at right angles, and in which cut off occurs in the large cylinder before half stroke, shows that the condition of no drop is secured when

$$2R(xL-1)=1-2\sqrt{x(1-x)}.$$

In some compound engines a pair of high pressure cylinders discharge into a common receiver; in some a pair of low pressure cylinders are fed from a receiver which takes steam from one high pressure cylinder, or in some instances from two. With these arrangements the pressure in the receiver may be kept much more nearly constant than is possible with the ordinary two cylinder type.

Uniformity of effort in a compound engine.

116. An important mechanical advantage belongs to the compound engine in the fact that it avoids the extreme thrust and pull which would have to be borne by the piston-rod of a single cylinder engine working at the same power with the same initial pressure and the same ratio of expansion. If all the expansion took place in the low-pressure cylinder, the piston at the beginning of the stroke would be exposed to a thrust much greater than the sum of the thrusts on the two pistons of a compound engine in which a fair proportion of the expansion is performed in the small cylinder. Thus in the tandem engine of fig 29 the greatest sum of the thrusts will be found to amount to less than two thirds of the thrust which the large piston would be subjected to if the engine were simple. The mean thrust throughout the stroke is of course not affected by compounding; only the range of variation in the thrust is reduced. The effort on the crank-pin is consequently made more uniform, the strength of the parts may be reduced, and the friction at slides and journals is lessened. The advantage in this respect is obviously much greater when the cylinders are placed side by side, instead of tandem, and work on cranks at right angles. As a set off to its advantage in giving a more uniform effort, the compound engine has the drawback of requiring more working parts than a simple engine with one cylinder. But in many instances—as in marine engines—two cranks and two cylinders are almost indispensable, to give a tolerably uniform effort and to get over the dead points; and the comparison should then be made between a pair of simple cylinders and a pair of compounded cylinders. Another point in favour of the compound engine is that, although the whole ratio of expansion is great, there need not be a very early cut-off in either cylinder; hence the common slide valve, which is unsuited to give an early cut-off, may be used in place of a more complex arrangement. The mechanical advantage of the compound engine has long been recognized, and had much to do with its adoption in the early days of high-pressure steam.[2] Its subsequent development has been due in part to this, but probably in much greater part to the thermodynamic advantage which has been discussed above (§ 93).

Indicator diagrams.

117. Indicator diagrams taken from compound engines show that the transfer of steam from one cylinder to another is never, under the most favourable conditions, performed without loss of energy. Fig 33 shows a pair of diagrams from the two cylinders of a tandem Woolf engine, in which the steam passed as directly as possible from the small to the large cylinder. The diagrams are drawn to the same scale of *stroke* and therefore to different scales of *volume*, and the low-pressure diagram is turned round so that it may fit into the high pressure diagram. There is some drop at the high pressure release, and, apart from this, there is a loss through friction of the passages, which shows itself by the admission line to the large cylinder lying below the exhaust line from the small one.

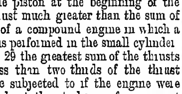

Fig 33

118. Fig 34 is a pair of diagrams taken from a compound tandem receiver engine running at 50 revolutions per minute, with cylinders 30 inches and 52 inches in diameter, and with a 6-feet stroke. The ratio of cylinder volumes is therefore 3 to 1. The capacity of the receiver is nearly $1\frac{1}{2}$ times that of the small cylinder. There is a comparatively early cut off in both cylinders, and a nearly complete absence of drop. The small cylinder, however, does more work than the large one, in the ratio of nearly 3 to 2.

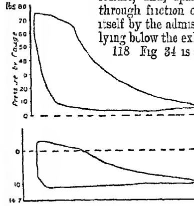

Fig 34

Combination of diagrams from compound engines.

Fig 35 shows the same pair of diagrams combined by drawing both to the same scale of volume and of pressure, and by setting out each by an amount equal to the clearance space from the line of no volume. This makes the expansion curve in each diagram represent correctly the relation of the pressure to the absolute volume of the expanding steam. The broken line is a continuous curve of *adiabatic* expansion, drawn from the point of high-pressure cut off, on the assumption that the steam then contained about 25 per cent of condensed water. If the expansion were actually adiabatic, and if there were no loss in the transfer of the steam, the expansion curves for both cylinders would fall into this line.

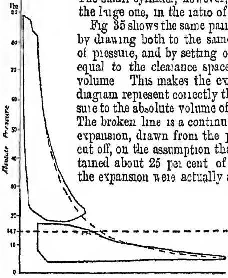

Fig 35.—Diagrams of fig 34 combined.

119. Fig 36 exhibits, in the same manner as fig 35, a set of diagrams taken by Mr Kirk from the triple expansion engines of the S S "Aberdeen." Each diagram is set out from the line of no volume by a distance which represents the clearance in the corresponding cylinder. The boiler pressure is 125 lb per square inch. The cylinders are 32 inches, 46 inches, and 70 inches in diameter, and the stroke is $4\frac{1}{2}$ feet. The cranks make 120° with each other. The means of the diagrams for the two ends of each cylinder have been used in drawing this and the next figure, a practice which should be followed in drawing combined diagrams of the kind here exemplified.

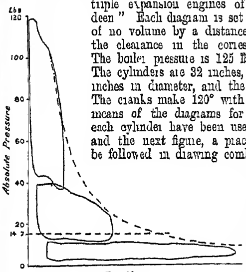

Fig 36

120. Fig 37 shows in the same way a set of diagrams taken by Mr Brock from the *quadruple* expansion engines of the S S "Lohara" (by Messrs Denny & Co). Here the boiler pressure was 154 lb by gauge, or 169 lb absolute, the cylinders were 24 inches, 34 inches, 48 inches, and 68 inches in diameter, the stroke was 4 feet, and the number of revolutions 65 per minute.

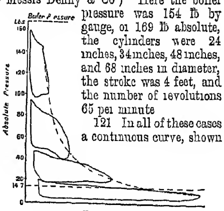

Fig 37

121. In all of these cases a continuous curve, shown by a broken line, has been drawn to represent the result of adiabatic expansion, on the same assumption as before—that the steam contains about 25 per cent of water at the point of cut off in the

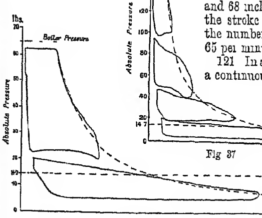

Fig 38

[1] Examples of calculations dealing with particular arrangements of two and three cylinder compound engines will be found in an Appendix to Mr R Sennett's *Treatise on the Marine Steam Engine*.

[2] See a paper by Dr W Pole, "On the Double Cylinder Expansive Engine," *Proc Inst M E*, 1862.

first cylinder. The equation to the curve may then be taken as $PV^{\frac{10}{9}} = \text{constant}$ (§ 67). In the absence of data regarding the wetness of the steam this assumption may be considered fair.

122. Lastly, fig. 38 shows a pair of diagrams, treated in the same manner, for a two-cylinder compound engine with cranks at right angles to each other, the high-pressure crank being 90° in advance. During the back stroke of the high-pressure piston there is at first compression into the receiver until the large cylinder opens; the high-pressure diagram consequently takes a peculiar form, which should be compared with the diagram already given for a tandem engine (§ 118). In this example there is a considerable amount of drop and also of loss between the two cylinders.

VII. THE PRODUCTION OF STEAM.—BOILERS.

Furnace efficiency. 123. The first step in the production of steam is to convert the potential energy of fuel into actual heat; the second step is to transfer the heat to water in the boiler. The efficiency of furnace and boiler is the ratio which the amount of heat taken up by the water bears to the whole potential energy of the fuel. In good boilers this efficiency is about 0.7. The loss is due partly to incomplete combustion of the fuel and partly to incomplete transfer of heat from the products of combustion to the boiler water. Under the first head may be classed—(1) waste of fuel in the solid state by bad stoking, and (2) waste of fuel in the gaseous and smoky states by imperfect combustion. Under the second head are comprised—(1) waste by external radiation and conduction, and (2) waste by heat contained in the hot gases which escape by the chimney, due (*a*) to their still high temperature and (*b*) to the fact that they contain as one of the products of combustion steam gas which passes away uncondensed. Loss of heat by the hot gases is the most important source of waste. Not only are the actual products of combustion rejected at a high temperature, but along with them goes the nitrogen of the air whose oxygen has been used, and also a quantity of additional air which is needed to dilute the products in order that combustion may be fairly complete. Roughly speaking, about 12 lb of air are required to supply oxygen enough for the combustion of 1 lb of coal. Over and above this quantity, about 12 lb more generally pass through the furnace as air of dilution. In furnaces with forced draught, in which the consumption of coal per square foot of grate surface is much more rapid, the air of dilution may be reduced to half or less than half of this quantity, though to some extent at the expense of completeness in the combustion.

Heating surface. 124. The extent to which heat is taken from the hot gases depends on the *heating surface* through which heat passes into the water. The heating surface is made up of the surface of the furnace or combustion chamber, so far as that is brought into contact with the water, and of the flues or tubes through which the hot gases pass on their way to the chimney. Its efficiency depends on the conductivity of the metal, on the difference in temperature between the gases on one side and the water on the other, and on the freedom with which steam, when formed, can escape from the surface. Differences in specific conductivity and in thickness of metal affect the result less than might be expected, on account of the resistance which is offered to the passage of heat through the film of scale and also through the film of water vapour which forms on the metallic surface.

By extending the heating surface sufficiently the hot gases may be deprived of heat to an extent which is only limited by the temperature of the boiler water. This temperature, however, need not form a limit, for after leaving the boiler the gases may be further cooled by being brought into contact with a vessel termed a feed-water heater, through which the feed-water passes on its way to the boiler. Even with a feed water heater, however, the temperature of the hot gases is never, in practice, reduced so low as that of the boiler.

Draught. 125. In nearly all land engines and most marine engines the draught is produced by means of a chimney, which acts in virtue of the column of air within it being specifically lighter than the air outside, so that the pressure within the chimney at its base is less than the atmospheric pressure at the same level outside. The composition of the chimney gases is such that they are heavier than air at the same temperature, and to make them sufficiently lighter to cause a draught they must retain a certain considerable portion of their heat. On the other hand, if they are left too hot the mass of air drawn through the furnace is actually diminished, since then the chimney gases are so much expanded that the increased volume of the draught does not compensate for its diminished density. With a given chimney and furnace the maximum draught is obtained when the gases escape at a temperature about that of melting lead; by making the chimney more capacious a lower temperature will suffice to give the same draught, and this will of course increase the efficiency of the boiler.

126. In place of using a chimney draught depending merely on the temperature of the rejected hot gases, the air required for combustion and dilution may be forced through the furnace either by producing a partial vacuum in the chimney or by supplying air to the grate at a pressure higher than that of the atmosphere. In locomotives, for example, a partial vacuum is produced in the chimney by means of a blast of exhaust steam from the engine; and in many naval and a few mercantile steamers a forced draught is produced by having a closed stokehole or a closed ashpit, which is supplied with air at a pressure above that of the atmosphere by the use of a blowing fan.

If heat were thoroughly extracted from the products of combustion, a forced draught would be more efficient, from the thermodynamic point of view, than a chimney draught, for a chimney is in fact an extremely inefficient heat engine, and requires a very large amount of heat to be expended in order to effect the comparatively trifling work of maintaining the draught. But where forced draught has been substituted for chimney draught this has hitherto been done for the purpose of increasing not the efficiency but the *power* of boilers. The motive has been to burn more coal per square foot of grate surface and so to evaporate more water with a boiler of given weight. This is incompatible with very high efficiency. When more coal is burnt by forcing the draught it is true that the products of combustion have a higher temperature (since less air is required for dilution) and the effectiveness of the heating surface is therefore increased. But the heating surface has more hot gas to deal with, and the result is that the boiler is less efficient than when the draught is not forced. The same efficiency could be secured, with forced draught, by increasing the heating surface to a sufficient extent; and a still greater efficiency could be realized if the heating surface were still further enlarged so that the gases left the flues at a temperature lower than would be needful if the draught depended on the lightness of the chimney's contents. The most efficient boiler would be one in which the draught was forced by mechanical means, and the gases were then cooled as far as possible by contact with a very extensive heating surface, first in the boiler itself and then in a feed water heater. None of the forced draught boilers that have hitherto been introduced have a heating surface so large as to make them more efficient than good chimney draught boilers (in which the rate of combustion is much slower), although the heating surface bears a much larger ratio to the grate area than is usual with chimney draughts.

Boilers for stationary engines. 127. Most modern boilers are internally fired; that is to say, the furnaces are more or less completely enclosed within the boiler. Externally fired boilers are for the most part much less efficient than internally fired boilers; they are, however, used to a considerable extent where fuel is specially cheap or where the waste heat of other furnaces is to be utilized. Their usual form is that of a horizontal cylinder with convex ends, the strength both of the main shell and the ends is derived from their curvature, and no

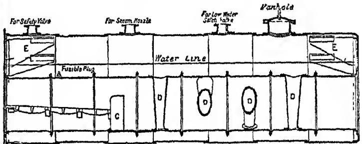

FIG. 39.—Cornish Boiler: longitudinal section.

staying is necessary. The heating surface is entirely external and is of very limited extent.

Cornish and Lancashire boilers. In large stationary boilers the forms known as the "Lancashire" (or double flue) and the "Cornish" (or single flue) are most common. Figs. 39 and 40 show in section a Cornish boiler by Messrs Galloway, and fig. 41 a Lancashire boiler by the same makers. In both the shell is a round horizontal cylinder with flat ends. In the Cornish boiler there is one internal flue, at the front end of which is the furnace. The hot gases pass through the flue to the back; they then return to the front end by two external side flues

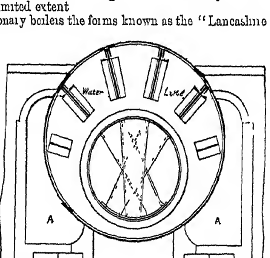

FIG. 40.—Cornish Boiler: transverse section, showing flues.

(A, A, fig 40), and finally pass to the back again by an underneath flue B The arrangement in the Lancashire boiler is the same, except that there are two internal flues, each with its own furnace The shell is made up of rings of riveted plates, larger and smaller in diameter alternately to allow the circumferential seams to be made without bending the edges The flue is made up of a series of welded rings, joined to each other by a flanged joint with a stiffening ring This form of joint was introduced by Mr Adamson to stiffen the flue against collapse under external pressure Other joints, designed with the same object, are shown in figs 42 and 43 The grate is made up of firebars,

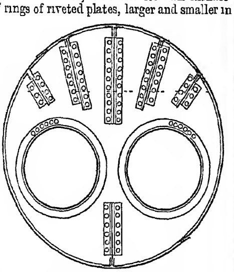

FIG 41 —Lancashire Boiler Transverse Section

sloping down towards the back, where they terminate at the "bridge" of fire brick (C, fig 39) Beyond the bridge the flue is crossed by a number of tapered "Galloway" tubes D, D, which increase the heating surface, promote circulation of the water, and stiffen the flue The end plates are strengthened by gusset stays

FIGS 42 and 43 —Joints for Furnace Tubes

E, E, riveted to them and to the circumference of the shell by means of angle-irons The gusset stays do not extend so far in as to the circumference of the flue (fig 40), in order that the end plates may retain enough flexibility to allow the flue to expand and contract under change of temperature To provide for unequal expansion is one of the most important points in the design of boilers, when it is neglected the boiler is subjected to a racking action which induces leakage at joints and tends to rupture the plates For this reason the flue is attached to the boiler shell at the ends only, so that it may be free to take an upward camber in consequence of the greater heating of the upper side

Mild steel is now very generally used for boiler plates, being superior even to the best Yorkshire iron in the qualities of ductility and tensile strength The following particulars refer to the Lancashire boiler of fig 41, which may be taken as representative of a large number of stationary boilers

tails Lan -shire -ler

128 The shell is 28 feet long and 7 feet in diameter, and is made up of 9 rings, each of two semi cylindrical plates The shell plates are ⅝ inch thick, their edges are planed and fullered, and the rivet holes are drilled The longitudinal seams, which break joint from ring to ring, are lap-joints double-riveted, the circular seams are single-riveted Each end plate is a solid piece of steel ½ inch thick, the front plate is attached to the shell by riveting to an angle ring, the back plate is flanged The flues are each 2 feet 9½ inches in diameter, made up of rings of steel ⅜ inch thick, the longitudinal joints are welded and the circular joints are flanged and strengthened with stiffening rings The flues are tapered somewhat at the back end to facilitate expansion, and are attached to the end plates by welded angle-rings Each flue contains 5 Galloway tubes, tapering from 10½ inches diameter at top to 5½ inches at bottom On the top of the boiler is the manhole, covered with a cast-iron plate, also a nozzle for the steam pipe and two others for safety-valves One of the safety valves is connected with a float so that it opens if the water-level becomes too low At the bottom, in front, is another nozzle for the blow out tap, and

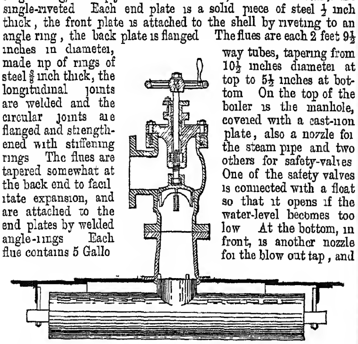

FIG 44 —Anti Priming Pipe and Stop Valve

in the front plate below the flues is another manhole Feed water is supplied by a pipe which enters through the front plate on one side, near the top of the water, and extends for a considerable distance along the boiler, distributing the water by holes throughout the length. A pipe at the same level on the other side serves to collect scum The fire doors are provided with sliding shutters by means of which the amount of air admitted above

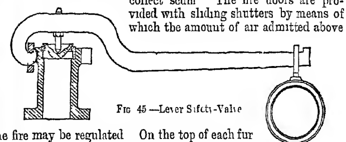

FIG 45 —Lever Safety-Valve

the fire may be regulated On the top of each furnace is fitted a fusible plug which melts if the furnace crown becomes overheated No separate steam dome is used, the steam is collected by an "anti priming" pipe shown in fig 44, which also illustrates the stop-valve by which the delivery of steam from the boiler is started or stopped at will On the front plate are a pair of glass gauge tubes for showing the water-level, and a Bourdon pressure gauge This last important fitting consists of a bent tube of oval section, one end of which is closed and free to move while the other is open to the steam and is fixed The pressure within the tube tends to straighten it, and the extent

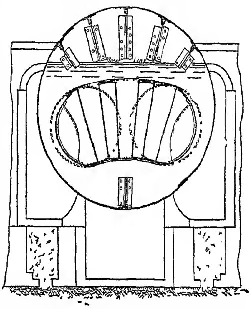

FIG 46 —Galloway Boiler Section beyond the Bridge

to which this takes place is shown by a pointer which travels over a circular dial A common lever safety valve is shown in fig 45 In other forms the valve is kept down by a weight directly applied to it, or by means of springs Spring safety valves are liable to the objection that when the valve opens the load on it increases, to remedy this, forms have been proposed in which the spring acts through a bent lever in such a way that when the strain on it increases the leverage at which it acts is reduced If the spring is of reasonable length, however, the objection is not serious

129 A modification of the Lancashire type—the "Galloway" boiler—is shown in sectional elevation in fig 46 In it the two flues are joined beyond the bridge into a single flue, of the form shown in the figure, which is traversed by numerous Galloway tubes and is also fitted with water-pockets at its sides Galloway boiler

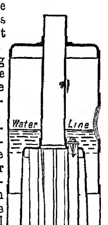

FIG 47 —Vertical Boiler with Vertical Water Tubes

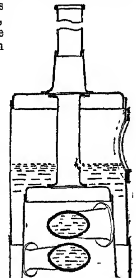

FIG 48 —Vertical Boiler with Horizontal Water Tubes

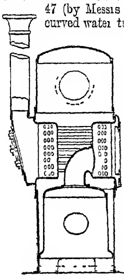
Multi-tubular boilers.

130 In other types of boiler an extensive heating surface is obtained by the use of a large number of small tubes through which the hot gases pass This construction is universal in locomotive and marine boilers It is applied in some instances to boilers of the ordinary cylindrical form by making small tubes take the place of that part of the flue or flues which lies behind the bridge, or by using small tubes as channels through which the gases return from back to front after passing through the main flue Another form of tubular boiler is an externally fired horizontal cylinder fitted with tubes which carry the hot gases from the back to the front

Vertical boilers

131 Vertical boilers are extensively used in connexion with small engines Examples are shown in figs 47–49 Fig 48 is an ordinary vertical boiler filled with cross tubes of the Galloway type Fig 47 (by Messrs Davey, Paxman, & Co) is a boiler with curved water tubes, each of which has fitted in the top a loose cap whose function is to deflect the stream of water which circulates up the tubes Fig 49 is a form of multitubular boiler by the same makers, in which the hot gases escape at the side after passing from the smoke box through horizontal tubes grouped in circular arcs In all these boilers the grate is at the foot, and the fire-door is at a mouthpiece in the side of the boiler near the base In other forms of vertical boiler the heating surface is increased by water tubes (fig 50) which hang from the crown of the fire-box, closed at the lower end but fitted internally with smaller tubes which are open at the bottom Water circulates down the inner tubes and up between them and the outer Tubes of this kind (called Field tubes) are used in fire engine boilers and in other cases where it is necessary to get up steam with the least possible delay Vertical boilers of large size are sometimes used for utilizing the waste heat of iron furnaces



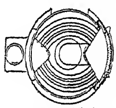


Fig 49 —Vertical Boiler Tubular Form

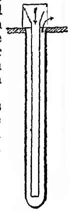

Fig 50 —Field Tube

Sectional or tubulous boilers

132 A great variety of boilers have been designed in which the firing is external, and the water space consists of groups of tubes or other small sections whose outer surface is exposed to heat Boilers of this type are called sectional or tubulous boilers, in distinction to tubular boilers, or boilers with tubes in which the hot gases circulate A successful example of the tubulous or sectional type is the Babcock & Wilcox water-tube boiler, which consists of a series of inclined welded tubes up which water circulates These are joined at their ends by cast-iron connecting boxes to one another and to a horizontal drum on the top in which the mixture of steam and water which rises from the tube undergoes separation At the lowest point of the boiler is another drum for the collection of sediment Root's boiler is another in which water is heated by circulating through inclined tubes exposed to the fire, it differs from the above form chiefly in having the water-level below the top of the tube Harrison's boiler is a group of small globular vessels of cast iron strung like beads on rods which tie them together Sectional boilers may be constructed without difficulty to bear pressures greatly in excess of those for which other types are suited Mr Perkins has employed a tubulous boiler to deliver steam at a pressure of 500 lb per square inch [1] The Herreshof boiler is a continuous coil of tube, arranged as a dome over the fire Feed-water is pumped slowly through the coil, and turns to steam before it reaches the end

Locomotive boilers

133 The locomotive boiler consists of a nearly rectangular fire-box, enclosed above and on the sides by water, and a cylindrical part called the barrel extending horizontally from the fire-box to the front part of the locomotive and filled with numerous tubes Figs 51 and 52 show in longitudinal and transverse section a boiler of the London and North Western Railway, which may be taken as typical of modern English practice

The barrel is 10 feet long and a little more than 4 feet in diameter, and is made up of three rings of steel plates, $\frac{11}{16}$ inch thick, arranged telescopically It contains 198 brass tubes, each $1\frac{7}{8}$ inches in external diameter The front tube plate in which the tubes terminate is of steel $\frac{3}{4}$ inch thick, it is stayed to the back tube plate by the tubes themselves, and the upper part of the front tube plate is also tied by longitudinal rods to the back end plate The fire-box is of copper $\frac{1}{2}$ inch thick It is nearly rectangular, with a horizontal grate (A grate sloping down in front is often preferred) Round its sides, front, and back (except where the fire door interrupts) is a water space about 3 inches wide, which narrows slightly towards the bottom The flat sides of the fire box are tied to the flat sides of the shell by copper stay bolts, 4 inches apart, which are secured by screwing them into both plates and riveting over the ends The roof of the fire box is stiffened by a number of girders on the top, to which the plates are secured by short bolts The girders are themselves hung from the top of the shell above them by slings which are secured to angle irons riveted

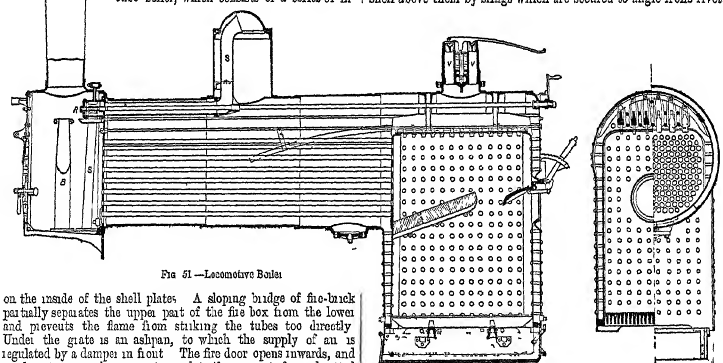

Fig 51 —Locomotive Boiler

Fig 52

on the inside of the shell plates A sloping bridge of fire-brick partially separates the upper part of the fire box from the lower and prevents the flame from striking the tubes too directly Under the grate is an ashpan, to which the supply of air is regulated by a damper in front The fire door opens inwards, and can be set more or less open, to regulate the amount of air admitted above the fire On top of the barrel is a steam dome, from which the steam supply is taken through a pipe S traversing the forward part of the steam space and passing down to the valve-chest through the smoke box The stop valve or "regulator" R is situated in the smoke box, and is worked by a rod through the boiler from the cab at the back Above the fire box end of the shell are a pair of Ramsbottom safety valves, V, V—two valves pressed down by a single spring attached to the middle of a cross bar, which is prolonged to form a hand lever by which the valves may be lifted In front of the forward tube plate is the smoke box, containing the blast pipe B by which the exhaust steam is used to produce a partial vacuum and so force a draught through the furnace

134 Instead of stiffening the fire-box roof by the use of girder stays, the plan is sometimes followed of staying it directly to the shell above The outer shell above the fire-box is generally cylindrical, but to facilitate this method of staying it is sometimes made flat This construction is not unusual in American locomotive boilers, another feature of which is that the grate is made much larger than in English practice, for the purpose of burning anthracite coal An extreme instance is furnished by the Wooton engines of the Philadelphia and Reading Railroad, which burn small coal of poor quality in a fire box $9\frac{1}{2}$ feet long by 8 feet wide, extending over the trailing wheels of the engine In some cases the fire-box is divided by a sloping partition of plates with water between, which crosses the fire-box diagonally from front to back and has in its centre an opening resembling a fire door mouthpiece to allow the products of combustion to pass In others the fire bridge is supported by water tubes, and water tubes are also used as grate-bars This is done rather to promote circulation of the water than to give heating surface The practice of American and English locomotive engineers differs widely as regards the materials of construction American shells are of mild steel, English shells gene-

[1] *Proc Inst Mech Eng*, 1877 See also a paper by Mr Flannery, "On High-Pressure Steam Boilers," *Min Proc Inst C E*, 1878

rally of mild steel but often of wrought iron In English practice the fire boxes are of copper and the tubes of brass, in America the fire-boxes are of mild steel and the tubes of wrought-iron [1]

The locomotive type of boiler is used for stationary engines of the portable, semi-portable, and semi fixed types, and also to a limited extent for marine engines in cases were lightness is of special advantage

Marine boilers

135 So long as marine engines used steam of a pressure less than about 35 lb per square inch the marine boiler was generally a box with flat sides, elaborately stayed, with a row of internal furnaces near the bottom opening into a spacious combustion-chamber enclosed within the boiler at the back, and a set of return tubes leading from the upper part of the chamber to the front of the boiler, where the products of combustion entered the uptake and passed off to the funnel The use of higher pressures has made this form entirely obsolete The normal marine boiler is now a short circular horizontal cylinder of steel with flat ends, with internal furnaces in cylindrical flues, internal combustion-

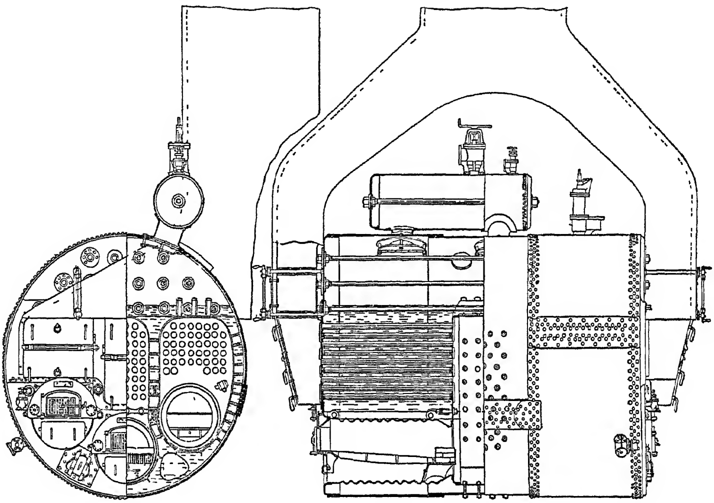

Fig 53 Fig 54

FIGS 53, 54 —Double Ended Marine Boiler.

chambers, and return tubes above the flues In one variety, called the double ended boiler, there are furnaces at both ends of the shell, each pair leading to a combustion-chamber in the centre that is common to both, or to separate central chambers with a water space between them

Details of double-ended marine boiler

Figs 53 and 54 show with some completeness a double ended marine boiler of the most modern construction for high-pressure steam At each end there are three furnaces in flues made of welded corrugated steel plates The use of corrugated plates for flues, introduced by Mr Fox, makes thin flues able to resist collapse, and allows the flues to accommodate themselves easily to changes of temperature One combustion-chamber is common to each pair of furnaces It is strengthened on the top by girder stays and on the sides by stay-bolts to the neighbouring chamber and to the shell The tubes are of iron, and a certain number of them are fitted with nuts so that they serve as stays between the tube-plate of the combustion-chamber and the front of the boiler The upper part of the front plate is tied to the opposite end of the boiler by long stays The uptakes from both ends converge to the funnel base above the centre of the boiler's length The boiler shown is one of a pair, which lie side by side in the vessel, the uptake at each end being common to both Each boiler has a steam-dome, from which the steam-pipe leads to the engine, this consists of a small cylindrical vessel, with flat ends tied together by a central stay Short pipes connect the dome near each end with the steam space of the main shell The boilers of figs 53 and 54, which are by Messrs Gourlay Brothers of Dundee, work at a pressure of 165 lb per square inch above the atmosphere, and are used with triple expansion engines The shell is $12\frac{1}{4}$ feet in diameter, and $16\frac{1}{2}$ feet long The plates are of mild steel $1\frac{1}{8}$ inches thick round the shell and 1 inch in the ends The tube plates are $\frac{7}{8}$ inch and $\frac{15}{16}$ inch thick, and the corrugated flues $\frac{1}{2}$ inch The longitudinal seams are treble-riveted, with inside and outside covering plates The circumferential seams are lap joints double-riveted There are 127 tubes at each end, 46 of which are stay-tubes The tubes are of iron, $3\frac{1}{4}$ inches in external diameter Above these are 18 longitudinal steel stays $2\frac{3}{4}$ inches in diameter The steam-dome is a cylinder $2\frac{1}{2}$ feet in diameter and 8 feet long, stayed by a central $3\frac{1}{2}$-inch rod of steel The short fire box stays are also of steel $1\frac{1}{2}$ inches in diameter, of $7\frac{3}{4}$ inches pitch, and are secured by nuts and washers at both ends The central combustion-chamber has a round and unstayed roof The top of each side combustion-chamber is stayed by three steel girders $8\frac{5}{8}$ inches $\times\ 2\frac{1}{4}$ inches in section, secured by four bolts to the roof-plate below A single-ended marine boiler by the same makers is shown in fig 55 Boilers of this class are in some instances set athwartship instead of longitudinally, and bevelled on the bottom, at the back, to accommodate them to the shape of the hull A modification of the cylindrical form is occasionally used, in which the section is an oval, with round top and bottom and flat sides The combustion chambers are sometimes made with rounded tops, which are tied to the back plate by gusset-stays and angle-irons In naval practice the tubes are frequently of Muntz metal in place of iron Another form of boiler, used to a considerable extent in the British navy, is a long horizontal cylinder with two

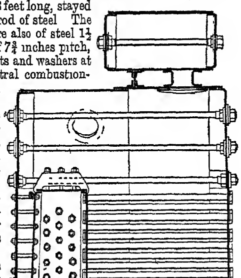

FIG 55 —Single-Ended Marine Boiler

Navy type

[1] See a paper by Mr Fernie, *Min Proc Inst C E*, 1883

internal furnaces opening into a large combustion chamber about the middle of the length From this a set of tubes distributed over nearly the whole water space extend to the back, where the uptake is situated

Locomotive type of marine boiler

136 The locomotive type of boiler has been successfully adapted to marine use by Mr Thornycroft and others especially for torpedo boats This form gives much greater heating surface than others in proportion to its weight, and allows, especially when worked with forced draught, a large amount of power to be got from a small boiler It is probable that, if any further rise is to occur in the steam pressure used in marine engines, comparable to that which has occurred during the last two or three years, the present normal marine boiler will give place to a form more nearly resembling the locomotive type

Feeding boilers Injector.

137 Boilers are usually fed either by a feed pump driven by the engine, or by a distinct auxiliary engine called a "donkey," or by an injector The *injector*, invented by the late M Giffard, and now very generally used on locomotive and other boilers, is illustrated in fig 56 Steam enters from the boiler at A and blows through an annular orifice B, the size of which is regulated by the handle C The feed-water flows in at D, and meeting the steam at B causes it to condense This produces a vacuum at B, and consequently the water rushes in with great velocity, and streams down through the combining nozzle I, its velocity being augmented by the impact of steam on the back of the column In the lower part of the nozzle E the stream expands, it therefore loses velocity, and, by a well-known hydrodynamic principle, gains pressure, until at the bottom its pressure is so great that it enters the boiler through a check valve which opens only in the direction of the stream The escape orifice F and the overflow pipe G allow the injector to start into action, by providing a channel through which steam and water may escape before the stream acquires enough energy to force its way into the boiler The opening for admitting water between D and B is regulated by the wheel H The *exhaust-steam injector* works by steam from the exhaust of non-condensing engines, instead of boiler steam The steam orifice is then larger in proportion to the other parts, and the steam supply more liberal In *self starting injectors* an arrangement is provided by which overflow will take place freely until the injector starts into action and then the openings are automatically adjusted to suit delivery into the boiler One plan of doing this is to make the combining nozzle under the steam orifice in a piece which is free to slide in the outer casing Until the injector starts it lies at some distance from the steam orifice, and allows free overflow, but when the vacuum forms it rises, in consequence of pressure at the base In self-adjusting injectors this rise of the combining nozzle is made use of to contract the water-way round the steam orifice In another form of self starting injector one side of the combining nozzle is in the form of a hinged flap, opening backwards to allow overflow, but closing up when a vacuum is formed and the injector starts into action [1]

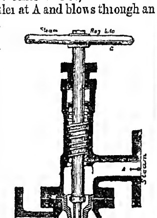

Fig 56 —Giffard's Injector

Hydrokineter

Weir's *hydrokineter* for large marine boilers is another apparatus in which the principle of the injector is made use of, with the object of promoting circulation of the water during the time steam is being raised It consists of a series of nozzles, with water-inlets between them, through which water is drawn by means of a central jet of steam supplied from a donkey boiler

Feed-water heaters

138 In stationary engine boilers the feed water is frequently heated by the products of combustion before these reach the chimney, in what is virtually an extension of the boiler itself Green's economizer is a contrivance for this purpose, in which the water passes through tubes whose outer surface is exposed to the hot gases and kept clear of deposited soot by the continuous action of a mechanical scraper In locomotives and other non condensing engines a portion of the exhaust steam is frequently made use of to heat the feed water When an exhaust steam injector is employed it serves the purpose of a feed water heater as well as that of a feed pump Besides increasing the efficiency of the boiler by utilizing what would otherwise be waste heat, a feed water heater has the advantage that by raising the temperature of the water it removes air, and also, in the case of hard water, causes lime and other substances held in solution to be deposited in the heater instead of being carried into the boiler, where they would form scale In Weir's feed heater for marine engines the temperature of the feed water is raised to about 200° Fahr by injecting steam from the intermediate receiver

Separator Steam trap

139 In stationary and marine boilers the steam, after leaving the boiler, is frequently taken through a *separator*, the function of which is to separate the dry steam from particles of water held in suspension Steam is led round a sharp corner, and the water particles thrown off by centrifugal force collect in a *trap* below, from which they are discharged by a pipe which is kept open so long as the trap contains water, but is closed by a valve at the foot when the trap is empty Traps are also fitted in many cases to steam pipes for the purpose of returning condensed water to the boiler

Use of zinc in boilers

140 To prevent corrosion in boilers it is very usual to introduce blocks of zinc in metallic connexion with the shell These are set in the water space, preferably at places where corrosion has been found specially liable to occur Their function is to set up a galvanic action, in which zinc plays the part of the negative element, and is dissolved while the metal of the shell is kept electro positive Otherwise there would be a tendency for difference of electric quality between different parts of the shell to set up galvanic actions between the parts themselves, by which some parts, being negative to others, would be attacked The zinc raises the potential of the whole shell enough to make all parts positive

Forced draught

141 Allusion has already been made to the system which is universal in locomotive boilers of forcing the draught by a blast of exhaust steam in the chimney A jet of boiler steam is occasionally used in marine furnaces for the same purpose, but of late years the system which has found most favour is to box in the stokehole and keep the air in it at a pressure of from 1 to 3 inches of water by the use of blowing fans This system has been applied largely in naval practice, with the result that the power of the boiler is increased in the ratio of about 3 to 2, or even more, as compared with its power under chimney draught The efficiency of the boiler is, in general, slightly but not very materially reduced An ordinary marine boiler burns 16 to 20 ℔ of coal per hour per square foot of grate with natural draught, and 30 ℔ or more with forced draught In torpedo-boat boilers of the locomotive type the consumption has in some cases been forced to more than 100 ℔

In Mr Howden's system of forced draught the stokehole is open, and air is supplied by a blowing fan to a reservoir formed by enclosing the ashpit and also to another reservoir from which it gets access to the grate above and through the fire door On its way to the reservoir the air is heated by passing across a part of the uptake in which the hot gases from the furnace are led through tubes This method of restoring to the furnace what would otherwise be waste heat forms an interesting alternative to the method of restoring heat to the boiler by passing the hot gases through a feed-water heater, it is in fact an application to boiler furnaces of the regenerative principle alluded to in chap II [2]

Mechanical stokers

142 Many appliances have been devised for the mechanical supply of coal to boiler furnaces, but these have hitherto taken the place of hand-firing to only a very limited extent In Juckes's furnace the fire-bars are in short lengths, jointed by pins to form a continuous chain or web, which rests on rollers and is caused to travel slowly in the direction of the furnace's length by pin wheels round which the web is carried at the front and back Coal is allowed to drop continually on the travelling grate from a hopper in front of the furnace A more usual form of mechanical stoker is a reciprocating shovel or ram, supplied from a coal hopper, which throws or pushes a small quantity of coal into the fire at each stroke Along with this devices are employed for making the grate self cleansing, by giving alternate fire bars a rocking or sliding motion through a limited range

Dust fuel.

In Mr Crampton's dust-fuel furnace the coal is ground to powder and fed by rollers into a pipe from which it is blown into the furnace by an air blast The mixture of fuel and air is so intimate that the excess of air required for dilution is only one fifth of the amount required for combustion [3] A similar advantage attends the use of gaseous fuel, and of liquid fuel that is blown into the furnace in the form of spray

Liquid fuel

143 The use of liquid fuel for boilers has of late acquired considerable importance in connexion with the discovery of crude petroleum, in large quantity, at Baku on the Caspian Sea The petroleum refuse which is left after distilling paraffin from the crude oil forms an exceedingly cheap fuel, with a calorific value per ℔ about one third greater than that of coal It has now superseded coal in the steamers of the Caspian, and has been largely employed for locomotives in the south eastern part of Russia The oil is injected in the form of spray near the foot of the fire box by a steam jet arranged in such a way that air will be drawn into the furnace along with the petroleum In the arrangement for burning petroleum used in Russian locomotives by Mr T Urquhart the flame impinges on a structure of fire brick, built in the fire-box

[1] See papers in *Proc Inst Mech Eng*, 1860, 1866, 1884

[2] The methods and results of these systems of forcing draught are described in papers read before the Institution of Naval Architects, April 1886

[3] *Proc Inst Mech Eng*, 1869

with numerous openings to allow the products of combustion to diffuse themselves throughout the combustion chamber This guards against too intense action on the metallic surfaces, and at the same time serves as a reservoir of heat to rekindle the flame if combustion is intermittent In getting up steam an auxiliary boiler is used to supply the jet [1]

VIII THE DISTRIBUTION OF STEAM —VALVES AND VALVE MOTIONS

Slide-valve

144 In early steam engines the distribution of steam was effected by means of conical valves, worked by tappets from a rod which hung from the beam The slide-valve, the invention of which in the form now known as the long D slide is credited to Murdoch, an assistant of Watt, came into general use with the introduction of locomotives, and is now employed, in one or other of many forms, in the great majority of engines

The common or locomotive slide valve is illustrated in fig 57 The seat, or surface on which the valve slides, is a plane surface formed on or fixed to the side of the cylinder, with three ports or openings, which extend across the greater part of the cylinder's width

FIG 57 —Common Slide Valve

The central opening is the exhaust port through which the steam escapes, the others, or steam ports, which are narrower, lead to the two ends of the cylinder respectively The valve is a box-shaped cover which slides over the seat, and the whole is enclosed in a chamber called the valve-chest, to which steam from the boiler is admitted When the valve moves a sufficient distance to either side of the central position, steam enters one end of the cylinder from the valve-chest and escapes from the other end of the cylinder through the cavity of the valve into the exhaust-port

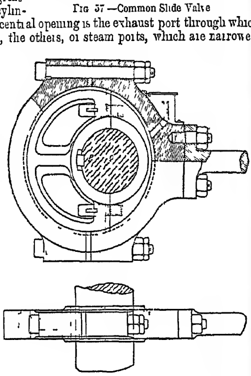

FIG 58 —Eccentric

The valve is generally moved by an eccentric on the engine-shaft (fig 58), which is mechanically equivalent to a crank whose radius is equal to the eccentricity, or distance of O, the centre of the shaft, from P, the centre of the eccentric sheave The sheave is encircled by a strap forming the end of the eccentric rod, and the rod is connected by a pin-joint to the valve-rod, which comes out of the valve-chest through a steam-tight stuffing box The eccentric rod is generally so long that the motion of the valve is sensibly the same as that which it would receive were the rod infinitely long Thus if a circle (fig 59) be drawn to represent the path of the eccentric centre during a revolution of the engine, and a perpendicular PM be drawn from any point P on a diameter AB, the distance CM is the displacement of the valve from its middle position at the time when the eccentric centre is at P AB is the whole travel of the valve

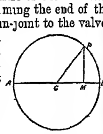

Fig 59

Lap and lead

145 If the valve when in its middle position did not overlap the steam ports (fig 60), any movement to the right or the left would admit steam, and the admission would continue until the valve had returned to its middle position, or, in other words, for half a revolution of the engine Such a valve would not serve for expansive working, and as regards the relative position of the crank and eccentric it would have to be set so that its middle position coincided with the extreme position of the piston, in other words, the eccentric radius would make a right angle with the crank Expansive working, however, becomes possible when we give the valve what is called "lap," by making it project over the edges of the steam ports, as in fig 61, where o is the "outside lap" and i is the "inside lap" Admission of steam (to either side) then begins only when the displacement of the valve from its middle position exceeds the amount of the outside lap, and continues only until the valve has returned to the same distance from its middle position Further, exhaust begins only when the valve has moved past the middle by a distance equal to i, and continues until the valve has again returned to a distance i from its middle position

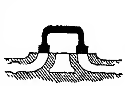

FIG 60 —Slide Valve without Lap

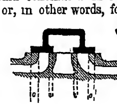

FIG 61 —Slide Valve with Lap

Thus on the diagram of the eccentric's travel (fig 62) we find, by setting off o and i on the two sides of the centre, the positions a, b, c, and d of the eccentric radius at which the four events of admission, cut off, release, and compression occur for one side of the piston As to the other side of the piston, it is only necessary to set off o to the right and i to the left of the centre, but for the sake of clearness we may confine our attention to one of the two sides Of the whole revolution, the part from a to b is the arc of steam admission, from b to c is the arc of expansion, from c to d the arc of exhaust, and from d to a the arc of compression

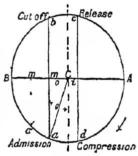

Fig 62

The relation of these, however, to the piston's motion is still undefined If the eccentric were set in advance of the crank by an angle equal to ACa, the opening of the valve would be coincident with the beginning of the piston's stroke It is, however, desirable, in order to allow the steam free entry, that the valve be already some way open when the piston stroke begins, and thus the eccentric may be set to have a position Ca' at the beginning of the stroke In that case the valve is open at the beginning of the stroke to the extent mm', which is called the "lead" The amount by which the angle between Ca' (the eccentric) and CA (the crank) exceeds a right angle is called the *angular advance*, this being the angle by which the eccentric is set in advance of the position it would occupy if the primitive arrangement without lap were adopted The quantities lap, lead, and angular advance (θ) are connected by the equation

$$\text{outside lap} + \text{lead} = \text{half travel} \times \cos\theta$$

An effect of lead is to cause *preadmission*, that is to say, admission before the end of the back stroke, which, together with the compression of steam left in the cylinder when the exhaust port closes, produces the mechanical effect of "cushioning," to which reference has already been made

Graphic method of finding the distribution of steam

To examine the distribution of steam throughout the piston's stroke, we may now draw a circle to represent the path of the crank pin (fig 63, where the dotted lines

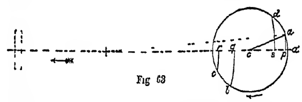

Fig 63

have been added to show the assumed configuration of piston, connecting rod, and crank) and transfer to it from the former diagram the angular positions a, b, c, and d at which the four events occur To facilitate this transfer the diagrams of eccentric path and of crank-pin path may by a suitable choice of scales be drawn of the same actual size Then by projecting these points on a diameter which represents the piston's path, by circular arcs drawn with a radius equal to the length of the connecting rod, we find p, the position of the piston at which admission occurs during the back stroke, also q and r, the position at cut off and release, during the stroke which takes place in the direction of the arrow, and s, the point at which compression begins It is obviously unnecessary to draw the two circles of figs 62 and 63 separately, the single diagram (fig 64) contains the solution of the steam distribution with a slide-valve whose laps, travel, and angular advance are known, the same circle serving, on two scales, to show the motion of the crank and of the eccentric

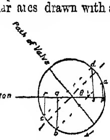

Fig 64

Oval diagram.

146 A method of representing graphically the relations of valve and piston motion, sometimes convenient in dealing with valve-gears of a more complex character than the single eccentric, is to set off the valve's and the piston's simultaneous displacement at right angles to each other, as in fig 65, the valve's motion being exaggerated by using a coarser scale for it than for that of the piston The result is an oval curve, from which the events in the

[1] See a paper by Mr T Urquhart, *Min Proc Inst C E*, 1884, also *Engineering*, June 11-25, 1886

steam distribution are determined by drawing lines AB and CD parallel to the piston's path and distant from it by the amount of the outside and inside lap respectively Then a, b, c, and d, and the corresponding points p, q, r, and s determine the four events as in former diagrams Fig 65 shows at a glance the amount of steam opening at any part of the period of admission AE is the lead The events for the other side of the piston are determined by drawing AB above and CD below the middle line

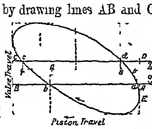

FIG 65 —Oval Diagram of Slide Valve Motion

147 The graphic construction most usually employed in slide-valve investigations is the ingenious diagram published by Dr G Zeuner in the *Civilingenieur* in 1856 [1] On the line AB (fig 66), which represents the travel of the valve, let a pair of circles (called valve circles) be drawn, each with diameter equal to the half travel A radius vector CP, drawn in the direction of the eccentric at any instant, is cut by one of the circles at Q, so that CQ represents the corresponding displacement of the valve from its middle position That this is so will be seen by drawing PM (as in fig 59) and joining QB, when it is obvious that CQ=CM, which is the displacement of the valve The line AB with the circles on it may now be turned back through an angle of $90°+\theta$ (θ being the angular advance), so that the valve circles take the position shown to a larger scale in fig 67 This makes the direction of CQ (the

Zeuner's diagram

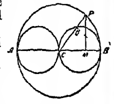

Fig 66

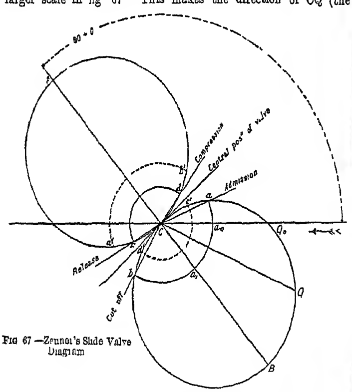

FIG 67 —Zeuner's Slide Valve Diagram

eccentric) coincide on the paper with the simultaneous direction of the crank, and hence to find the displacement of the valve at any position of the crank we have only to draw CQ in fig 67 parallel to the crank, when CQ represents the displacement of the valve to the scale on which the diameter of each valve circle represents the half-travel of the valve CQ_0 is the valve displacement at the beginning of the stroke shown by the arrow Draw circular arcs ab and cd with C as centre and with radii equal to the outside lap o and the inside lap i respectively Ca is the position of the crank at which preadmission occurs The lead is a_0Q_0 The greatest steam opening is a_1B The cut off occurs when the crank has the direction Cb Cc is the position of the crank at release, and Cd marks the end of the exhaust

148 In this diagram radii drawn from C mark the angular positions of the crank, and their intercepts by the valve circles determine the corresponding displacement of the valve It remains to find the corresponding displacement of the piston For this Zeuner employs a supplementary graphic construction, shown in fig 68 Here ab or $a'b'$ represents the connecting rod, and bc or $b'c$ the crank. With centre c and radius ac a circle ap is drawn, and with centre b and radius ab another circle aq Then for any

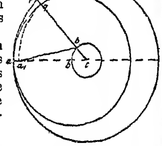

Fig 68

[1] Zeuner, *Treatise on Valve Gears*, transl by M Müller, 1868

position of the crank, as cb', the intercept pq between the circles is easily seen to be equal to aa', and is therefore the distance by which the piston has moved from its extreme position at the beginning of the stroke In practice this diagram is combined with that of fig 67, by drawing both about the same centre and using different scales for valve and piston travel A radius vector drawn from the centre parallel to the crank in any position then shows the valve's displacement from the valve's middle position by the intercept CQ of fig 67, and the piston's displacement from the beginning of the piston's motion by the intercept pq of fig 68

149 In all the figures which have been sketched the events refer to the front end of the cylinder, that is the end nearest to the crank (see fig 63) To determine the events of steam distribution at the back end, the lap circles shown by dotted lines in fig 67 must also be drawn, Ca' being the outside lap for the back end, and Cc' the inside lap These laps are not necessarily equal to those at the other end of the valve From fig 65 it is obvious that, especially with a short connecting rod, the cut off and release occur earlier and the compression later at the front than at the back end if the laps are equal, and a more symmetrical steam distribution can be produced by making the inside lap greater and the outside lap less on the side which leads to the front end of the cylinder On the other hand, an unsymmetrical distribution may be desirable, as in a vertical engine, where the weight of the piston assists the steam during the down-stroke and resists it during the up stroke, and this may be secured by a suitable inequality in the laps

150 By varying the ratio of the laps o and i to the travel of the valve, we produce effects on the steam distribution which are readily traced in the oval diagram of fig 65 or in the other figures Reduction of travel (which is equivalent to increase of both o and i) gives later preadmission, earlier cut-off, later release, and earlier compression, the ratios of expansion and of compression are both increased The effect of a change in the angular advance is more easily seen by reference to Zeuner's diagram, which shows that to increase θ accelerates all the events and causes a slight increase in the ratio of expansion

151 In designing a slide-valve the breadth of the steam ports in the direction of the valve's motion is determined with reference to the volume of the exhaust steam to be discharged in a given time, the area of the ports being generally such that the mean velocity of the steam during discharge is less than 100 feet per second The travel is made great enough to keep the cylinder port fully open during the greater part of the exhaust, for this purpose it is $2\frac{1}{2}$ or 3 times the breadth of the steam port To facilitate the exit of steam the inside lap is always small, and is often wanting or even *negative* During admission the steam port is rarely quite uncovered, especially if the outside lap is large and the travel moderate Large travel has the advantage of giving freer ingress and egress of steam, with more sharply defined cut off, compression, and release, but this advantage is secured at the cost of more work spent in moving the valve and more wear of the faces To lessen the necessary travel without reducing the area of steam ports, double- and even treble ported valves are often used An example of a double ported valve is shown in fig 85 Fig 69 shows the Trick valve, an ingenious device for the same purpose

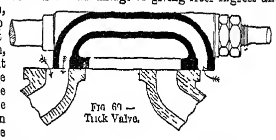

FIG 69 —Trick Valve.

152 The eccentric must stand in advance of the crank by the angle $90°+\theta$, as in fig 70, where CK is the crank, and CE the corresponding position of the eccentric when the engine is running in the direction of the arrow a To set the engine in gear to run in the opposite direction (b) it is only necessary to shift the eccentric into the position CE', when it will still be $90°+\theta$ in advance of the crank In the older engines this reversal was effected by temporarily disengaging the eccentric-rod from the valve-rod, working the valve by hand until the crank turned back through an angle equal to ECE', the eccentric meanwhile remaining at rest, and then re engaging the gear The eccentric sheave, instead of being keyed to the shaft, was driven by a stop fixed to the shaft, which abutted on one or other of two shoulders projecting from the sheave In some modern forms of reversing gear means are provided for turning the eccentric round on the shaft, but the arrangement known as the link motion is now the most usual gear in locomotive, marine, winding, and other engines which require to be often and easily reversed.

Reversal of motion with slide valve.

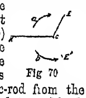

Fig 70

153. In the link motion two eccentrics are used, and the ends of their rods are connected by a link In Stephenson's link-motion— the earliest and still the most usual form—the link is a slotted bar or pair of bars curved to the same radius as the eccentric rods (fig 71), and capable of being shifted up or down by a suspension rod.

Link-motion. Stephenson's.

The valve rod ends in a block which slides within the link, and when the link is placed so that this block is nearly in line with the forward eccentric rod (R, fig 71) the valve moves in nearly the same way as if it were driven directly by a single eccentric. This is the position of "full forward gear." In "full backward gear," on the other hand, the

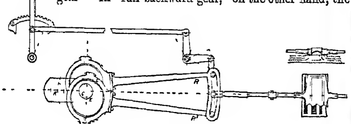

FIG 71.—Stephenson's Link Motion

link is pulled up until the block is in nearly a line with the backward eccentric rod R'. The link-motion thus gives a ready means of reversing the engine,—but it does more than this. By setting the link in an intermediate position the valve receives a motion nearly the same as that which would be given by an eccentric of shorter radius and of greater angular advance, and the effect is to give a distribution of steam in which the cut-off is earlier than in full gear, and the expansion and compression are greater. In mid gear the steam distribution is such that scarcely any work is done in the cylinder. The movement of the link is effected by a hand lever, or by a screw, or (in large engines) by an auxiliary steam engine. A usual arrangement of hand lever, sketched in fig 71, has given rise

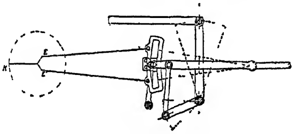

FIG 72.—Gooch's Link-Motion

to the phrase "notching up," to describe the setting of the link to give a greater degree of expansion.

Gooch's link-motion

154. In Gooch's link-motion (fig 72) the link is not moved up

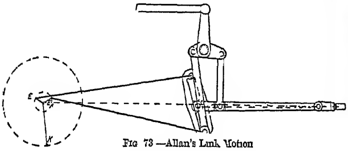

FIG 73.—Allan's Link Motion

in shifting from forward to backward gear, but a radius rod between the valve rod and the link (which is curved to suit this radius rod) is raised or lowered—a plan which has the advantage that the lead is the same in all gears.

Allan's

In Allan's motion (fig 73) the change of gear is effected partly by shifting the link and partly by shifting a radius rod, and the link is straight.

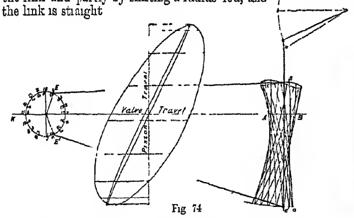

Fig 74

Graphic solution of link-motion

155. The movement of a valve driven by a link motion may be very fully and exactly analysed by drawing with the aid of a template the positions of the centre line of the link corresponding to a number of successive positions of the crank. Thus, in fig 74, two circular arcs passing through e and e' are drawn with E and E' as centres and the eccentric rods are radii. These are loci of two known points of the link, and a third locus is the circle a in which the point of suspension must lie. By placing on the paper a template of the link, with these three points marked on it, the position of the link is readily found, and by repeating the process for other positions of the eccentrics a diagram of positions (fig 74) is drawn for the assigned state of the gear. A line AB drawn across this diagram in the path of the valve's travel determines the displacements of the valve, and enables the oval diagram to be drawn (as in fig 65), which is shown to a larger scale in another part of fig 74. The example refers to Stephenson's link motion in nearly full forward gear; with obvious modification the same method may be used in the analysis of Gooch's or Allan's motion. The same diagram determines the amount of slotting or sliding motion of the block in the link. In a well designed gear this sliding is reduced to a minimum for that position of the gear in which the engine runs most usually. In marine engines the suspension rod is generally connected to the link at the end of the link next the forward eccentric, to reduce this sliding when the engine is in forward gear.

Equivalent eccentric

A less laborious, but less accurate, solution of link motion problems is reached by the use of what is called the equivalent eccentric—an imaginary eccentric, which would give the valve nearly the same motion as it gets from the joint action of the actual eccentrics. The following rule for finding the equivalent eccentric, in any state of gear, is due to Mr M'Farlane Gray:—

Connect the eccentric centres E and E' (fig 75) by a circular arc whose radius $= \dfrac{EE' \times \text{length of eccentric rod}}{2 \times cc'}$.

Fig 75

Then, if the block is at any point B, take EF such that EF : EE' :: eB : ee'. CF then represents the equivalent eccentric both in radius and in angular position. If the rods of the link motion are crossed instead of open,—an arrangement seldom used,—the arc EFE' is to be drawn convex towards C.

Other reversing gears.

156. Many forms of gear for reversing and for varying expansion have been devised with the object of escaping the use of two eccentrics, and of obtaining a more perfect distribution of steam than the link-motion can often be made to give.

Hackworth's.

Hackworth's gear, the parent of several others, has a single eccentric E (fig 76) opposite the crank, with an eccentric rod EQ, whose mean position is perpendicular to the travel of the valve. The rod ends in a block Q, which slides on a fixed inclined guide bar or link, and the valve-rod receives its motion through a connecting rod from an intermediate point P of the eccentric rod, the locus of which is an ellipse. To reverse the gear the guide-bar is tilted over to the position shown by the dotted lines, and intermediate inclinations give various degrees of expansion without altering the lead. The steam distribution is excellent, and the cut off is sharper than in

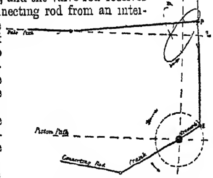

FIG 76.—Hackworth's Valve Gear

the usual link motion, but an objection to the gear is the wear of the sliding-block and guide.

Bremme's or Marshall's.

In Bremme's or Marshall's form this objection is obviated with some loss of symmetry in the valve's motion by constraining the motion of the point Q, not by a sliding guide, but a suspension-link, which makes the path of Q a circular arc instead of a straight line; to reverse the gear the centre of suspension R of this link is thrown over to the position R' (fig 77). In the example sketched P is beyond Q, but P may be between Q and the crank (as in fig 76), in which case the eccentric is set at 180° from the crank. This gear has been applied in a number of marine engines.

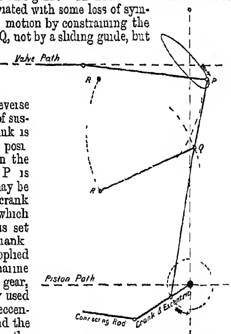

FIG 77.—Bremme's or Marshall's Valve Gear

Joy's.

In Joy's gear, which is extensively used in locomotives, no eccentric is required, and the rod corresponding to the eccentric rod in Hackworth's gear receives its motion from a point in the connecting rod by the linkage shown in fig 78, and is either suspended, as in Marshall's form, by a rod whose suspension centre R is thrown over to reverse the motion, or constrained, as in Hackworth's, by a slot-guide whose inclination is reversed. Fig 79 shows Joy's gear as

applied to a locomotive A slot guide E is used, and it is curved to allow for the obliquity of the valve connecting rod AE C is the crank-pin, B the piston path, and D a fixed centre The reversing gears of Walschaert, Brown, and Kitson also dispense with eccentrics, and are closely related to the invention of Hackworth [1] A

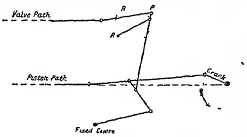

FIG 78 —Diagram of Joy's Valve Gear

method of reversing with a common slide valve, which is used in steam steering engines [2] and some others, is to supply steam to

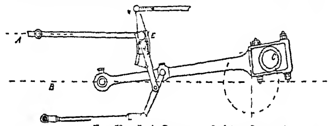

FIG 79 —Joy's Gear as applied to a Locomotive

what was (before reversal) the exhaust side of the valve and connect the exhaust to what was the steam side This is done by means of a separate reversing valve through which the steam and exhaust pipes pass

Separate expansion valves 157 When the distribution of steam is effected by the slide-valve alone the arc of the crank's motion during which compression occurs is equal to the arc during which expansion occurs, and for this reason the slide valve would give an excessive amount of compression if it were made to cut off the supply of steam earlier than about half-stroke Hence, where an early cut-off is wanted it is necessary either to use an entirely different means of regulating the distribution of steam, or to supplement the slide valve by another valve,—called an expansion-valve, usually driven by a separate eccentric,—whose function is to effect the cut off, the other events being determined as usual by the slide valve Such expansion valves belong generally to one or other of two types In one the expansion-valve cuts off the supply of steam to the chest in which the main valve works This may be done by a disk or double beat valve (§ 163), as in the Proell gear mentioned in § 175 below, or by a slide valve working on a fixed seat (furnished with one or more ports), which forms the back or side of the main valve chest Valves of this last type are usually made in the "gridiron" or many-ported form to combine large steam opening with small travel Expansion valves working in a fixed seat may be arranged so that the ports are either fully open (fig 80) or closed (fig 81) when the valve is in its middle position In the latter case the expansion valve eccentric is set in line with or opposite to the crank, if the engine is to run in either direction with the same grade of expansion

Fig 80

Fig 81

Cut-off then occurs at P, fig 82, when the shaft has turned through an angle ϕ from the beginning of the stroke The expansion valve reopens at Q, and the slide valve must therefore have enough lap to cut off earlier than $180° - \phi$ from the beginning of the stroke, in order to prevent a second admission of steam to the cylinder In the valve of fig 80 the expansion

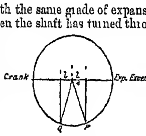

Fig 82

eccentric is set at right angles to the crank, if the action is to be the same in both directions If not, these angles may be deviated

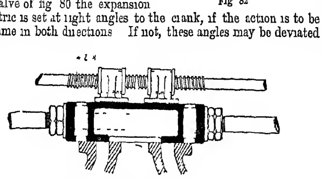

FIG 83 —Expansion Valve on back of Main Slide Valve

from, and in this way a more rapid travel at the instant of cut-off may be secured for one direction of running

158 The other and much commoner type of expansion valve is one sliding on the back of the main slide valve, which is provided with through ports which the expansion valve opens and closes Fig 83 shows one form of this type Here the resultant relative motion of the expansion valve and main valve has to be considered If r_a and r_b (fig 84) are the eccentrics working the main and expansion valves respectively, then CR drawn equal and parallel to ME is the *resultant* eccentric which determines the motion of the expansion valve relatively to the main valve Cut off occurs at

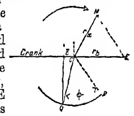

Fig 84

Q, when the shaft has turned through an angle ϕ, which brings the resultant eccentric into the direction CQ and makes the relative displacement of the two valves equal to the distance l Another form of this valve (corresponding to fig 81) cuts off steam at the inside edges of the expansion-slides

Variation of cut-off 159 Expansion-valves furnish a convenient means of *varying* the expansion, which may be done by altering their lap, travel, or angular advance Alteration of lap, or rather of the distance l in the figures, is often effected by having the expansion valve in two parts (as in fig 83) and holding them on one rod by right- and left-handed screws respectively, by turning the valve-rod the parts are made to approach or recede from each other In large valves the adjustment is more conveniently made by varying the travel of the valve, which is done by connecting it to its eccentric through a link which serves as a lever of variable length

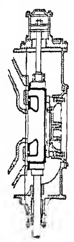

Fig 85

Relief rings. 160 To relieve the pressure of the valve on the seat, large slide-valves are generally fitted with a steam-tight ring, which excludes steam from the greater part of the back of the valve The ring fits steam tight into a recess in the cover of the steam-chest, and is pressed by springs against the back of the valve, which is planed smooth to slide under the ring Fig 85 shows a relief ring of this kind fitted on the back of a large double-ported slide-valve for a marine engine Another plan is to fit the ring into a recess on the back of the valve, and let it slide on the inside of the steam-chest cover Steam is thus excluded from the space within the ring, any steam that leaks in being allowed to escape to the condenser (or to the intermediate receiver when the arrangement is fitted to the high-pressure cylinder of a compound engine) A flexible diaphragm has also been used, instead of a recess, to hold the ring

Piston slide-valve. 161 The pressure of valves on cylinder faces is still more completely obviated by making the back of the valve similar to its face, and

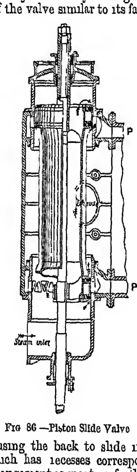

FIG 86 —Piston Slide Valve

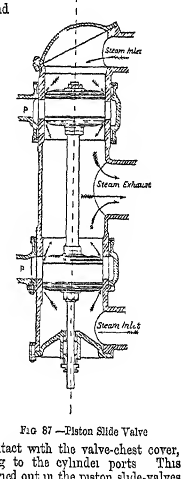

FIG 87 —Piston Slide Valve

causing the back to slide in contact with the valve-chest cover, which has recesses corresponding to the cylinder ports This arrangement is most perfectly carried out in the piston slide-valves now very largely used in the high pressure cylinders of marine engines The piston slide valve may be described as a slide-valve

[1] Reversing gears of this type are generally termed radial gears A discussion of Mr Joy's and other arrangements will be found in *Proc Inst Mech Eng*, 1880 Mr Kirk, Mr Bryce Douglas, and others have designed forms which more or less resemble those mentioned in the text

[2] *Proc Inst Mech Eng*, 1867

in which the valve face is curved to form a complete cylinder, round whose whole circumference the ports extend. The pistons are packed like ordinary cylinder pistons by metallic rings, and the ports are crossed here and there by diagonal bars to keep the rings from springing out as the valve moves over them. Figs. 86 and 87 show two forms of piston valve designed by Mr Kirk for the supply of high pressure steam to large marine engines. P, P are the cylinder ports in each.

Balance piston.

Fig. 85 illustrates an arrangement common in all heavy slide-valves whose travel is vertical—the *balance piston*, which is pressed up by steam on its lower side and so equilibrates the weight of the valve, valve rod, and connected parts of the mechanism.

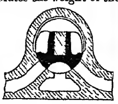

Fig. 88.—Rocking Slide Valve.

162. The slide valve sometimes takes the form of a disk revolving or oscillating on a fixed seat, and sometimes of a rocking cylinder (fig. 88). This last kind of sliding motion is very usual in stationary engines fitted with the Corliss gear, which will be described in the next chapter, in which case four distinct rocking slides are commonly employed to effect the steam distribution, one giving admission and one giving exhaust at each end of the cylinder (see fig. 127).

Double-beat valve.

163. In many stationary engines *lift* or *disk* valves are used, worked by tappets, cams, or eccentrics. Lift valves are generally of the Cornish or double beat type (fig. 89), in which equilibrium is secured by the use of two conical faces which open or close together. In Cornish pumping engines, which retain the single action of Watt's early engine, three double-beat valves are used, as steam-valve, equilibrium-valve, and exhaust valve respectively. These are closed by tappets on a rod moving with the beam, but are opened by means of a device called a cataract, which acts as follows.

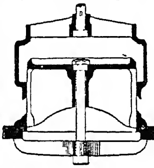

Fig. 89.—Double Beat Lift Valve.

Cornish cataract.

The cataract is a small pump with a weighted plunger, discharging fluid through a stop cock which can be adjusted by hand when it is desired to alter the speed of the engine. The weighted plunger is raised by a rod from the beam, but is free in its descent, so that it comes down at a rate depending on the extent to which the stop-cock is opened. When it comes down a certain way it opens the steam and exhaust valves, by liberating catches which hold them closed; the "out door" stroke then begins and admission continues until the steam-valve is closed: this is done directly by the motion of the beam, which also, at a later point in the stroke, closes the exhaust. Then the equilibrium valve is opened, and the "in door" stroke takes place, during which the plunger of the cataract is raised. When it is completed, the piston pauses until the cataract causes the steam valve to open and the next "out-door" stroke begins. By applying a cataract to the equilibrium-valve also, a pause is introduced at the end of the "out-door" stroke. Pauses have the advantage of giving the pump time to fill and of allowing the pump-valves to settle in their seats without shock.

IX. Governing.

Methods of regulating.

164. To make an engine run steadily an almost continuous process of adjustment must go on, by which the amount of work done by the steam in the cylinder is adapted to the amount of external work demanded of the engine. Even in cases where the demand for work is sensibly uniform, fluctuations in boiler pressure still make regulation necessary. Generally the process of government aims at regularity of speed; occasionally, however, it is some other condition of running that is maintained constant, as when an engine driving a dynamo electric machine is governed by an electric regulator to give a constant difference of potential between the brushes.

The ordinary methods of regulating are either (*a*) to alter the pressure at which steam is admitted by opening or closing more or less a throttle-valve between the boiler and the engine, or (*b*) to alter the volume of steam admitted to the cylinder by varying the point of cut off. The former plan was introduced by Watt and is still common, especially in small engines. From the point of view of heat economy it is wasteful, since the process of throttling is essentially irreversible, but this objection is to some extent lessened by the fact that the wire drawing of steam dries or superheats it, and consequently reduces the condensation which it suffers on coming into contact with the chilled cylinder walls. On the other hand, to hasten the cut off involves a gain rather than a loss of efficiency unless the ratio of expansion is already very great. The second plan of regulating is much to be preferred, especially when the engine is subject to large variations of load, and is very generally followed in stationary engines of the larger types.

165. Within certain limits regulation by either plan can be effected by hand, but for the finer adjustment of speed some form of automatic governor is necessary. Speed governors are commonly of the *centrifugal* type: a pair of masses revolving about a spindle which is driven by the engine are kept from flying out by a certain controlling force. When an increase of speed occurs this controlling force is no longer able to keep the masses revolving in their former path; they move out until the controlling force is sufficiently increased, and in moving out they act on the regulator of the engine, which may be a throttle valve or some form of automatic expansion gear. In the conical pendulum governor of Watt (fig. 90) the revolving masses are balls attached to a vertical spindle by links, and the controlling force is furnished by the weight of the balls, which, in receding from the spindle, are obliged to rise. When the speed exceeds or falls short of its normal value they move out or in, and so raise or lower a collar C which is in connexion by a lever with the throttle valve. The suspension-links may be hung from a cross bar (figs. 94, 95) instead of being pivoted in the axis of the spindle.

Centrifugal speed governors.

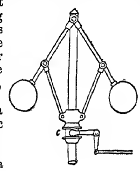

Fig. 90.—Watt's Governor.

Load governor.

166. In a modified form of Watt's governor, known as Porter's, or the loaded governor, a supplementary controlling force is given by placing a weight on the sliding collar (fig. 91). This is equivalent to increasing the *weight* of the balls without altering their *mass*. In other governors the controlling force is wholly or partly produced by springs. Fig. 92 shows a governor by Messrs Tangye in which the balls are controlled partly by their own weight and partly by a spring, the tension of which is regulated by turning the cap A.

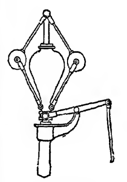

Fig. 91.—Loaded Governor.

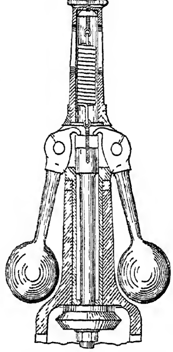

Fig. 92.—Spring Governor (Tangye).

Equilibrium of governor.

167. In whatever way the revolving masses are controlled, the controlling force may be treated as a force F acting on each ball in the direction of the radius towards the axis of revolution. Then, if M be the mass of the ball, n the number of revolutions per second, and r the radius of the ball's path, the governor will revolve in equilibrium when $F = 4\pi^2 n^2 r M$ (in absolute units), or

$$n = \frac{1}{2\pi}\sqrt{\frac{F}{Mr}}.$$

Condition of stability.

In order that the configuration of the governor should be stable, F must increase more rapidly than r, as the balls move outwards. In the simple conical pendulum governor, any of the three forms shown in figs. 93, 94, and 95, where the balls have no load to raise

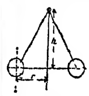

Fig. 93.

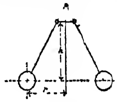

Fig. 94.

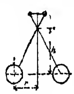

Fig. 95.

Fig. 96.

Gravity governor.

but their own weight, the controlling force F is the resultant of T, the tension in the link, and Mg, the weight of the ball (fig. 96). Let the height of the pendulum, that is, the distance above the plane of the balls of the point where the suspending-link, or the link produced, cuts the axis, be called h. Then $F : Mg :: r : h$. Hence

$$F = \frac{Mgr}{h}, \text{ and } n = \frac{1}{2\pi}\sqrt{\frac{g}{h}}.$$

Any change of n tends to produce a change of h, and, if the governor itself and the regulating mechanism attached to it were free

from friction, only one position of the governor would be possible for any one value of n. It is obvious that neither this governor nor any other *stable* governor maintains a strictly constant speed in the engine which it controls. If the boiler pressure or the demand for work is changed, a certain amount of permanent displacement of the balls is necessary to alter the steam supply, and the balls can retain their displaced position only by virtue of a permanent change in the speed. The maximum range of speed depends on that amount of change of n which suffices to alter the configuration of the governor from the position which gives no steam supply to the position which gives full steam supply, and the governor is said to be sensitive if this range is a small fraction of n.

Sensibility

Loaded gravity governor

168. If the governor is loaded, let M' be the amount of the load per ball, and q the velocity ratio of the vertical movement of the load to the vertical movement of the ball. Then $qM'g$ is the equivalent increase in the weight of each ball. The effect of the load is to increase the controlling force F from Mgr/h to $(M+qM')gr/h$, and the speed at which the governor must now turn, to maintain any assigned height h, is

$$n=\frac{1}{2\pi}\sqrt{\frac{(M+qM')g}{Mh}}$$

The speed of the loaded governor must therefore be greater than that of an unloaded governor of the same height in the ratio $\sqrt{(M+qM')}$ to $\sqrt{M}$.

The sensibility is then the same as that of an unloaded governor of the same height h, but the loaded governor has an important advantage in another respect—namely, its *power* or capability of overcoming frictional resistance to a change of configuration. This quality in a governor is increased whenever the controlling force F is increased, whether by the addition of a load or by the use of springs.

Power

For let f be the frictional resistance to be overcome per ball, resolved as a force resisting the displacement of each ball in the direction of the radius r. Then if n be the speed normal to any configuration this speed must change by a certain amount Δn before friction is overcome and the balls begin to be displaced. The controlling force is now $F+f$ when the balls are moving outwards, and $F-f$ when the balls are moving inwards. Hence

$$n+\Delta n=\frac{1}{2\pi}\sqrt{\frac{F+f}{Mr}},$$

and

$$n-\Delta n=\frac{1}{2\pi}\sqrt{\frac{F-f}{Mr}}.$$

From this, if Δn be small compared with n, we have $\Delta n/n=f/2F$.

Thus, when a given amount of frictional resistance is to be overcome before the governor can act, the limits within which this friction allows the speed to vary are less the greater is the controlling force F. A loaded governor is more powerful in this respect than an unloaded governor of the same configuration in the proportion in which F is greater—namely, as $M+qM'$ is to M. A loaded governor may therefore have much lighter revolving masses without loss either of sensibility or of power.

General solution graphic method

169. The same results are applicable to governors in which the controlling force is supplied by springs as well as by gravity, or by springs alone. To find the configuration which the governor will assume at any particular speed, or the speed corresponding to a particular configuration, it is only necessary to determine the whole controlling force F per ball acting along the radius towards the axis for various values of r. Let a curve ab (fig. 97) be drawn showing the relation of F to r. At any assigned value of r set up an ordinate $QC=4\pi^2n^2rM$. Join OC. The point c, in which OC cuts the curve, determines the value of r at which the balls will revolve at the assigned speed n. Or, if that is given, and the value of n is to be found, the line Oc produced will determine C, and then $n^2=QC/4\pi^2rM$. The sensibility of the governor is determined by taking points a and b corresponding to full steam and no steam respectively, and drawing lines through them to determine the corresponding values of QA and QB.[1] When the frictional resistance f is known, an additional pair of curves drawn above and below ab, with ordinates $F+f$ and $F-f$ respectively, serve to show the additional variations in speed which are caused by friction. The governor is stable throughout its whole range when the curve ab has a steeper gradient than any line drawn from O to meet it.

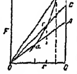

Fig. 97.

Isochronism

170. By § 167 it is evident that, if, when the balls are displaced, the controlling force F changes proportionally to the radius r, the speed is constant. In other words, the equilibrium of the governor is then neutral, it can revolve in equilibrium at one, and only at one, speed. At this speed it assumes, indifferently, any one of its possible configurations. The slightest variation of speed drives it to the extremity of its range, hence its sensibility is indefinitely great. Such a governor is called *isochronous*. A gravity governor is isochronous when h is constant for all positions of the balls (since $n \propto \sqrt{g/h}$). This will be the case if the balls are constrained to move in a parabolic path (fig. 98), it being a property of the parabola that the subnormal QM, which is h, is constant. A useful approximation to the same condition, through a limited range, is secured in Farcot's governor by the device of hanging the balls by crossed links from the distant ends of a T piece (fig. 95). If each centre of suspension were at the centre of curvature of a parabolic arc which coincided with the actual circular locus of the balls at the position of normal speed, the governor would be sensibly isochronous at that speed; by taking the centres of suspension rather nearer the axis, a suitable margin of stability is secured, but the governor is still nearly enough isochronous to be exceedingly sensitive.[2] Where springs furnish the controlling force, an approach to isochronism can be secured by adjusting the initial tension of the springs, and this forms a convenient means of regulating the sensibility. Thus, in Mr Hartnell's apparatus (fig. 99), where the balls move in a nearly horizontal direction, and gravity has little to do with the control, the governor can be made isochronous by screwing down the spring, so that the initial force exerted by the spring is to its increase by displacement of the balls as the initial radius of the balls' path is to the increase of radius by displacement. When the initial force is increased beyond this the governor becomes unstable. In fig. 97 the condition of isochronism is secured when the line ab coincides with a straight line through O.

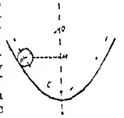

Fig. 98.

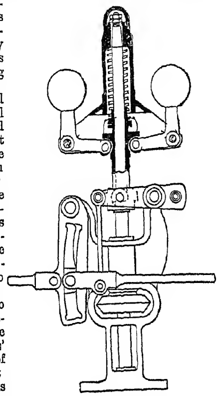

Fig. 99.—Hartnell's Governor.

171. In practice no governor can be absolutely isochronous. It is indispensable to leave a small margin of stability for the sake of preventing violent change in the supply of steam, especially when there is much frictional resistance to be overcome by the governor, or where the influence of the governor takes much time to be felt by the engine. An over sensitive governor is liable to fall into a state of oscillation called *hunting*. When an alteration of speed begins to be felt, however readily the governor alters its form, the engine's response is more or less delayed. If the governor acts by closing a throttle valve, the engine has still a capacious valve chest on which to draw for steam. If it acts by changing the cut off, its opportunity is passed if the cut off has already occurred, and the control only begins with the next stroke. This lagging of effect is specially felt in compound engines, where that portion of the steam which is already in the engine continues to do its work for nearly a whole revolution after passing beyond the governor's control. The result of this storage of energy in an engine whose governor is too nearly isochronous is that, whenever the demand for power suddenly falls, the speed rises so much as to force the governor into a position of over control, such that the supply of steam is no longer adequate to meet even the reduced demand for power. Then the speed slackens, and the same kind of excessive regulation is repeated in the opposite direction. A state of forced oscillation is consequently set up. The effect is aggravated by the momentum which the governor balls acquire in being displaced, and also, to a very great degree, by the friction of the governor and the regulating mechanism. Hunting is to be avoided by giving the governor a fair degree of stability, by reducing as far as possible the static frictional resistances, and by introducing a *viscous* resistance to the displacement of the governor, which prevents the displacement from occurring too suddenly, without affecting the ultimate position of equilibrium. For this purpose many governors are furnished with a *dash pot*, which is an hydraulic or pneumatic brake, consisting of a piston connected to the governor, working loosely in a cylinder which is filled with oil or with air.

Hunting

Dash-pot.

172. In some high-speed engines the governor balls or blocks re-

volve in a vertical plane, about a horizontal axis, and the control is given wholly by springs An example is shown in fig 100, which is the governor of the Armington and Sims engine referred to in § 197 below Another example is furnished by the governor of Brotherhood's engine (§ 203, fig 128)

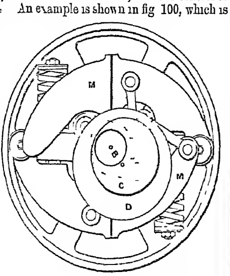

FIG 100 —Governor of Armington & Sims Engine

Throttle-valve

173 The throttle-valve, as introduced by Watt, was originally a disk turning on a transverse axis across the centre of the steam-pipe It is now usually a double-beat valve (fig 89) or a piston-valve When regulation is effected by varying the cut off, and an expansion valve of the slide valve type is used, the governor generally acts by changing the travel of the valve Fig 99 illustrates a common mode of doing this, by giving the expansion valve its motion from an eccentric rod through a link, the throw of which is varied by the displacement of the governor balls In fig 100, the governor acts on the main slide valve of the engine (there being no separate expansion valve), and the displacement of the revolving masses M, M changes both the throw and the angular advance of the eccentric, thereby producing a change in the steam supply similar to that produced by "notching up" a link motion The eccentricity B is altered by the relative displacement of two parts C, D into which the eccentric sheave is divided In other forms of automatic expansion gear the lap of the valve is altered, in others the governor acts by shifting the expansion valve eccentric round on its shaft, and so changing its angular advance

Automatic variation of cut off

Corliss gear.

174 In large stationary engines the most usual plan of automatically regulating the expansion is to employ some form of trip gear, the earliest type of which was introduced in 1849 by G H Corliss of Providence, U S In the Corliss system the valves which admit steam are distinct from the exhaust valves The latter are opened and closed by a reciprocating piece which takes its motion from an eccentric The former are opened by a reciprocating piece, but are closed by springing back when released by a trip- or trigger action The trip occurs earlier or later in the piston's stroke according to the position of the governor The admission-valve is opened by the reciprocating piece with equal rapidity whether the cut off is going to be early or late It remains wide open during the admis-

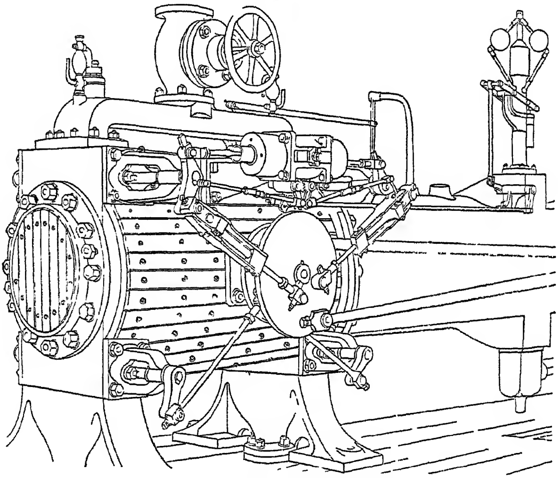

FIG 101 —Corliss Engine, with Spencer Inglis Trip Gear

sion, and then, when the trip action comes into play, it closes suddenly The indicator diagram of a Corliss engine consequently has a nearly horizontal admission-line and a sharply defined cut off Generally the valves of Corliss engines are cylindrical plates turning in hollow cylindrical seats which extend across the width of the cylinder Often, however, the admission-valves are of the disk or double beat type, and spring into their seats when the trip gear acts Many forms of Corliss gear have been invented by Corliss himself and by others One of these, the Spencer Inglis[1] trip gear, by Messrs Hick, Hargreaves, & Co, is shown in figs 101 and 102 A wrist-plate A, which turns on a pin on the outside of the cylinder, receives a motion of oscillation from an eccentric It opens the cylindrical rocking-valve B by pulling the link C, which consists of two parts, connected to each other by a pair of spring clips *a*, *a* Between the clips there is a rocking-cam *b*, and as the link is pulled down this cam places itself more and more athwart the link, until at a certain point it forces the clips open Then the upper part of the link springs back and allows the valve B to close by the action of a spring in the dash-pot D When the wrist-plate makes its return stroke the clips re engage the upper portion of the link C, and things are ready for the next stroke The rocking cam *b* has its position controlled by the governor through the link E in such a way that when the speed of the engine increases it stands more athwart the link C, and therefore

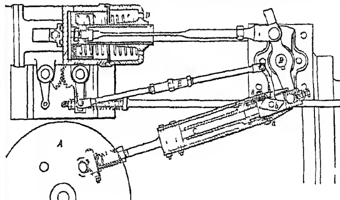

FIG 102 —Corliss Valve Gear, Spencer Inglis form

causes the clips to be released at an earlier point in the stroke A precisely similar arrangement governs the admission of steam to the other end of the cylinder The exhaust-valves are situated on the

[1] *Proc Inst Mech Eng*, 1868

bottom of the cylinder, at the ends, and take their motion from a separate wrist-plate which oscillates on the same pin with the plate A [1]

Proell's trip gear

175 Fig 103 shows a compact form of trip-gear by Dr Proell A rocking lever *ab* is made to oscillate on a fixed pin through its centre by a connexion to the crosshead of the engine When the end *a* rises, the bell-crank lever *c* engages the lever *d*, and when *a* is depressed the lever *d* is forced down and the valve *e* is opened to admit steam to one end of the cylinder As *a* continues moving down a point is reached at which the edge of *c* slips past the edge of *d*, and the valve is then forced to its seat by a spring in the dash pot *f* This disengagement occurs early or late according to the position of the fulcrum piece *g*, on which the heel of the bell-crank rests during the opening of the valve The position of *g* is determined by the governor A similar action, occurring at the other end of the rocking bar *ab*, gives steam to the other end of the cylinder In one form of Proell's gear both ends of *ab* act on the same steam valve, which is then a separate expansion-valve fixed on the back of a chest in which an ordinary slide valve works

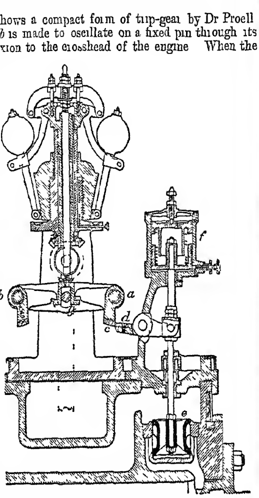

FIG 103 —Proell's Automatic Expansion Gear

Disengagement governors

176 In the ordinary form of centrifugal governor the position of the throttle valve, or the expansion link, or the Corliss trigger depends on the configuration of the governor, and is definite for each position of the balls In disengagement governors, of which the governor A shown on the right hand side in fig 104 is an example, any reduction of speed below a certain value sets the regulating mechanism in motion, and the adjustment continues until the speed has been restored Similarly a rise of speed above a certain value sets the regulating mechanism in motion in the other direction If the spindle *a* (fig 104) is connected to the regulator so as to give more steam if it turns one way and less if it turns the other, the speed at which the engine will run in equilibrium must lie between narrow limits, since at any speed high enough to keep *b* in gear with *a* the supply of steam will go on being reduced, and at any speed low enough to bring *c* into gear with *a* the supply will go on being increased This mode of governing, besides being sensibly isochronous, has the advantage that the power of the governor is not limited by the controlling force on the balls, since the governor acts by deflecting a portion of the power that is being developed by the engine to the work of moving the regulator It is rarely applied to steam engines, probably because its action is too slow This defect has been ingeniously remedied in the supplementary governor of Mr W Knowles, who has combined a disengagement governor with one of the ordinary type in the manner shown in fig 104.[2] Here the spindle *a*, driven by the supplementary or disengagement governor A, acts by lengthening the rod *d* which connects the ordinary governor B with the regulator It does this by turning a coupling nut *e* which unites two parts of *d*, on which right- and left-handed screws are cut Any sudden fluctuation in speed is immediately responded to by the ordinary governor Any more or less permanent change of load or of steam-pressure gives the supplementary governor time to act It goes on adjusting the supply until the normal speed is restored, thereby converting the control of the ordinary governor, which is stable, and therefore not isochronous, into a control which is isochronous as regards all fluctuations of long period The power of the combination is limited to that of the common governor B

Knowles's supplementary governor

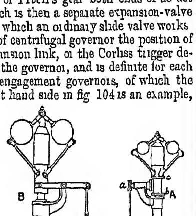

FIG 104 —Knowles's Supplementary Governor

Relay governors

177 Other governors which deserve to be classed as disengagement governors are those in which the displacement of the governor affects the regulator, not directly by a mechanical connexion, but by admitting steam or other fluid into what may be called a relay cylinder, whose piston acts on the regulator In order that a governor of this class should work without hunting, the piston and valve of the relay cylinder should be connected by what is termed differential gear, the effect of which is that for each displacement of the valve by the governor the piston moves through a distance proportional to the displacement of the valve An example of differential gear is shown in fig 105 Suppose that the rod *a* is connected with the governor so that it is raised by an acceleration of the engine's speed The rod *c* which leads from the relay piston *b* to the regulator serves as a fulcrum, and the valve rod *d* is consequently raised This admits steam to the upper side of the piston and depresses the piston, which pulls down *d* with it, since the end of *a* now serves as a fulcrum Thus by the downward movement of the piston the valve is again restored to its middle position and the action of the regulator then ceases until a new change of speed occurs A somewhat similar differential contrivance is used in steam-steering engines to make the position of the rudder follow, step by step, every movement of the hand-wheel,[3] also, in the steam reversing gear which is applied to large marine engines, to make the position of the drag link follow that of the hand lever, and also in certain electrical governors [4] The effect of adding a differential gear such as this to a relay governor or other disengagement governor is to convert it from the isochronous to the stable type

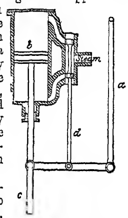

FIG 105 —Differential Gear for Relay Governor

Differential or dynamometric governors

178 Another group of governors is best exemplified by the "differential" governor of the late Sir W Siemens[5] (fig 106). A spindle *a* driven by the engine drives a piece *b* (whose rotation is resisted by a friction brake) through the dynamometer coupling *c*, consisting of a nest of bevel-wheels and a loaded lever *d* So long as the speed remains constant the rate at which work is done on the brake is constant and the lever *d* is steady If the speed accelerates, more power has to be communicated to *b*, partly to overcome the inertia and partly to meet the increased resistance of the brake, and the lever *d* is displaced The lever *d* works the throttle valve or other regulator, either directly or by a steam relay The governor is isochronous when the force employed to hold *d* in position does not vary, if the force increases when *d* is displaced, the governor is stable A governor of this class may properly be called a dynamometric governor, since it regulates by endeavouring to keep constant the rate at which energy is transmitted to the piece *b* In one form of Siemens's governor the friction brake is replaced by a sort of centrifugal pump, consisting of a paraboloidal cup, open at the top and bottom, whose rotation causes a fluid to rise in it and escape over the rim when the speed is sufficiently great Any increase in the cup's speed augments largely the power required to turn it, and consequently affects the position of the piece which corresponds to *d* [6] Siemens's governor is not itself used to any important extent, but the principle it embodies finds application in a number of other forms

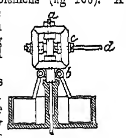

FIG 106 —Siemens's Governor

179 The "velometer" or marine engine regulator of Messrs Durham and Churchill[7] is a governor of the same type In it the rotation of a piece corresponding to *b* is resisted by means of a fan revolving in a case containing a fluid, and the coupling piece which is the mechanical equivalent of *d* in fig 106 acts on the throttle-valve, not directly but through a steam relay In Silver's marine governor [8] the only friction brake that is provided to resist the rotation of the piece which corresponds to *b* is a set of air vanes The inertia is, however, very great, and any acceleration of the engine's speed consequently displaces the dynamometer coupling,

[1] Numerous forms of Corliss gears are illustrated in W H Uhland's work on Corliss engines, translated by A Tolhausen (London, 1879) A more recent form of gear by Mr Inglis is described in *Engineering*, vol xl p 251

and so acts on the regulator in its effort to increase the speed of b

Another example of the differential type is the Allen[1] governor, which has a fan directly geared to the engine, revolving in a case containing a fluid The case is also free to turn, except that it is held back by a weight or spring and is connected to the regulator So long as the speed of the fan is constant, the moment required to keep the case from turning does not vary, and consequently the position of the regulator remains unchanged When the fan turns faster the moment increases, and the case has to follow it (acting on the regulator) until the spring which holds the case from turning is sufficiently extended, or the weight raised The term "dynamometric governor" is equally applicable to this form, the power required to drive the fan is regulated by an absorption dynamometer in the case instead of by a transmission-dynamometer between the engine and the fan In Napier's governor the case is fixed, and the reaction takes place between one turbine fan which revolves with the engine and another close to it which is held from turning by a spring and is connected with the regulator

Pump governors 180 Pump governors form another group closely related to the differential or dynamometric type An engine may have its speed regulated by working a small pump which supplies a chamber from which water is allowed to escape by an orifice of constant size When the engine quickens its speed water is pumped in faster than it can escape, and the accumulation of water in the chamber may be made to act on the regulator through a piston controlled by a spring or in other ways This device has an obvious analogy to the cataract of the Cornish pumping engine (§ 163), which has, however, the somewhat different purpose of introducing a regulated pause at the end of each stroke The "differential valve-gear" invented by Mr H Davey, and successfully applied by him to modern pumping-engines, combines the functions of the Cornish cataract with that of a hydraulic governor for regulating the expansion[2] In this gear, which is shown diagramatically in fig 107, the valve-rod of the engine (a) receives its motion from a lever b, one end of which (c) copies, on a reduced scale, the motion of the engine piston, while the other (d), which forms (so to speak) the fulcrum, has its position regulated by attachment to a subsidiary piston-rod, which is driven by steam in a cylinder e, and is forced to travel uniformly by a cataract f The point of cut-off is determined by the rate at which the main piston overtakes the cataract piston, and consequently comes early with light loads and late with heavy loads

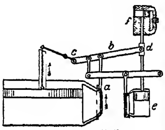

FIG 107 —Davey's Differential Valve Gear

Government of marine engines 181 The government of marine engines is peculiarly difficult on account of the sudden and violent fluctuations of load to which they are subjected by the alternate uncovering and submersion of the screw in a heavy sea However rapidly the governor responds to increase of speed by closing the throttle-valve, an excess of work is still done by the steam in the valve chest and in the high-pressure cylinder To check the racing which results from this, it has been proposed to supplement the control which the throttle valve on the steam-pipe exercises by throttling the exhaust or by spoiling the vacuum Probably a better plan is that of Messrs Jenkins and Lee, who give supplementary regulation by causing the governor to open a shunt-valve which connects the top and bottom of the low-pressure cylinder, thus allowing a portion of the steam in it to pass the piston without doing work In Dunlop's pneumatic governor[3] an attempt is made to anticipate the racing of the screw by causing the regulator to be acted on by the changes of pressure on a diaphragm which is connected by an air-pipe with an open vessel fixed under the stern of the ship A plan has recently been introduced by Mr W B Thompson to prevent the racing of marine engines by working the valves from a lay shaft which is driven at a uniform speed by an entirely independent engine So long as this lay shaft is not driven too fast the main engine is obliged to follow it, if the lay shaft is driven faster than the main engine can follow the main engine pauses so as to miss a stroke, and then goes on Reversing the motion of the lay shaft reverses the main engine

Moscrop recorder 182 In connexion with governors mention may be made of an apparatus introduced by Mr Moscrop to give a continuous record of fluctuations in the speed of engines[4] It resembles a small centrifugal governor, but the displacement of the balls actuates, not a regulator, but a pencil which moves transversely on a ribbon of paper that is moved continuously by clockwork The recorder responds so rapidly to changes of speed as to show not only the comparatively slow changes which occur from stroke to stroke, but also those short period fluctuations between a maximum and minimum, within the limits of each single stroke, which will be discussed in the next chapter

X The Work on the Crank-Shaft

183 Besides those variations of speed which occur from stroke to stroke, which it is the business of the governor to check, there are variations within each single stroke over which the governor has of course no control These are due to the varying rate at which work is done on the crank shaft during its revolution To limit them is the function of the fly wheel, which acts by forming a reservoir of energy to be drawn upon during those parts of the revolution in which the work done on the shaft is less than the work done by the shaft, and to take up the surplus in those parts of the revolution in which the work done on the shaft is greater than the work done by it This alternate storing and restoring of energy is accomplished by slight fluctuations of speed, whose range depends on the ratio which the alternate excess and defect of energy bears to the whole stock the fly wheel holds in virtue of its motion The effect of the fly wheel may be studied by drawing a diagram of crank-effort, which shows the work done on the crank in the same way that the indicator diagram shows the work done on the piston The same diagram serves another useful purpose in determining the twisting and bending stress in the crank Use of fly-wheel

184 The diagram of crank effort is best drawn by representing, in rectangular co ordinates, the relation between the moment which the connecting-rod exerts to turn the crank and the angle turned through by the crank When the angle is expressed in circular measure, the area of the diagram is the work done on the crank Diagram of crank-effort

Neglecting friction, and supposing in the first place that the engine runs so slowly that the forces required for the acceleration of the moving masses are negligibly small, the moment of crank-effort is found by resolving the thrust P of the piston rod into a

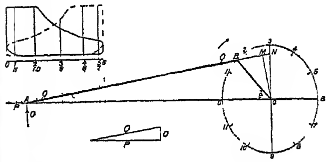

Fig 108

component Q along the connecting-rod and a component O normal to the surface of the guide (fig 108) The moment of crank-effort is

$$Q\ CM = P\ CN = Pr\sin\alpha\left(1+\frac{r\cos\alpha}{\sqrt{l^2-r^2\sin^2\alpha}}\right),$$

where CN is drawn perpendicular to the centre line or travel of the piston, r is the crank, l the connecting rod, and α the angle ACB which the crank makes with the centre line A graphic determination of CN is the most convenient in practice, unless the connecting rod is so long that its obliquity is negligible, when the second term in the above expression vanishes Fig 109 shows the diagram of crank effort determined in this way for an engine whose connecting-rod is $3\frac{1}{2}$ times the length of its crank, and in which steam is cut off at half stroke The thrust P is determined from the indicator diagrams of fig 108 by taking the excess of the forward pressure on one side of the piston over the back pressure on the other side, and multiplying this effective pressure by the area of the piston The area of the diagram of crank-effort is the work done per revolution

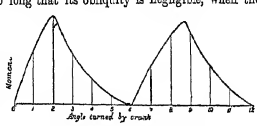

FIG 109 —Diagram of Crank-Effort

185 The friction of the piston in the cylinder and the piston-rod in the stuffing box is easily allowed for, when it is known, by making a suitable deduction from P Friction at the guides, at the crosshead, and at the crank-pin has the effect of making the stress at each of these places be inclined to the rubbing surfaces at an angle ϕ, the angle of repose, whose tangent is the coefficient of friction Hence O, instead of being normal to the guide, is inclined at the angle ϕ in the direction which resists the piston's motion (fig 110), and the thrust along the connecting-rod, instead of passing through the centre of each pin, is displaced far enough to make an angle ϕ with the radius at the point where it meets the pin's surface To satisfy this condition let a "friction-circle" be drawn about the centre of each pin, with radius equal to $a\sin\phi$, Effect of friction

[1] *Proc Inst Mech Eng*, 1873
[2] *Proc Inst Mech Eng*, 1874
[3] *Ibid*, 1879
[4] *Ibid*, 1884

where a is the actual radius of the pin. Any line drawn tangent to this circle will make the angle ϕ with the radius of the pin at the surface of the pin. The thrust of the connecting-rod must be tangent to both circles; it is drawn as in fig. 110, so that it resists the rotation of the pins relatively to the rod. The direction of rotation of the pins is shown by curved arrows in the figure, where the friction-circles are drawn to a greatly exaggerated scale. Finally, P (after allowing for the friction of piston packing and stuffing box) is resolved into O and Q, and Q. CM, the moment of Q on the shaft, is determined. This gives a diagram of crank-effort, correct so far as friction affects it, whose area is no longer equal to that of the indicator diagram. The difference, however, does not represent the whole work lost through friction of the mechanism, since the friction of the shaft itself, and of those parts of the engine which it drives, has still to be allowed for if the frictional efficiency of the engine as a whole is in question.

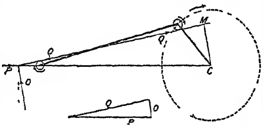

Fig. 110

Effect of inertia

186. The diagram of crank-effort is further modified when we take account of the inertia of the piston and connecting-rod. For the purpose of investigating the effects of inertia, we may assume that the crank is revolving at a sensibly uniform rate of n turns per second. Let M be the mass of the piston, piston rod, and crosshead in pounds, and a its acceleration at any instant in feet per second per second. The force required to accelerate it is Ma/g, in pounds weight, and this is to be deducted in estimating the effective value of P. The effect is to reduce P during the first part of the stroke and to increase it towards the end, thereby compensating to some extent for the variation which P undergoes in consequence of an early cut off. If the connecting-rod is so long that its obliquity may be neglected the piston has simple harmonic motion, and

$$a = -4\pi^2 n^2 r \cos\alpha = -4\pi^2 n^2 x,$$

where x is the distance of the piston from its middle position. More generally, whatever ratio the length l of the connecting-rod bears to that of the crank r,

$$a = -4\pi^2 n^2 r\left(\cos\alpha + \frac{rl^2\cos 2\alpha + r^3\sin^4\alpha}{(l^2 - r^2\sin^2\alpha)^{\frac{3}{2}}}\right)$$

The effect is to make, on the diagram of P, a correction of the character shown in fig. 111, where the broken line cd refers to the case of an indefinitely long connecting-rod and the full line ab to the case of a connecting-rod $3\frac{1}{2}$ times the length of the crank. In a vertical engine the weight of the piston and piston rod is to be added to or subtracted from P.

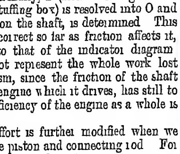

Fig. 111

To allow for the inertia of the connecting-rod is a matter of somewhat greater difficulty. Its motion may conveniently be analysed as consisting of translation with the velocity of the crosshead, combined with rotation about the crosshead as centre. Hence the force required for its acceleration is the resultant of three components—F_1, the force required for the linear acceleration a (which is the same as that of the piston), F_2, the force required to cause angular acceleration about the crosshead, and F_3, the force towards the centre of rotation, which depends on the angular velocity, and is equal and opposite to the so called centrifugal force. Let θ be the angle BAC (fig. 112), $\dot\theta$ the angular velocity of the rod about A, and $\ddot\theta$ its angular acceleration, and let M' be the mass of the rod. Then

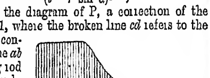

Fig. 112

$$F_1 = M'a/g,$$

and acts through the centre of gravity G, parallel to AC,

$$F_2 = M'\ AG\ \ddot\theta/g,$$

and acts at right angles to the rod through the centre of percussion H,

$$F_3 = M'\ AG.\ \dot\theta^2/g,$$

and acts along the rod towards A. Also,

$$\dot\theta = \frac{2\pi n r\cos\alpha}{\sqrt{l^2 - r^2\sin^2\alpha}},$$

and

$$\ddot\theta = \frac{-4\pi^2 n^2 r\sin\alpha(l^2 - r^2)}{(l^2 - r^2\sin^2\alpha)^{\frac{3}{2}}}$$

The moments of these forces about C are next to be found, and to be deducted from the moment of the thrust in the connecting-rod (and, if the weight of the rod is to be considered, its moment about C is to be added) in finding the resultant moment of crank effort.

187. If, however, the friction at the crosshead and crank-pin is to be taken account of, the whole group of forces acting on the rod must be considered as follows. Compound forces equal and opposite to F_1, F_2, and F_3 into a single force R (fig. 113), which may be called the resultant resistance to acceleration of the connecting-rod. If the weight of the rod is to be considered, let it also be taken as a component in reckoning R. Then the rod may in any position be regarded as in equilibrium under the action of the forces Q, R, and S, where Q and S are the forces exerted on it by the crosshead and crank pin respectively. These three forces meet in a point p in R, which is to be found by trial, the condition being that in the diagram of forces, fig. 114, after the triangle POQ has been drawn, and the force R set out, the force line S shall be parallel to a line drawn from p tangent to the friction-circle of the crank pin, as in fig. 113. When this condition has been satisfied by trial, the value of S, which is the thrust on the crank-pin, is determined, and S. CM is the moment of crank effort. This method is due to the late Prof. Fleeming Jenkin, who has applied it with great generality to the determination of the frictional efficiency of machinery in two important papers,[1] the second of which deals in detail with the dynamics of the steam engine. Fig. 114

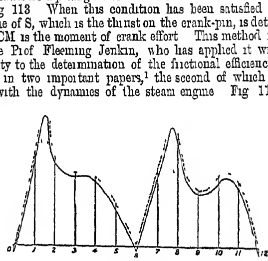

Fig. 115

from that paper, shows the diagram of crank-effort in a horizontal direct acting engine,—the full line with friction, and the dotted line without friction,—the inertia of the piston and connecting rod being taken account of, as well as the weight of the latter. It exhibits well the influence which the inertia of the reciprocating parts has in equalizing the crank effort in the case of an early cut-off. The cut off is supposed to occur pretty sharply at about one-sixth of the stroke. The engine considered is of practical proportions, and makes four turns per second, and the initial steam pressure is 50 lb per square inch. It appears from the diagram that, with a slightly higher speed, or with heavier rods, a better balance of crank-effort might be secured, especially as regards the stroke towards the crank, which comes first in the diagram; on the other hand, by unduly increasing the mass of the reciprocating pieces or their speed the inequality due to expansion would be over-corrected and a new inequality would come in.

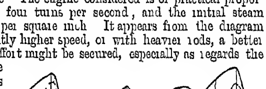

Fig. 116.—Crank-Effort Diagram for Two Cranks.

Combined diagrams

188. When two or more cranks act on the same shaft, the joint moment of crank-effort is found by combining the diagrams for the separate cranks, in the manner illustrated by fig. 116, which refers to the case of two cranks at right angles.

Circular diagram.

Another graphic method of exhibiting the variations of moment exerted on the crank shaft during a revolution is to draw a circular diagram of crank effort, in which lines proportional to the moment are set off radially from a circular line which represents the zero of moment. An example of this plan is given in fig. 117, which shows the resultant moment determined by Mr A. C. Kirk for one of his triple-expansion engines with three cranks set at 120° from each other. Curves are drawn for various speeds, giving in each case the resultant moment due to the steam pressure (as

[1] *Trans. Roy. Soc. Edin.*, vol. xxviii. p. 1 and p. 703.

determined from actual indicator diagrams) combined with the moments due to the inertia of the reciprocating parts The line marked 0 is the steam line without inertia—or, in other words,

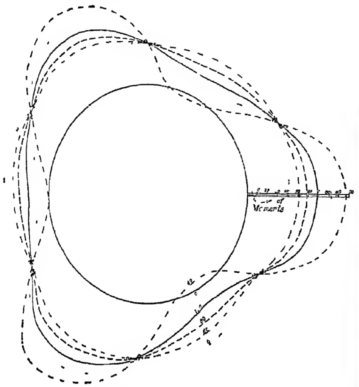

FIG 117 —Circular Diagram of Crank Effort for a Three Cylinder Engine

the curve corresponding to an indefinitely slow speed The other curves refer to the number of revolutions per minute marked on them

Fluctuations of speed

189 To determine the fluctuations of speed during a revolution, the resultant diagram of work done *on* the crank shaft is to be compared with a similar diagram drawn to show the work done *by* the shaft in overcoming its own friction, and in overcoming the resistance of the mechanism which it drives In general the resistance may be taken as constant, and the diagram of effort exerted by the crank-shaft is then a straight line, as EFGHIJKL in fig 118 At F, G, H, I, J, and K the rate at which work is being done on and by the shaft is the same, hence at these points the fly wheel is neither gaining nor losing speed The shaded area above FG is an excess of work

Function of fly-wheel

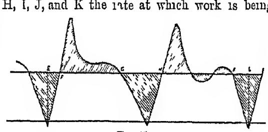

Fig 118

done on the crank, and raises the speed of the fly wheel from a minimum at F to a maximum at G From G to H the fly-wheel supplies the defect of energy shown by the shaded area below GH, by which the demand for work exceeds the supply, its speed again reaches a minimum at H, and again a maximum at I The excesses and defects balance in each revolution if the engine is making a constant number of turns per second In what follows it is assumed that they are only a small fraction of the whole energy held by the fly wheel

Let ΔE be the greatest single amount of energy which the fly-wheel has to give out or absorb, as determined by measuring the shaded areas of the diagram, and let ω_1 and ω_2 be the maximum and minimum values of the wheel's angular velocity, which occur at the extremes of the period during which it is storing or supplying the energy ΔE The mean angular velocity of the wheel ω_0 will be sensibly equal to $\frac{1}{2}(\omega_1+\omega_2)$ if the range through which the speed varies is moderate Let E_0 be the energy of the fly-wheel at this mean speed. Then

$$E_0=\tfrac{1}{2}I\omega_0^2,$$

where I is the moment of inertia of the fly-wheel

$$\Delta E=\frac{I(\omega_1^2-\omega_2^2)}{2}=I\omega_0(\omega_1-\omega_2)=2E_0\ \frac{(\omega_1-\omega_2)}{\omega_0}$$

The quantity $\frac{\omega_1-\omega_2}{\omega_0}$, which we may write q, is the ratio of the extreme range of speed to the mean speed, and measures the degree of unsteadiness which the fly-wheel leaves uncorrected If the problem be to design a fly-wheel which will keep q down to an assigned limit, the energy of the wheel must be such that

$$E_0=\frac{\Delta E}{2q}$$

The Moscrop recorder, alluded to in § 182, exhibits the degree of unsteadiness during a single revolution by the width of the line which it draws On the other hand, any bending of the line implies the quite independent characteristic of unsteadiness from one revolution to another The former is due to insufficient fly-wheel energy, the latter to imperfect governing

190 An interesting consequence of the periodic alternations in crank-effort which occur in each revolution has been pointed out by Mr M Longridge[1] The fly-wheel receives its alternate acceleration and retardation through changes of the torsional stress in the shaft If these occur at intervals nearly equal to the period of free torsional vibration which the fly wheel possesses in virtue of the torsional elasticity of the shaft between it and the crank, strains of great amplitude will arise, and Mr Longridge has suggested that this may account for the observed fact that engine-shafts have been ruptured when running so that the fluctuations of crank effort occurred with one particular frequency, although the greatest effort was itself much less than the shaft would safely bear

XI Examples of Steam Engines

Stationary Engines

191 In classifying engines with regard to their general arrangement of parts and mode of working, account has to be taken of a considerable number of independent characteristics We have, first, a general division into *condensing* and *non-condensing engines*, with a subdivision of the condensing class into those which act by surface condensation and those which use injection Next there is the division into *compound* and *non-compound*, with a further classification of the former as double-, triple-, or quadruple-expansion engines Again, engines may be classed as *single* or *double-acting*, according as the steam acts on one or alternately on both sides of the piston Again, a few engines—such as steam-hammers and certain kinds of steam-pumps—are *non-rotative*, that is to say, the reciprocating motion of the piston does work simply on a reciprocating piece, but generally an engine does work on a continuously revolving shaft, and is termed *rotative* In most cases the crank-pin of the revolving shaft is connected directly with the piston-rod by a connecting-rod, and the engine is then said to be *direct-acting*, in other cases, of which the ordinary beam-engine is the most important example, a lever is interposed between the piston and the connecting-rod The same distinction applies to non-rotative pumping engines, in some of which the piston acts directly on the pump rod, while in others it acts through a beam The position of the cylinder is another element of classification, giving *horizontal*, *vertical*, and *inclined cylinder* engines Many vertical engines are further distinguished as belonging to the *inverted cylinder* class, that is to say, the cylinder is above the connecting-rod and crank In *oscillating cylinder engines* the connecting-rod is dispensed with, the piston-rod works on the crank-pin, and the cylinder oscillates on trunnions to allow the piston-rod to follow the crank-pin round its circular path In *trunk engines* the piston-rod is dispensed with, the connecting-rod extends as far as the piston, to which it is jointed, and a trunk or tubular extension of the piston, through the cylinder cover, gives room for the rod to oscillate In *rotary* engines there is no piston in the ordinary sense, the steam does work on a revolving piece, and the necessity is thus avoided of afterwards converting reciprocating into rotary motion Descriptive terms

192 In the single-acting atmospheric engine of Newcomen the beam was a necessary feature, the use of water-packing for the piston required that the piston should move down in the working stroke, and a beam was needed to let the counterpoise pull the piston up Watt's improvements made the beam no longer necessary, and in one of the forms he designed it was discarded—namely, in the form of pumping-engine known as the Bull engine, in which a vertical inverted cylinder stands over and acts directly on the pump-rod But the beam type was generally

[1] *Proc Inst Mech Eng*, May 1884, p 163

retained by Watt, and for many years it remained a favourite with builders of engines of the larger class The beam formed a convenient driver for pump-rods and valve-rods, and the parallel motion invented by Watt as a means of guiding the piston-rod, which could easily be applied to a beam-engine, was, in the early days of engine-building, an easier thing to construct than the plane surfaces which are the natural guides of the piston-rod in a direct-acting engine In modern practice the direct-acting type has to a very great extent displaced the beam type For mill driving and the general purposes of a rotative engine the beam type is now rarely chosen In pumping engines it is more common, but even there the tendency is to use direct-acting forms

Parallel motion in beam-engines

193 The only distinctive feature of beam engines requiring special notice here is the "parallel motion," an ordinary form of which is shown diagrammatically in fig 119 There MN is the path in which the piston-rod head, or crosshead, as it is often called, is to be guided ABC is the middle line of half the beam, C being the fixed centre about which the beam oscillates A link BD connects a point in the beam with a radius link ED, which oscillates about a fixed centre at E A point P in BD, taken so that BP DP EN CM, moves in a path which coincides very closely with the straight line MPN Any other point F in the line CP or CP produced is made to copy this motion by means of the links AF and FG, parallel to BD and AC In the ordinary application of the parallel motion a point such as F is the point of attachment of the piston-rod, and P is used to drive a pump-rod Other points in the line CP produced are occasionally made use of, by adding other links parallel to AC and BD [1]

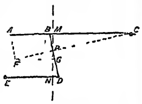

FIG 119 —Watt's Parallel Motion

Watt's linkage gives no more than an approximation to straight line motion, but in a well-designed example the amount of deviation need not exceed one four-thousandth of the length of stroke It was for long believed that the production of an exact straight-line motion by pure linkage was impossible, until the problem was solved by the invention of the Peaucellier cell [2] The Peaucellier linkage has not been applied to the steam-engine, except in isolated cases

Scott Russell's parallel motion

194 Another "parallel motion" which has been used in steam-engines is shown in fig 120 AB is a link pivoted on a fixed centre at A, and connected to the middle of another link PQ, which is twice the length of AB Q is guided to move in a straight line in the direction of AQ P then moves in an exact straight line through A This is not a pure linkage, since Q slides in a fixed guide, but the distance through which Q has to be guided is small compared with the stroke of P If Q is guided to move in the arc of a circle of large radius, by using a radius rod from a fixed centre above or below it, the guiding surfaces at Q are avoided, but the path of P is then only very nearly straight An example of the linkage in this form, with the further modification that A is shifted out, and B is brought nearer to P, occurs in the pumping engine of fig 130 below

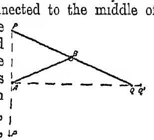

FIG 120

In by far the greater number of modern steam-engines the crosshead is guided by a block sliding on planed surfaces In many beam-engines, even, this plan of guiding the piston has taken the place of the parallel motion.

Horizontal direct acting engines.

195 No type of steam engine is so common as the horizontal direct-acting A small engine of this type, made by Messrs Tangye, and rated as a 10 horse power engine, is illustrated in figs 121 to 124 It furnishes a good example of a very numerous class, and serves to illustrate the principal parts of a complete engine Fig 121 is a side elevation, fig 122 a plan, fig 123 a transverse section through the bedplate in front of the cylinder, on the line

1 The kinematics of the parallel motion are discussed in Rankine's *Machinery and Mill Work*, p 275, and rules are given for the proportions and positions of the parts

2 See Kempe's *How to Draw a Straight Line* ("Nature Series,"), 1877.

AB, and fig 124 is a horizontal section through the cylinder, valve chest, valve, stuffing boxes, piston, and crosshead The bedplate

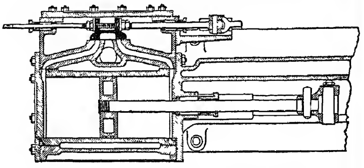

FIG 124 —Horizontal Section through Cylinder and Valve Chest

is a single hollow casting, with two surfaces planed on it to serve as guides (see fig 123) At one end the bedplate forms a pillow block for the shaft, which has another main bearing independently supported beyond the fly wheel At the other end the bedplate is shaped so as to form the cylinder cover, the cylinder is bolted to this and overhangs the bed

Details The cylinder (of 10 inches diameter and 20 inches stroke) consists of an internal "liner" of cast iron, exactly bored, and fitted within an external cylindrical casting, of which the ports and sides of the valve chest form part The space between the liner and the external cylinder serves as a steam-jacket The use of a separate liner within the main cylinder is now general in large engines In the front cylinder cover there is a stuffing-box through which the piston rod passes The stuffing-box is kept steam tight by a soft packing which is pressed in by a gland In some instances the packing consists of metallic rings The cylinder cover and gland are lined with a brass ring in the hole through which the piston-rod passes The valve rod is brought out of the valve chest in the same way The piston is a hollow casting into which the piston rod is screwed and riveted over It is packed by two split rings of cast iron, which are sprung into recesses turned in the circumference of the piston This mode of packing is used in locomotives and small engines For large pistons the usual plan is to employ wider split rings, called floating rings, pressed against the sides of the cylinder, not by their own elasticity, but by separate springs behind them in the body of the piston, they are held in place by a movable flange called a junk-ring on one face of the piston One example of the packing of a large piston is shown in fig 134 The crosshead consists of a steel centre piece with a round boss, in which the piston rod is secured by a cotter, and a forked front, where the end of the connecting-rod works on a pin A pair of pins at top and bottom carry the steel shoes or sliding-blocks, whose distance from the centre is adjustable by nuts to take up wear There is no crank, the connecting-rod works on a pin fixed in a disk on the end of the shaft in front of the main bearing The valve-rod, which is worked by an eccentric just behind the bearing, is extended through the end of the valve-chest, and forms the plunger of a feed pump which is bolted to the end of the chest Frequently the feed-pump is fixed at any convenient part of the bedplate, and is driven by a separate eccentric, and in some cases its plunger is connected directly to the crosshead In the main bearing the shaft turns in gun-metal or phosphor-bronze blocks called brasses In heavy engines these are generally lined with Babbit's anti friction metal or other soft alloy, and in many modern engines the brasses are entirely dispensed with, a lining of Babbit's metal being let into the cast-iron surface of the bearing When the brasses are in two pieces, the plane of division between them is chosen to be that in which the wear is likely to be least A more satisfactory adjustment is possible when the brasses are in three or more pieces

Condenser and air-pump 196 When a condenser is used with a small horizontal engine it is usually placed behind the cylinder, and the air-pump, which is

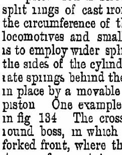

Fig 125

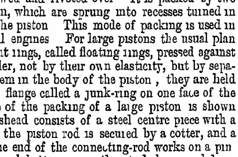

Fig 126

Condenser and Air Pump

within the condenser, is a horizontal plunger or piston-pump worked by a "tail rod"—that is, a continuation of the piston-rod past the piston and through the back cover of the cylinder Figs 125 and 126 show in section one of Messrs Tangye's small condensers fitted with a double-acting air-pump to be driven by a tail rod The condenser proper is the chamber A, and into it the injection-water streams continuously through perforations in the pipe B, which has a cock outside to regulate the supply The pump draws condensed water down to the lower part of the vessel at either end alternately through the valves C, and forces it up thence through the valves D to a chamber E, from which the delivery pipe leads out The pump is a gun metal piston working in a cylinder fitted with a gun metal liner The valves are flat india-rubber rings held down in the centre by a spring, which allows them to open by rising bodily, as well as by bending

197 The engine of figs 121–4 makes 85 revolutions per minute, and its mean piston speed is consequently about 280 feet per minute In some special forms of small horizontal engine the design is adapted to a much more rapid reciprocation of the moving masses, and the piston speed is raised to a value seldom exceeded in the largest land engines, although still higher values are now common in marine practice Experience shows that the weight of engines of any one type varies roughly as the piston area Their power depends on the product of piston area, piston speed, and pressure, and hence, so long as the pressures are similar, the ratio of power to weight is nearly proportional to piston speed Cases present themselves in which it is desirable to make this ratio as great as possible, and, apart from this, an engine making a large number of revolutions per minute is a convenient motor for certain high speed machines High speed horizontal engines

A good example of a small horizontal engine, specially designed by the symmetry and balance of its parts, by largeness of the bearing surfaces, and by very perfect lubrication, to stand the strains which are caused by high speed, is the Armington & Sims engine, made in America by the patentees and in England by Messrs Greenwood & Batley The bedplate is symmetrical about the line of motion of the crosshead, it supplies two very long main bearings for the shaft, at each end of which there is an overhung fly wheel The bearings have an adjustable side block to take up wear They are formed entirely of white-metal, cast on to the cast iron pillow blocks In the middle are two disks, forming crank cheeks, which are weighted opposite the crank pin, so that they balance the pin and that part of the connecting-rod which may be treated as having its mass applied there The crank pin and the crosshead pin are wide enough to give a large bearing area The crosshead block is a hollow bronze casting, giving an exceptionally large surface of contact with the guides The valve is a piston-valve of the Trick type, which works sufficiently tight without packing The valve rod and eccentric rod are connected through a block which slides on a fixed guide The governor, which has been already illustrated in fig 100, is contained within one of the fly-wheels An engine of this type, with a cylinder 12 inches in diameter and a stroke of 12 inches, makes 275 revolutions per minute, has a piston speed of 550 feet per minute, and indicates about 80 horse power Other good examples of high speed combined with double action are furnished by the Porter Allen engine[1] and by the very light engines which Mr Thorneycroft and others have introduced for driving fans to supply air to the closed stokeholes of torpedo boats In these a speed of 1000 revolutions per minute is made possible by the use of light reciprocating parts and large bearing surfaces Armington and Sims engine

198 Fig 127 shows a large non-compound horizontal Corliss engine for mill driving, by Messrs Hick, Hargreaves, & Co The cylinder is 34 inches in diameter, the stroke 8 feet, and the speed 45 revolutions per minute, giving a mean piston speed of 720 feet per minute The cylinder is steam-jacketed round the barrel in the space between the liner and the outer cylinder, and also at the ends, which are cast hollow for this purpose In large horizontal engines the weight of the piston tends to cause excessive wear on the lower side of the cylinder In the example shown a part of the weight is borne by a tail-rod, ending in a block, which slides on a fixed guide behind the cylinder To further diminish wear the piston is sometimes made much wider from front to back than the one shown here, and the device is sometimes resorted to of giving the piston rod "camber"—that is to say, an upward curvature in the middle portion, which the weight of the piston reduces to straightness Fig 127 illustrates a common method of attaching the air pump and condenser in large horizontal engines The condenser is placed in a well in front of the cylinder, and the air pump, which is a vertical bucket-pump, is worked by a bell crank lever, connected with the crosshead by a link The fly-wheel of this engine is grooved for rope-gearing, it is cast in segments, which are bolted to one another and to the spokes, and the spokes are secured by cotters in tapered sockets in the nave It is large and heavy, to suit the inequality of driving effort which is caused by the use of a single cylinder and a very early cut off in engines of this class To facilitate starting and valve setting, mill engines are often provided with an auxiliary called a "barring" engine The barring engine turns a toothed pinion, which gears into a toothed rim in the fly wheel, and is contrived to fall automatically out of gear as soon as the main engine starts Large horizontal Corliss engine

[1] *Proc Inst Mech Eng*, 1868

Coupled engines. 199. When uniformity of driving effort or the absence of dead points is specially important, two independent cylinders are often coupled to the same shaft by cranks at right angles to each other, an arrangement which allows the engine to be started readily from any position. The ordinary locomotive is an example of this form. Among fixed engines of the larger kind, *winding engines*, in which ease of starting, stopping, and reversing is essential, are very generally made by coupling a pair of horizontal cylinders, with cranks at right angles to each other, on opposite sides of the winding drum, with the link motion as the means of operating the valves.

Compound horizontal engines. 200. Non-compound engines of so large a size as that of fig. 127 are comparatively uncommon. Horizontal engines of the larger class are generally compounded either (1) by having a high and a low pressure cylinder side by side, working on two cranks at exactly or nearly right angles to each other, or (2) by placing one cylinder behind the other, with the axes of both in the same straight line. The latter is called the *tandem* arrangement. In it one piston rod is generally common to both cylinders; occasionally, however, the piston-rods are distinct, and are connected to one another by a framing of parallel bars outside of the cylinders. Another construction, rarely followed, is to have parallel cylinders with both piston rods acting on one crank by being joined to opposite ends of one long crosshead. In some recent compound engines the large cylinder is horizontal, and the other lies above it in an inclined position, with its connecting rod working on the same crank-pin.

In tandem engines, since the pistons move together, there is no need to provide a receiver between the cylinders. It is practicable to follow the "Woolf" plan of allowing the steam to expand directly from the small into the large cylinder, and in many instances this is done. In point of fact, however, the connecting-pipe and steam chest form an intermediate receiver of considerable size, which will cause loss by "drop" (§ 113) unless steam be cut off in the large cylinder before the end of the stroke. Hence it is more usual to work with a moderately early cut off in the low-pressure cylinder than to use the "Woolf" plan of admitting steam to it throughout the whole stroke. Unless it is desired to make the cut off occur before half stroke, a common slide valve will serve to distribute steam to the large cylinder. For an earlier cut-off than this a separate expansion valve is required on the low pressure cylinder, to supplement the slide valve; and in any case, by providing a separate expansion valve, the point of cut-off is made subject to easy control, and may be adjusted so as to avoid drop or to divide the work as may be desired between the two cylinders.[1] For this reason it is not unusual to find an expansion valve, as well as a common slide valve, on the low-pressure cylinder even of tandem engines. In many cases, however, the common slide valve only is used. On the high pressure cylinder

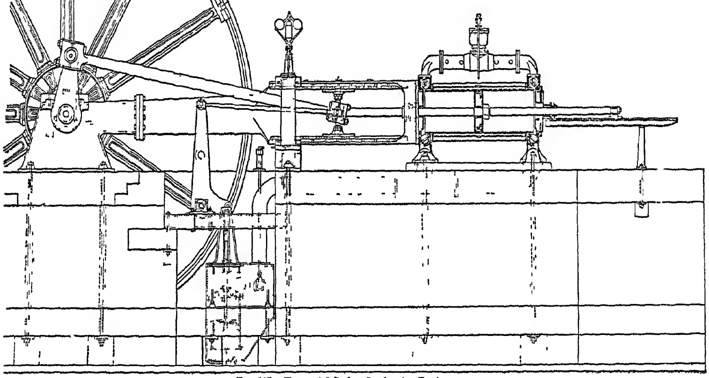

FIG. 127.—Horizontal Corliss Condensing Engine.

of compound engines, the cut off is usually effected either by an expansion slide valve or by some form of Corliss or other trip gear.

For mill engines the compound tandem and compound coupled types are now the most usual, and the high pressure cylinder is very generally fitted with Corliss gear. In the compound coupled arrangement the cylinders are on separate bedplates, and the fly wheel is between the cranks.

Direct acting vertical cylinder engine. 201. The general arrangement of vertical engines differs little from that of horizontal engines. The cylinder is usually supported above the shaft by a cast iron frame resembling an inverted A, whose sides are kept parallel for a part of their length to serve as guides for the crosshead. Sometimes one side of the frame only is used, and the engine is stiffened by a wrought iron column between the cylinder and the base on the other side. *Wall engines* are a vertical form with a flat frame or bedplate, which is made to be bolted against a wall; in these the shaft is generally at the top. Vertical engines are compounded, like horizontal engines, either by coupling parallel cylinders to cranks at right angles (as in the ordinary marine form, which will be illustrated later, § 218), or, tandem fashion, by placing the high pressure cylinder above the other. In vertical condensing engines the condenser is situated at the base, and the air pump, which has a vertical stroke, is generally worked by a lever connected by a short link to the crosshead. In some cases the pump is horizontal, and is worked by a crank on the main shaft.

High-speed single-acting engines. 202. Engines making 400 to 1600 revolutions per minute have been extensively applied, in recent years, to the driving of dynamos and other high-speed machines. These are for the most part single acting; steam is admitted to the back of the piston only, and the connecting rod is in compression throughout the whole revolution. Besides simplifying the valves, this has the important advantage that alternation of strain at the joints may be entirely avoided, with the knocking and wear of the brasses which it is apt to cause. To secure, however, that the connecting-rod shall always push, there must be much cushioning during the back or exhaust stroke. From a point near the middle of the back stroke to the end the piston is being retarded; and, as this must not be done by the rod (which would thereby be required to pull), cushioning must begin there, and the work spent upon the cushion must at every stage be at least as great as the loss of energy on the part of the piston and rod. In some single acting engines this cushioning is done by compressing a portion of the exhaust steam; in others the rod is kept in compression by help of a supplementary piston, on which steam from the boiler presses; in Mr Willans's engine the cushioning is done by compressing air.

Brotherhood engine. 203. A very successful example of the multiple cylinder single acting high speed type is the three cylinder engine introduced by Mr Brotherhood in 1873, the most recent form of which is shown in figs. 128 and 129. Fig. 128 is a longitudinal and fig. 129 a transverse section. Three cylinders, set at 120° apart, project from a closed casing, the central portion of which forms the exhaust. The pistons are of the trunk type—that is to say, there is a joint in the piston itself which allows the piston rod to oscillate, and so makes a separate connecting rod unnecessary. The three rods work on a single crank-pin, which is counterbalanced by masses

[1] Or, alternatively, the adjustment may be made so that the steam undergoes equal changes of temperature in both cylinders.

fixed to the crank cheeks on the other side of the shaft. Steam is admitted to the back of the pistons only. It passes first through a throttle valve, which is controlled by a centrifugal spring governor (fig. 128), and is then distributed to the cylinders by three piston-valves A, worked by an eccentric, the sheave of which is made hollow so as to overhang one of the main bearings (fig. 128). Release takes place by the piston itself uncovering exhaust ports in the circumference of the cylinder, and the rocking motion of the

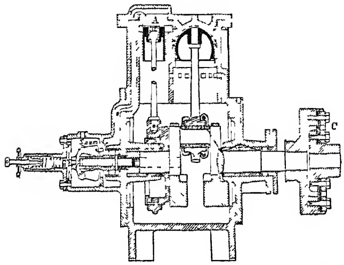

FIG. 128.—Brotherhood's Three Cylinder Engine: longitudinal section.

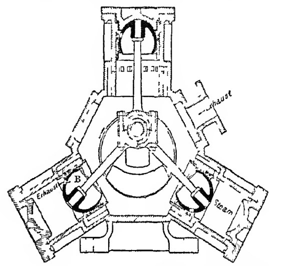

FIG. 129.—Brotherhood's Three Cylinder Engine: transverse section.

piston rod is taken advantage of to open a supplementary exhaust port (B, fig. 129), which remains open during a sufficient portion of the back stroke. The flexible coupling C shown in fig. 128, in which the twisting moment of the shaft is transmitted through disks of leather, prevents straining of the shaft and bearings through any want of alignment between the shaft of the engine and that of the mechanism it drives. Besides its use as a steam engine, Mr Brotherhood's pattern has been extensively applied in driving torpedoes by means of compressed air. As a steam engine it is compounded by placing a high pressure cylinder outside of and tandem with each low-pressure cylinder.

204. In other engines of this type a pair of cylinders, or a high and a low pressure cylinder, are set vertically side by side, to work on cranks opposite each other. The cranks and connecting-rods are completely enclosed, and are lubricated by dipping into a mixture of oil and water with which the lower part of the casing is filled. In the Westinghouse engine, where there are two vertical cylinders to which steam is admitted by a piston-valve, the crank shaft is situated half a crank's length out of the line of stroke, to reduce the effects of the connecting-rod's obliquity during the working stroke.[1] In Mr Willans's latest form of engine the high and low pressure cylinders are tandem, and the space between the pistons forms an intermediate receiver. The piston-rod is hollow, and has a piston valve in it which controls the admission of steam to the high-pressure cylinder and its transfer to the low-pressure cylinder. The piston-valve within the rod takes its differential motion from an eccentric on the crank-pin. The crosshead is itself a piston working in a cylindrical guide, in which it compresses air as it rises during the back stroke in order to cushion the reciprocating parts.[2]

Pumping engines. 205. In engines for pumping or for blowing air it is not essential to drive a revolving shaft, and in many forms the reciprocating motion of the steam-piston is applied directly or through a beam to produce the reciprocating motion of the pump piston or plunger. On the other hand, pumping engines are frequently made rotative for the sake of adding a fly-wheel. When the level of the suction water is sufficiently high, horizontal engines, with the pump behind the cylinder and in line with it, are generally preferred; in other cases a beam engine or vertical direct-acting engine is more common. Horizontal engines are, however, employed to pump water from any depth by using triangular rocking frames, which serve as bell-crank levers between the horizontal piston and vertical pump-rods.[3]

Fig. 130 shows a compound inverted vertical pumping engine of the non-rotative class, by Messrs Hathorn, Davey, & Co. Steam is distributed through lift valves, and the engine is governed by the differential gear illustrated in fig. 107, in conjunction with a cataract, which makes the pistons pause at the end of each stroke. The pistons are in line with two pump-rods, and are coupled by an inverted beam which gives guidance to the crossheads by means of an approximate straight-line motion, which is a modification of that of fig. 120. Surface condensers are frequently used with pumping engines, the water which the engine pumps serving as circulating water.

Direct-acting steam-pumps. 206. In a very numerous class of direct-acting steam-pumps, the steam-piston and the pump-piston or plunger are on the same piston-rod. In some of these a rotative element is introduced, partly to secure uniformity of motion, and partly for convenience of working the valves; a connecting rod is taken from some point in the piston rod to a crank shaft which carries a fly-wheel; or a slotted crosshead fixed to the rod gives rotary motion to a crank-pin gearing into the slot, the line of the slot being perpendicular to that of the stroke. Many other steam pumps are strictly non-rotative. In some the valve is worked by tappets from the piston-rod. In the Blake steam-pump a tappet worked by the piston as it reaches each end of its stroke throws over an auxiliary steam valve, which

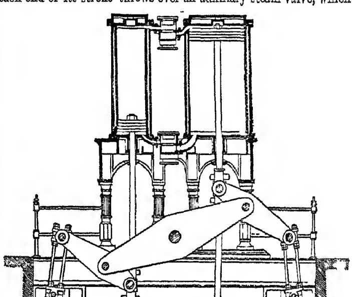

FIG. 130.—Vertical Non-Rotative Pumping Engine.

admits steam to one or other side of an auxiliary piston carrying the main slide-valve. In Cameron & Floyd's form one of a pair of tappet-valves at the ends of the cylinder is opened by the piston as it reaches the end of the stroke, and puts one or other side of an auxiliary piston, which carries the slide valve, into communication with the exhaust, so that it is thrown over. In the Worthington engine—a design which has had much success in America, and is now being introduced in England by Messrs Simpson—two steam cylinders are placed side by side, each working its own pump-piston. The piston-rod of each is connected by a short link to a swinging bar, which actuates the slide valve of the other steam cylinder. In this way one piston begins its stroke when the motion of the other is about to cease, and a smooth and continuous action is secured.

207. The Worthington engine has been extensively applied, on a large scale, to raise water for the supply of towns and to force oil through "pipe lines" in the United States. In the larger sizes it is made compound, each high pressure cylinder having a low pressure cylinder tandem with it on the same rod. Owing to the lightness of the reciprocating masses, and their comparatively slow acceleration, their inertia does not compensate, to any great extent, for the inequality of pressure on the pump piston that would be caused by an early cut off in the steam cylinder (see § 186). To meet this difficulty, and make high expansion practicable, an ingenious addition has recently been made to the engine.[4] A crosshead A (fig. 131) fixed to each of the piston rods is connected to the piston rods of a pair of oscillating cylinders B, B, which contain water and communicate with a reservoir full of air compressed to a pressure of about 300 ℔ per square inch. When the stroke (which Worthington engines.

takes place in the direction of the arrow) begins the pistons are at first forced in, and work is at first done by the main piston rod, through the compensating cylinders B, B, on the compressed air in the reservoir. This continues until the crosshead has advanced so that the cylinders stand at right angles to the line of stroke. Then for the remainder of the stroke the compensating cylinders assist in driving the main piston, and the compressed air gives out the energy which it stored in the earlier portion. The volume of the air reservoir is so much greater than the volume of the cylinders B, B that the air

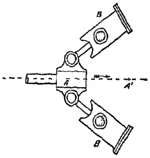

Fig 131

pressure remains nearly constant throughout the stroke. Any leakage from the cylinder or reservoir is made good by a small pump which the engine drives. One advantage which this method of equalizing the effort of a steam engine piston has (as compared with making use of the inertia of the reciprocating masses) is that the effort, when adjusted to be uniform at one speed, remains uniform although the speed be changed, provided the inertia of the reciprocating parts be small. In the Worthington "high duty" engine, where this plan is in use, the high and low pressure cylinders are each provided with a separate expansion valve of the rocking-cylinder type, as well as a slide-valve; the cut off is early, and the efficiency is as high as in other pumping engines of the best class.

The pulsometer. 208. Mr Hall's "pulsometer" is a peculiar pumping engine without cylinder or piston, which may be regarded as the modern representative of the engine of Savery (§ 6). The sectional view, fig 132, shows its principal parts. There are two chambers A, A', narrowing towards the top, where the steam pipe B enters. A ball valve C allows steam to pass into one of the chambers and closes the other. Steam entering (say) the right hand chamber forces water out of it past the clack valve V into a delivery passage D, which is connected with an air vessel. When the water level in A sinks so far that steam begins to blow through the delivery passage, the water and steam are disturbed and so brought into intimate contact, the steam in A is condensed, and a partial vacuum is formed. This causes the ball-valve C to rock over and close the top of A, while water rises from the suction-pipe E to fill that chamber. At the same time steam begins to enter the other chamber A', discharging water from it, and the same series of actions is repeated in either chamber alternately. While the water is being driven out there is comparatively little condensation of steam, partly because the shape of the vessel does not promote the formation of eddies, and partly because there is a cushion of air between the steam and the water. Near the top of each chamber is a small air valve opening inwards, which allows a little air to enter each time a vacuum is formed. When any steam is condensed, the air mixed with it remains on the cold surface and forms a non conducting layer. The pulsometer is, of course, far from efficient as a thermodynamic engine, but its suitability for situations where other steam pumps cannot be used, and the extreme simplicity of its working parts, make it valuable in certain cases.

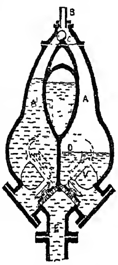

Fig 132.—Pulsometer

Davey's safety motor. 209. We have seen that the tendency of modern steam practice is towards higher pressures, and that this means a gain both in efficiency and in power for a given weight of engine. High pressure, or indeed any pressure materially above that of the atmosphere, is out of the question when engine and boiler are to work without the regular presence of an attendant. Mr Davey has recently introduced a domestic motor which deserves notice from the fact that it employs steam at atmospheric pressure. One form of this successful little engine is shown in fig 133. The boiler—which serves as the frame of the engine—is of cast iron, and is fitted with a cast iron internal fire box, with a vertical flue which is traversed by a water bridge. The cylinder, which is enclosed within the upper part of the boiler, and the piston are of gun metal, and work without lubrication. Steam is admitted by an ordinary slide-valve, also of gun metal, worked by an eccentric in the usual way. The condenser stands behind the boiler; it consists of a number of upright tubes in a box, through which a current of cold water circulates from a supply pipe at the bottom to an overflow pipe at the top. In larger sizes of the motor the cylinder stands on a distinct frame, and the boiler has a hopper fire box, which will take a charge of coke sufficient to drive the engine for several hours without attention. About 6 or 7 lb of coke are burned per horse power per hour.

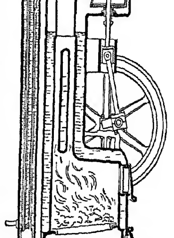

Fig 133.—Davey Motor

Rotary engines. 210. From the earliest days of the rotative engine attempts have been made to avoid the intermittent reciprocating motion which an ordinary piston-engine first produces and then converts into motion of rotation. Murdoch, the contemporary of Watt, proposed an engine consisting of a pair of spur wheels gearing with one another in a chamber through which steam passed by being carried round the outer sides of the wheels in the spaces between successive teeth.[1]

In a more modern wheel engine (Dudgeon's) the steam was admitted by ports in side plates into the clearance space behind teeth in gear with one another, just after they had passed the line of centres. From that point to the end of the arc of contact the clearance space increased in volume, and it was therefore possible, by stopping the admission of steam at an intermediate point, to work expansively. The difficulty of maintaining steam-tight connexion between the teeth and the side plates on which the faces of the wheels slide is obvious, and the same difficulty has prevented the success of many other forms of rotary engine. These have been devised in immense variety in many cases, it would seem, with the idea that a distinct mechanical advantage was to be secured by avoiding the reciprocating motion of a piston.[2] In point of fact, however, very few forms entirely escape having pieces with reciprocating motion. In all rotary engines, with the exception of steam turbines,—where work is done by the kinetic impulse of steam,—there are steam chambers which alternately expand and contract in volume, and this action usually takes place through a more or less veiled reciprocation of working parts. So long as engines work at a moderate speed there is little advantage in avoiding reciprocation; the alternate starting and stopping of piston and piston rod does not affect materially the frictional efficiency, throws no deleterious strain on the joints, and need not disturb the equilibrium of the machine as a whole. The case is different when very high speeds are concerned; it is then desirable as far as possible to limit the amount of reciprocating motion and to reduce the masses that partake in it.

Tower's spherical engine. 211. A recent interesting and successful example of the rotary type is the spherical engine of Mr Beauchamp Tower,[3] which, like several of its predecessors,[4] is based on the kinematic relations of the moving pieces in a Hooke's joint. Imagine a Hooke's joint, uniting two shafts set obliquely to one another, to be made up of a central disk to which the two shafts are hinged by semicircular plates, each plate working in a hinge which forms a diameter of the central disk, the two hinges being on opposite sides of the disk and at right angles to one another. Further, let the disk and the hinged pieces be enclosed in a spherical chamber through whose walls the shafts project. As the shafts revolve each of the four spaces bounded by the disk, a hinged piece, and the chamber wall will suffer a periodic increase and diminution of volume, between limits which depend on the angle at which the shafts are set. In Mr Tower's engine this arrangement is modified by using spherical sectors, each a quarter sphere, in place of semicircular plates, for the pieces in which the shafts terminate. The shafts are set at 135°. Each of the four enclosed cavities then alters in volume from zero to a quarter sphere, back to zero, again to a quarter sphere, and again back to zero, in a complete revolution of the shafts. In practice the central disk is a plate of finite thickness, whose edge is kept steam tight in the enclosing chamber by spring packing, and the sectors are reduced to an extent corresponding to the thickness of the central disk. One shaft is a dummy and runs free, the other is the driving-shaft. Steam is admitted and exhausted by ports in the spherical sectors, whose backs serve as revolving slide valves. It is admitted to each cavity during the first part of each periodical increase of the cavity's volume. It is then cut off and allowed to expand as the cavity further enlarges, and is exhausted as the cavity contracts. If the working shaft, to which the driven mechanism serves as a fly wheel, revolves uniformly, the dummy shaft is alternately accelerated and retarded. Apart from this, the only reciprocating motion is the small amount of oscillation which the comparatively light central disk undergoes.

Another rotary engine of the Hooke's joint family is Mr Field-

[1] See Farey's *Treatise on the Steam Engine*, p 676.

[2] A large number of proposed rotary engines are described, and their kinematic relations to one another are discussed, in Reuleaux's *Kinematics of Machinery*, translated by Prof Kennedy.

[3] *Proc Inst Mech Eng*, March 1885.

[4] One of these, the disk engine of Bishop, was used for a time in the printing office of *The Times*, but was discarded in 1857.

ing's,[1] in which a gimbal ring and four curved pistons take the place of the disk Two curved pistons are fixed on each side of the gimbal-ring, and as the shafts revolve these work in a corresponding pair of cavities, which may be called curved cylinders, fixed to each shaft

Steam turbines

212 Attempts have been made from time to time to devise steam engines of the turbine class, where rotation of a wheel is produced either by reaction from a jet of escaping steam or by impact of a jet upon revolving blades A revolving piece which is to extract even a respectable fraction of the kinetic energy of a steam jet must move with excessive velocity In Mr C A Parsons's steam turbine this difficulty is overcome and a moderate degree of efficiency is secured by using a series of central flow turbine wheels, in the form of perforated disks, all on one shaft, with fixed disks between which are perforated to serve as guide blades Steam passes from end to end of the series, giving up a small portion of its energy to each, but retaining little at the end

XII MARINE ENGINES

Types of marine engines

213 The early steamers were fitted with paddle-wheels, and the engines used to drive them were for the most part modified beam engines Bell's "Comet" (§ 21) was driven by a species of inverted beam-engine, and another form of inverted beam, known as the side-lever engine, was for long a favourite with marine engineers In the side-lever engine the cylinder was vertical, and the piston rod projected through the top From a crosshead on the rod a pair of links, one on each side of the cylinder, led down to the ends of a pair of horizontal beams or levers below, which oscillated about a fixed gudgeon at or near the middle of their length The two levers were joined at their other ends by a crosstail, from which a connecting rod was taken to the crank above The side-lever engine is now obsolete

Side-lever engines

Beam-engines

In American practice, engines of the beam type, with a braced-beam supported on A frames above the deck, are still common in river-steamers and coasters

Steeple-engines

214 An old form of direct acting paddle engine was the steeple-engine, in which the cylinder was set vertically below the crank Two piston-rods projected through the top of the cylinder, one on each side of the shaft and of the crank They were united by a crosshead sliding in vertical guides, and from this a return-connecting-rod led to the crank

Oscillating engines

215 Modern paddle-wheel engines are usually of one of the following types (1) In *oscillating cylinder engines* the cylinders are set under the crank-shaft, and the piston-rods are directly connected to the cranks The cylinders are supported on trunnions which give them the necessary freedom of oscillation to follow the movement of the crank Steam is admitted through the trunnions to slide-valves on the sides of the cylinders In some instances the mean position of the cylinders is inclined instead of vertical, and oscillating engines have been arranged with one cylinder before and another behind the shaft, both pistons working on one crank The oscillating cylinder type is best adapted for what would now be considered comparatively low pressures of steam (2) *Diagonal engines* are direct-acting engines of the ordinary connecting-rod type, with the cylinders fixed on an inclined bed and the guides sloping up towards the shaft

Diagonal engines

216 When the screw-propeller began to take the place of paddle-wheels in ocean-steamers, the increased speed which it required was at first supplied by using spur-wheel gearing in conjunction with one of the forms of engines then usual in paddle steamers After a time types of engine better suited to the screw were introduced, and were driven fast enough to be connected directly to the screw-shaft The smallness of the horizontal space on either side of the shaft formed an obstacle to the use of horizontal engines, but this difficulty was overcome in several ways In Penn's trunk-engine, still used in the navy, the engine is shortened by attaching the connecting rod directly to the piston, and using a hollow piston-rod, called a trunk, large enough to allow the connecting rod to oscillate inside it The trunk extends through both ends of the cylinder and forms a guide for the piston It has the drawback of requiring very large stuffing-boxes, of wasting cylinder space, and of presenting a large surface of metal to alternate heating by steam and cooling by contact with the atmosphere The use of high-pressure steam is likely to make the trunk engine obsolete

Trunk engines

[1] *Min Proc Inst C E*, November 1885

Return-connecting rod engines

217 The return-connecting rod engine is another horizontal form much used in the navy It is a steeple engine placed horizontally, with two, and in some cases four, piston-rods in each cylinder The piston-rods pass clear of the shaft and the crank, and are joined beyond it in a guided crosshead, from which a connecting-rod returns

Horizontal direct-acting engines

Ordinary horizontal direct acting engines with a short stroke and a short connecting-rod are also common in warships, where the horizontal is frequently preferred to the vertical type of engine for the sake of keeping the machinery below the water-line In horizontal marine engines the air-pump and condenser are generally placed on the opposite side of the shaft from the cylinder, which balances the weight and allows the air-pump to be driven direct

Inverted vertical engines

218 In merchant ocean-steamers one general type of engine is universal, and the same type is now to an increasing extent adopted in naval practice This is the inverted vertical direct acting engine, generally with two or more cylinders placed side by side directly over the shaft In exceptional cases a single cylinder has been used, with a fly-wheel on the shaft Two, three, and four cylinders are common

Example.

The most usual form of existing marine engine is the two cylinder compound arrangement, with cranks at right angles or nearly at right angles, of which figs 135, 136, 137 (pp 518-20) show a characteristic example (the engines of the s s "Tartar," by Messrs John & James Thomson, Glasgow)

Fig 135 is an end elevation, fig 136 a longitudinal section through the centre of the engines, and fig 137 a thwart ship section through the condenser and air pump The cylinders are 50 and 94 inches in diameter, and the stroke is 5 feet Both cylinders are fitted with liners, and are steam jacketed Double ported slide-valves are used on both, and the high pressure valve has a relief-ring The crosshead guides are fitted on the side on which the crosshead bears when the engines are going ahead, with a hollow box behind the guiding surface, and cold water is kept circulating in this to prevent the guides from heating

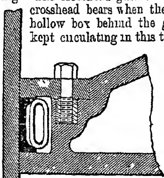

FIG 134—Piston Packing

The crank shaft is of Vicker's steel, $17\frac{1}{2}$ inches in diameter The condenser is in the place it usually has in engines of this type,—in the lower part of the back frame, with its tubes running horizontally from end to end of the engine There are 1400 tubes, of 1 inch diameter and $1\frac{1}{2}$ inch pitch The air-pumps are of the single-acting bucket kind, and are driven by a lever from the crosshead Centrifugal circulating pumps are used, driven by a pair of independent small vertical engines The link-motion is worked by steam starting and reversing gear, which appears on the left side of the engine in fig 135 These engines work with a boiler pressure of 90 lb, and indicate 3560 horse-power Fig 134 shows, on a larger scale, the piston packing, which consists of a pair of floating rings, pressed out by a spiral spring behind them

Tandem vertical engines.

219 Two other arrangements of double compound (as distinguished from triple expansion) marine engines of the inverted vertical type require notice One is the tandem arrangement, largely adopted in the steamers of the "White Star" line In these each crank is operated by an independent pair of compound cylinders, the high pressure cylinder being on top of the low pressure cylinder, with one piston rod common to both The valves of both are worked by a single pair of eccentrics with a link-motion, the valve rod of the low-pressure cylinder extends through the top of its valve chest, and is joined either directly or by a short lever with the valve rod of the high-pressure cylinder Generally two pairs of tandem cylinders are placed side by side, one pair abaft the other, to work on cranks at right angles In exceptionally large engines three pairs have been used, working on

cranks 120° apart,[1] an arrangement greatly superior to that of two cranks in uniformity of effort on the shaft. To facilitate removing the pistons from the cylinders, the large cylinder has in some cases been set above the other.

Three cylinder arrangement

220. The other arrangement of double compound marine engine has three cylinders set in line fore and aft. The middle one is the high pressure cylinder; the other two receive steam from it, and form together the equivalent of one large low pressure cylinder. The three work on cranks at 120° apart. Besides securing the advantage in uniformity of effort which three cranks have over two, this form avoids the use, in very powerful engines, of a low pressure cylinder of excessive size. On the other hand, the three cylinder form takes up more space, and has a larger number of working parts. In the most powerful engines that have yet been constructed this three cylinder arrangement is followed. The "Umbria" and "Etruria" have a 71 inch high pressure cylinder between two 105 inch low-pressure cylinders, with a stroke of 6 feet. These engines, which were built just before the introduction of triple expansion, are supplied with steam at a pressure of 110 lb by gauge, and indicate 14,300 horse power.

In this and in the ordinary two-cylinder form of marine engine, the low pressure valve chest and the casing of the engine between the cylinders form an intermediate receiver for the steam.

Triple expansion engines

221. During the last two or three years a great advance has taken place in marine engineering by the general introduction of triple expansion engines, and by an increase in steam pressure which the system of triple expansion makes practicable. In 1874 the steamer "Propontis" was fitted with a set of three crank triple expansion engines, designed by Mr A. C. Kirk. The experiment was prevented from being fully successful by the failure of the boilers, which were of a special type. Another experiment with triple engines in the yacht "Isa" in 1877 prepared the way for their application to regular ocean service. In 1882 the steamship "Aberdeen," with triple engines designed by Mr Kirk, to work with steam of 125 lb pressure, supplied from double ended steel boilers of the ordinary marine type, demonstrated the advantage and safety of the system. Since then its use has become general in new steamers, and in many cases the older double engines are being removed to give place to engines of the triple-expansion type, with the effect of reducing the consumption of coal by about 25 per cent.[2]

222. In the most common arrangement of triple expansion engines three cylinders are ranged in line, fore and aft, working on cranks at 120° apart. Piston valves are generally preferred, and these are not uncommonly worked by some form of radial valve gear instead of the ordinary link-motion. An advantage of this is that the space which would be taken up by eccentrics upon the shaft is saved, and longer main bearings are in consequence possible, without spreading the engines in the fore-and-aft direction. An objectionable feature of the three cylinder triple engine is its length; on the other hand, the high speed and high pressure which are features of modern practice make long bearings indispensable.

223. To avoid the length of the three crank engine, Mr Brock and others have made engines of the triple expansion type with two cranks, by putting the high and the intermediate pressure cylinders above and tandem with two low pressure cylinders. Mr Brock has also built four cylinder *quadruple* expansion engines of a similar form (with two cranks), and estimates that they show an economy in coal consumption of 5 per cent as compared with triple-expansion engines working with the same pressure of steam.

Quadruple expansion engines

224. Steam jackets are retained by some but not by all builders; where they are employed the boiler steam is usually reduced in pressure before admission to the intermediate and low pressure cylinder jackets and to the receiver-jackets. The feed water is frequently heated to about 200° F. by Weir's plan of condensing in it, by common injection, a quantity of steam taken from the second receiver; this has the advantage of freeing it of air, and of preventing local chilling in the boiler. In present day practice the boiler pressure, for a triple expansion engine, ranges from 120 to 170 lb per square inch (by gauge), and it does not appear that any material increase of this is possible without a complete departure from the present type of marine boiler. On the other hand, without a material increase of pressure there is little advantage in quadruple expansion.

Surface condensers

225. Surface condensation was introduced in marine engines by S. Hall in 1831, but was not brought into general use until much later. Previous to this it had been necessary, in order to avoid the accumulation of too dense brine in the boiler, to blow off a portion of the brine at short intervals and replace it by sea water, a process which of course involved much waste of heat. By the use of surface condensers it became possible to use the same portion of water over and over again. The very freedom of the condensed water from dissolved mineral substances was for a time an obstacle to the adoption of surface condensers, for it was found that the boiler, no longer protected by a deposit of scale, became rapidly corroded through the action of acids formed by the decomposition of the lubricating oil. This objection was overcome by introducing a sufficient amount of salt water to allow some scale to form, and the use of surface condensers soon became universal on steamers plying in sea water. The marine condenser consists of a multitude

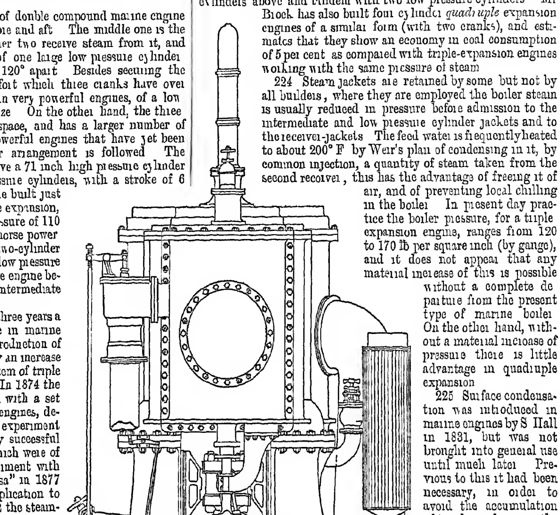

FIG. 135.—End Elevation of Marine Engine.

[1] See description of the engines of the "City of Rome," with three 46 inch and three 86 inch cylinders, with a stroke of 6 feet, working up to 11,890 I. H. P., *Proc. Inst. Mech. Eng.*, 1880.

[2] The rapid progress of the system of triple expansion may be judged from the fact mentioned by Mr W. Parker of Lloyds in a recent paper (*Engineering*, July 30, 1886), that, out of 199 engines then being built for merchant steamers, 128 sets were of the triple expansion type. For war ships also triple engines are being built of sizes up to 13,000 horse power. For a discussion of several important points in the design of triple expansion engines, see a paper by R. Wyllie, *Proc. Inst. Mech. Eng.*, Oct. 1886.

of tubes, generally of brass, about ⅝ of an inch in diameter Through these cold sea water is made to circulate, while the steam is brought into contact with their outside surfaces In some cases, especially in Admiralty practice, cold water circulates outside the tubes and the steam passes inside

Marine engine pumps

226 The ordinary marine engine has four pumps —the air-pump, which is made large enough to serve in case injection instead of surface condensation should at any time be resorted to, the feed pump, the circulating pump, which maintains a current of sea water through the tubes of the condenser, and the bilge pump, which discharges any water accumulated by leakage or otherwise in the bilge of the ship The pumps are so arranged that in the event of a serious leak the circulating pump can also draw its supply from the bilge In most engines, especially those of less recent construction, the four pumps are placed behind the condenser, and are worked by a single crosshead driven by a lever, the other end of which is connected by a short link with one of the cross heads of the engine It is now becoming common to use a small engine, distinct from the main engine, to drive the feed-pump, and to supply circulating water by a centrifugal pump also driven by a separate engine

Relation of coal burnt to power

227 In the improvement of the marine engine two points are noteworthy,—reduction in the rate of consumption of coal per horse-power, and reduction in the weight of the machine (comprising the engine proper and the boilers) per horse-power The second consideration is in some cases of even more moment than the first, especially in war-ships Progress has been made, in both respects, by increase of steam pressure, and, in the second respect especially, by increase of piston speed Fifty years ago the boilers of marine engines made steam at a pressure of about 5 lb per square inch above that of the atmosphere By 1860 compound engines were in use with pressures ranging from 25 to 40 lb In 1872 statistics collected for nineteen ocean steamers showed that the average consumption of coal was then 2 11 lb per H P per hour, the boiler-pressure 45 to 60 lb, and the mean piston speed about 375 feet per minute[1] These were for the most part two cylinder compound engines of the vertical inverted type Nine years later statistics for thirty engines of the same type showed a consumption of 1 83 lb of coal, a mean boiler pressure of 77½ lb, and a mean piston speed of 467 feet per minute[2] In recent triple-expansion engines the pressure is as high as 165 lb, a piston speed of 700 or 800 feet per minute is not uncommon in naval engines, and in some cases it has risen to over 1000 feet per minute[3] The economy in coal consumption brought about by the change from double expansion engines working at (say) 80 lb to triple engines at 160 lb or more is variously estimated at from 18 to 25 per cent Much of this is due simply to the increased range of temperature through which the working substance is carried, but it appears that the actual performance of the triple engine is better than that of the double compound in a ratio greater than that by which its ideal efficiency—as an engine using a wider range of temperature—exceeds that of the other, and this is to be ascribed to the same causes as have been already discussed in speaking of the advantage of the compound over the simple engine Apart from its greater economy of coal, the triple engine owes some of its practical success to the mechanical superiority of three driving cranks over two

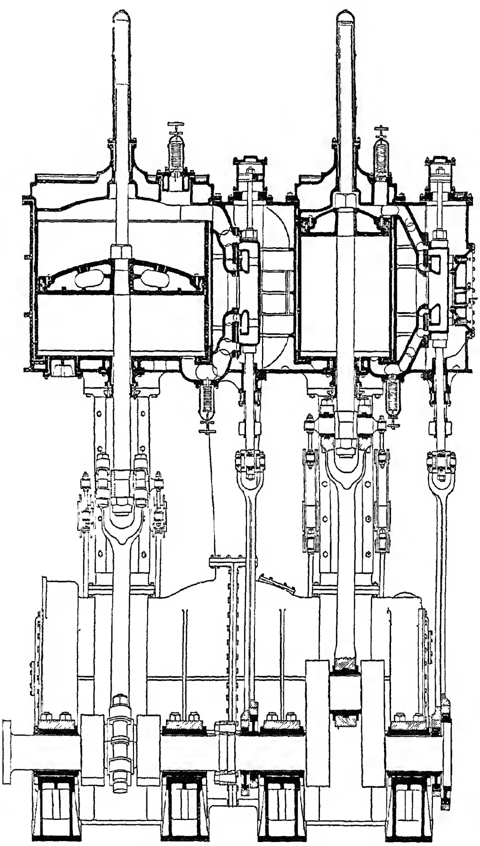

FIG 136 —Longitudinal Section of Marine Engine

Relation of weight to power

228 The relation of weight of machinery to power developed, and the causes which affect this ratio, have recently been discussed by Messrs Marshall and Weighton,[4] from whose paper the following figures are taken Before the introduction of triple expansion and forced draught the weight of engines in the mercantile marine, including the boilers and the water in them, was 480 lb per I H P In the navy this was reduced, chiefly by the use of lighter framing, with the object of minimizing weight, to 360 lb Triple engines of the merchant type, without forced draught, are only slightly lighter than double engines, but in naval practice, where forced draught, greatly increased speed, and the use of steel for frames and working parts have combined to reduce the ratio of weight to power, a marked reduction in weight is apparent A recent set of vertical triple engines, which with natural draught indicate 2200 H P, and with a draught forced by pressure in the stokehole equal to 2 inches of water indicate 4000 H P, weigh under the latter condition (along with the boilers) only 155 lb per I H P In another set, in which the draught is forced by a pressure of 3 inches, and the cylinders are only 15½, 24, and 37 inches in diameter, with a stroke of 16 inches, the indicated horse power is 4200, and the weight of engines and boilers is 136 lb per I H P In these the boilers are of the locomotive type, and the mean piston speed is 1066 feet per minute Even these light weights are surpassed in smaller engines, such as those of torpedo boats In so far as this immense development of power from a small weight of machinery is due to high piston speed, it is secured without loss —indeed with some gain—of thermodynamic efficiency; forced draught, however, without a corresponding extension of the heating

surface, leads to a less efficient expenditure of fuel With a given type of engine there is a certain ratio of expansion which gives a minimum in the ratio of weight to power, when this ratio of expansion is exceeded the engines have to be enlarged to an extent that

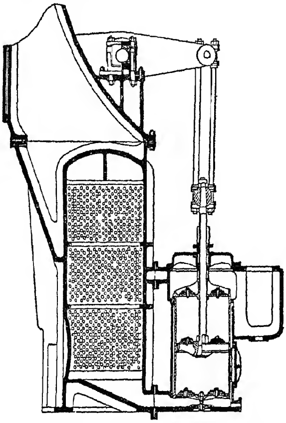

Fig 137—Section through Condenser and Air Pump

more than counterbalances the saving in boiler weight, when a less ratio of expansion is used the boilers have to be enlarged to an extent that more than counterbalances the reduction of weight in the engine proper [1]

XIII Locomotive Engines

Locomotive engines 229 The ordinary locomotive consists of a pair of direct acting horizontal or nearly horizontal engines, fixed in a rigid frame under the front end of a boiler of the type described in § 133, and coupled to the same shaft by cranks at right angles, each with a single slide-valve worked by a link-motion, or by a form of radial gear The engine is non-condensing, except in special cases, and the exhaust steam, delivered at the base of the funnel through a blast-pipe, serves to produce a draught of air through the furnace In some instances a portion of the exhaust steam, amounting to about one-fifth of the whole, is diverted to heat the feed-water In tank engines the feed-water is carried in tanks on the engine itself, in other engines it is carried behind in a tender

Driving-wheels 230 On the shaft are a pair of driving-wheels, whose frictional adhesion to the rails furnishes the necessary tractive force In some engines a single pair of driving-wheels are used, in many more a greater tractive force is secured by having two equal driving wheels on each side, connected by a coupling rod between pins on the outside of the wheels In goods engines a still greater proportion of the whole weight is utilized to give tractive force by coupling three and even four wheels on each side These arrangements are distinguished by the terms "four-coupled," "six-coupled," and "eight coupled" applied to the engines In *inside-cylinder* engines the cylinders are placed side by side within the frame of the engine, and their connecting-rods work on cranks in the driving shaft Inside and outside cylinder engines In *outside cylinder* engines the cylinders are spread apart far enough to lie outside the frame of the engine, and to work on crank-pins on the outsides of the driving wheels This dispenses with the cranked axle, which is the weakest part of a locomotive engine Owing to the frequent alternation of strain to which it is subject, a locomotive crank axle is peculiarly liable to rupture, and has to be removed after a certain amount of use

In some locomotives the leading wheels are coupled to driving wheels behind them, but it is now generally preferred to have under the front of the engine two or four smaller wheels which do not form part of the driving system These are carried in a *bogie*, that is, a small truck upon which the front end of the boiler rests by a swivel-pin or plate which allows the bogie to turn, so as to adapt itself to curves in the line, and thus obviate the grinding of tyres and danger of derailment which would be caused by using a long rigid wheel-base The bogie appears to have been of English origin,[2] it was brought into general use in America, and is now common in English as well as in American practice Instead of a four-wheeled bogie, a single pair of leading wheels are also used, carried by a Bissel *pony* truck, which has a swing bolster pivoted by a radius bar about a point some distance behind the axis of the wheels This has the advantage of combining lateral with radial movement of the wheels, both being required if the wheel base is to be properly accommodated to the curve Another method of getting lateral and radial freedom is the plan used by Mr Webb of carrying the leading axle in a box curved to the arc of a circle, and free to slide laterally for a short distance, under the control of springs, in curved guides[3] Leading wheels Bogie Pony truck Radial axle box

Valves 231 In inside cylinder engines the slide-valves are frequently placed back to back in a single valve-chest between the cylinders The width of the engine within the frame leaves little room for them there, and they are reduced to the flattest possible form, in some cases with split ports, half above and half below a partition in a central horizontal plane In some of Mr Stroudley's engines the valves are below the cylinders, with faces sloping down towards the front, while the cylinders themselves slope slightly up In many engines the valves work on horizontal planes above the cylinders, this position is specially suitable when Joy's or some other form of radial gear is used instead of the link-motion Radial valve gears have the advantage, which is of considerable moment in inside-cylinder engines, that the part of the shafts' length which would otherwise be needed for eccentrics is available to increase the width of main bearings and crank-pins, and to strengthen the crank-cheeks Walshaert's gear is very extensively used on Continental locomotives, and Joy's has now been applied to a large number of British engines

232 In a powerful locomotive of the ordinary type the cylinders are 17 to 19 inches in diameter, with a stroke of about 26 inches The steam pressure is 130 to 175 lb The horse-power ranges up to about 700 A passenger engine for express service has driving wheels from 7 to 8 feet in diameter, and weighs, without the tender, about 40 tons Of this nearly 15 tons is borne by each driving axle[4]

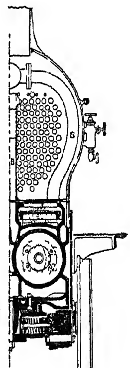

Fig 138—Inside Cylinder Locomotive

Inside-cylinder engine. Fig 138 shows a half section through the smoke-box and one cylinder of an inside-cylinder engine (of the Midland Railway), and illustrates how in an engine of

[4] For account of many details in recent English practice in locomotive building, reference should be made to a valuable paper by Mr Stroudley, and a discussion upon it (*Min Proc Inst C E*, lxxxi)

this type the cylinders are situated with regard to the frame, which consists of a single pair of steel plates, extending from end to end and united by other transverse plates, one of which, called the motion-plate, gives support to the guide-bars, and another holds the draw-bar. Another form of frame is built up of two longitudinal plates on each side. In the engine illustrated the valves are above the cylinders, and are worked by Joy's gear. A bogie truck appears in section below the engine. S is the steam-pipe, and B the blast-pipe, which is tapered in the fore-and-aft plane.

Outside cylinder engine.

233. The outside-cylinder type is adopted by several British makers; in America it is universal. There the cylinders are in castings which are bolted together to form a saddle on which the bottom of the smoke box sits. The slide-valves are on the tops of the cylinders, and are worked through rocking levers from an ordinary link-motion. Other features by which American practice is distinguished are the use of bars instead of plates for the frames, of cast-iron wheels with chilled rims instead of wrought-iron wheels with steel rims shrunk or forced on, and steel fire-boxes and wrought-iron tubes instead of copper fire-boxes and brass tubes. Fig. 139, which is a half section through one cylinder of an American locomotive, by the Balwin Company of Philadelphia, shows the position of the cylinders and valves.

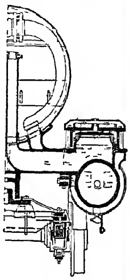

FIG. 139.—American Outside Cylinder Locomotive.

234. Locomotive engines have been compounded in several ways. In 1876 M. A. Mallet[1] introduced, on the Bayonne and Biarritz Railway, a type of compound locomotive in which one small high-pressure cylinder and one large low-pressure cylinder were used in place of the two equal cylinders of a common locomotive. Outside cylinders were used in the first instance, but Mallet's system is also applied to inside-cylinder engines. The pipe from the high to the low-pressure cylinder takes a winding course through the smoke-box; this gives a sufficient volume of intermediate receiver, and also dries the steam before it enters the large cylinder. A reducing valve is provided through which steam of a pressure lower than that of the boiler can be admitted direct to the low-pressure cylinder to facilitate starting. The reversing gear is arranged to act on both cylinders by one movement, and also to permit a separate adjustment of the cut-off in each. Engines on Mallet's system have been successfully used on other Continental railways and in India, in some instances by conversion from the non-compound form.[2] His plan has the advantage of permitting this (in certain cases), and of requiring scarcely any more working parts than are needed in a common locomotive; but it gives an unsymmetrical engine. He has also proposed an engine with four cylinders,—one high-pressure cylinder tandem with one low-pressure cylinder on each side. Another symmetrical form has been used, in which a pair of outside high-pressure cylinders are compounded with a pair of inside low pressure cylinders.

Compound locomotives.

Webb's system.

235. The most important experiment yet made in the compounding of locomotives is that which Mr F. W. Webb, of the London and North-Western Railway, has been conducting on a large scale since 1881.[3] In Mr Webb's system three cylinders are used. Two equal high-pressure

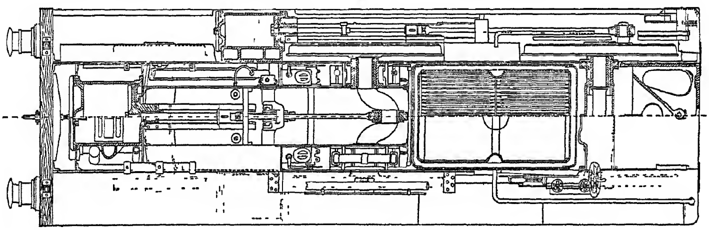

FIG. 140.—Webb's Compound Locomotive.

cylinders are fixed outside the frames, and drive the rear driving axle by crank-pins at right angles to one another. A single low-pressure cylinder of very large size is set beneath the smoke-box, and drives a crank in the middle of the forward driving axle. The driving axles are not coupled, and the phase relation of the low-pressure to the high-pressure stroke is liable to alter through unequal slip on the part of the wheels. This, however, is of no material consequence, on account of the large size of the intermediate receiver and the uniformity with which the two high-pressure cylinders deliver steam to it. The receiver is formed, as in M. Mallet's arrangement, by leading long connecting pipes through the smoke-box. All three slide-valves are worked by Joy's gear. Those of the low-pressure cylinders are placed below the cylinders (an arrangement which has the advantage of letting the valve fall away from the port-face when the engine is running down hill with the steam-valve closed), the valve of the large cylinder is above it. The arrangement is completely symmetrical; it has the important mechanical advantage of dispensing with coupling rods, while retaining the greater tractive power of four drivers; only one axle is cranked, and that with a single crank in the centre, which leaves ample room for long bearings. A plan of Mr Webb's engine, half in section, is given in fig. 140. The results of Mr Webb's experiments have been, in his judgment, so satisfactory that for express passenger service he is now building engines only of the compound type. In some recent examples the small cylinders are 14 inches, and the large cylinder 30 inches in diameter, with a stroke of 24 inches, and the boiler pressure is 175 lb. Engines of the same type are also being introduced in India, South America, and the continent of Europe.

236. Experiments on the saving of fuel by compounding locomotives point to an economy of from 10 to 20 per cent. It may be expected, for reasons which have been discussed above, that a compound engine, even when working at the high speed of a locomotive, will have a somewhat higher efficiency than a non-compound engine

But, apart from this, an important merit of the compound system is that, while it absolutely prevents the grade of expansion from being reduced below a certain minimum, depending on the ratio of cylinder volumes, it also permits a comparatively high degree of expansion, which in an ordinary locomotive would involve the use of specially large cylinders and a separate cut-off valve Experiments on the steam-jacketing of locomotive cylinders have not hitherto been attended by success

Tramway locomotives

237 *Tramway locomotives* for the most part resemble railway locomotives in the general features of their design The boiler is of the usual locomotive type A pair of cylinders in front, either inside or outside the frames, are connected directly to the hindmost of two coupled driving axles Owing to the smallness of the driving-wheels, the axles lie near the road, and the cylinders are set sloping at a considerable angle upwards to keep them clear of dirt To prevent the discharge of steam into the atmosphere, the exhaust steam is often led into an atmospheric condenser, consisting of a large number of pipes set on the top of the engine, and exposed to free contact with the air In some instances the common locomotive type is widely departed from a mixed vertical and horizontal boiler is used, and the engine is connected to the driving axle by worm-wheel or other gear, or by a rocking lever between the connecting-rod and the crank [1]

Fireless locomotive

238 In the "fireless" tramway locomotive of M Léon Francq, a reservoir which takes the place of an ordinary boiler is charged at the beginning of the journey with water heated under pressure by injecting steam from stationary boilers at a pressure of 15 atmospheres The thermal capacity of the water is sufficient—without further addition of heat—to supply steam to the engine during the journey, at a pressure which gradually falls off [2] The system has not come into general use

239 Several forms of tramway engine have been devised in which the motive power is supplied by compressed air [3] In the Mekarski system the compressed air, on its way from the reservoir to the cylinders, passes through a vessel containing hot water and steam under pressure (charged, as in Francq's system, by injecting steam at a station) In this way the air is heated, and may then expand in the cylinder without having its temperature lowered to an objectionable degree

Traction engines

240 Steam *road-locomotives* or traction-engines have usually a boiler of the locomotive type, with a cylinder or compound pair of cylinders, generally on the top, driving a shaft from which motion is taken by a gearing chain or spur-wheels to a single driving axle at the fire-box end The engine is steered by means of a leading axle, whose direction is controlled by a hand-wheel and chain-gear To facilitate rapid turning the driving-wheels are connected to their axle by a differential or compensating gear which allows them to revolve at different speeds This is a set of four bevel-wheels like White's dynamometer coupling the outside bevel-wheels are attached to the driving-wheels, the intermediate ones, which gear with these, turn in bearings in a revolving wheel driven by the engine So long as both driving-wheels are equally resisted both are driven at the same speed, but if one is retarded (as the inner wheel is in turning a curve) it acts to some extent as a fulcrum to the bevel gear, and the outer wheel takes a greater share of the motion An important feature in traction engines is the elasticity of the driving-wheels Many devices have been employed, partly to give the wheels an extended tread, or arc of contact with the ground, and partly to avoid shocks in passing over rough ground Both objects are accomplished by Mr R W Thomson's plan of surrounding each wheel with a thick tyre of india rubber, protected on the outside by an armour of small plates In most modern traction-engines the rim is itself rigid, but is connected to the nave through a system of springs which allow it to take up an eccentric position, and the tyres have skew bars on the surface to increase their adhesion to the road

XIV AIR AND GAS ENGINES

Air and gas engines

241 Under this head we may include all heat-engines in which the working substance is air, or the gaseous products of the combustion of fuel and air, whether the fuel be itself solid, liquid, or gaseous When air alone forms the working substance, it receives heat from an external furnace by conduction through the walls of a containing vessel, as the working substance in the steam-engine takes in heat through the shell of the boiler An engine supplied with heat in this way may be called an *external-combustion* engine, to distinguish it from a very important class of engines in which the combustion which supplies heat occurs within a closed chamber containing the working substance The ordinary coal-gas explosive engine is the most common type of *internal-combustion* engine

242 Compared with an engine using saturated steam, air and gas engines have the important advantage that the temperature and the pressure of the working substance are independent of one another Hence it becomes possible to use an upper limit of temperature greatly higher than in the ordinary steam-engine, and if the lower limit is not correspondingly raised an increase of thermodynamic efficiency results It is true that the same advantage might be obtained in the case of steam, by excessive superheating, but this would mean substantially the conversion of the engine into the type we are now considering, the working substance being then steam gas

243 A simple, thermodynamically perfect form of external combustion air-engine would be one following Carnot's cycle (§ 40), in which heat is received while the air is at the highest temperature τ_1, the air meanwhile expanding isothermally After this the supply of heat is stopped, and the air is allowed to expand adiabatically until its temperature falls to the lower extreme τ_2 At this it is compressed isothermally, giving out heat and finally the cycle is completed by adiabatic compression, which restores the initial high temperature τ_1

Stirling's air engine

244 In place of adiabatic expansion as a means of changing the temperature from τ_1 to τ_2 we may follow Stirling's plan (§ 54) of storing the heat in a regenerator, from which it will afterwards be taken up and so produce the elevation of temperature from τ_2 to τ_1 which in the above cycle was performed by adiabatic compression

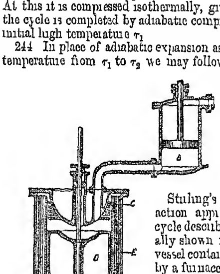

FIG. 141.—Stirling's Air Engine

Stirling's air engine, in which the action approximated to the perfect cycle described in § 54, is diagrammatically shown in fig 141 A is a closed vessel containing air, externally heated by a furnace beneath it A pipe from the top of A leads to the working cylinder B At the top of A is a refrigerator C, consisting of pipes through which cold water circulates In A there is a displacer plunger D, which is driven by the engine, when this is raised the air in A is heated, whereas when D is lowered the air in A is brought into contact with the refrigerator and cooled On its way from the bottom to the top of A, or *vice versa*, the air must pass through an annular lining of wire-gauze E This is the regenerator At the beginning of the cycle D is up The air is then receiving heat at τ_1, and is expanding isothermally, this is the first stage in § 54 Then the plunger D descends The air is driven through the regenerator, where it deposits heat, and its temperature on emerging at the top is τ_2 Next, the working-

[1] See *Min Proc Inst CE*, vol xxix, 1884, also *Proc Inst Mech Eng*, 1880
[2] *Proc Inst Mech Eng*, 1879
[3] *Proc Inst Mech Eng*, 1878, 1881

piston makes its down stroke (in the actual engine the working cylinder was double acting, another heating vessel, precisely like A, being connected with the cylinder B above the piston), this compresses the air isothermally the heat produced by compression being taken up by C Finally the plunger is raised, and the working air again passes through the regenerator, taking up the heat it left there, and rising to τ_1 The theoretical indicator diagram has been given in fig 13

245 The actual forms in which Stirling's engine was used are described in two patents by R & J Stirling (1827 and 1840[1]) An important feature in them was that the air was compressed (by means of a pump) to a pressure greatly above that of the atmosphere Stirling's cycle is theoretically perfect whatever the density of the working air, and compression did not in his case increase what may be called the theoretical thermodynamic efficiency It did, however, very greatly increase the mechanical efficiency, and also, what is of special importance, it increased the amount of power yielded by an engine of given size To see this it is sufficient to consider that with compressed air a greater amount of heat was dealt with in each stroke of the engine, and therefore a greater amount of work was produced Practically it also increased the thermodynamic efficiency by reducing the ratio of the heat wasted by external conduction and radiation to the whole heat

A double acting Stirling engine of 50 I H P, used in 1843 at the Dundee foundry, appears to have realized an efficiency of 0 3, and, notwithstanding very inadequate means of heating the air, consumed only 1 7 lb of coal per I H P per hour [2] This engine remained at work for three years, but was finally abandoned on account of the failure of the heating vessels In some forms of Stirling's engine the regenerator was a separate vessel, in others the plunger D was itself constructed to serve as regenerator by filling it with wire gauze and leaving holes at top and bottom for the passage of the air through it

Ericsson's air-engine 246 Another mode of using the regenerator was introduced in America by Ericsson, in an engine which also failed, partly because the heating surfaces became burnt, and partly because their area was insufficient In Ericsson's engine the temperature of the working substance is changed (by passing through the regenerator) while the pressure remains constant Cold air is compressed by a pump into a receiver, from which it passes through a regenerator into the working cylinder In so passing it absorbs heat from the regenerator and expands The air in the cylinder is then further expanded by taking in heat from a furnace under the cylinder The cycle is completed by the discharge of the air through the regenerator The indicator diagram approximates to a form bounded by two isothermals and two lines of constant pressure [3]

247 Externally-heated air engines are now employed only for very small powers—from a fraction of 1 H P up to about 3 H P Powerful engines of this type are impracticable on account of their relatively enormous bulk Those that are now manufactured resemble the original Stirling engine very closely in the main features of their action, and comprise essentially the same organs [4]

Internal combustion engines 248 *Internal-combustion* engines form a far more important class of motors The earliest example of this class appears to have been the hot-air engine of Sir George Cayley,[5] of which Wenham's[6] and Buckett's[7] engines are recent forms In these engines coal or coke is burnt under pressure in a closed chamber, to which the fuel is fed through a species of air-lock Air for combustion is supplied by a compressing pump, and the engine is governed by means of a distributing valve which supplies a greater or less proportion of the air below the fire as the engine runs slow or fast The products of combustion, whose volume is increased by their rise in temperature, pass into a working cylinder, raising the piston When a certain fraction of the stroke is over the supply of hot gas is stopped, and the gases in the cylinder expand, doing more work and becoming reduced in temperature During the return stroke they are discharged into the atmosphere, and the pump takes in a fresh supply of air Fig 142 is a diagram section of the Buckett engine A is the working piston, the form of which is such as to protect the tight sliding surface (at the top) from contact with the hot gases, B is the compressing pump, C the valve by which the governor regulates the rate at which fuel is consumed, and D the air-lock through which fuel is supplied

249 In engines of this class the degree to which the action is thermodynamically efficient depends very largely on the amount of cooling the gases undergo by adiabatic or nearly adiabatic expansion under the working piston Without a large ratio of expansion the thermodynamic advantage of a high initial temperature is lost, but, as the gases have to be discharged at atmospheric pressure, a large ratio of expansion is possible only when there is much initial compression Compression is therefore an

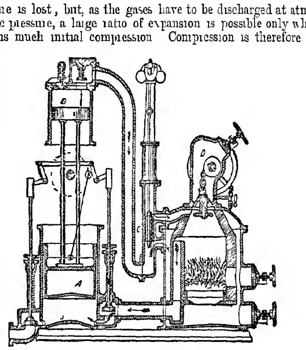

Fig 142 —Buckett Engine

essential condition, without which a heat engine of this type can not be made efficient It is also, as has already been pointed out, essential in all air engines to the development of a fair amount of power by an engine of moderate bulk

250 Internal combustion engines using solid fuel have hitherto been little used, and that only for small powers Several small engines employ liquid fuel (namely, petroleum) injected in a state of spray, or even vaporized before entering the combustion chamber In some forms, of which the Brayton petroleum engine is a type, combustion occurs as the fuel is injected, in others the action approaches closely that of *gas engines*, that is to say, of engines in which fuel (generally coal gas) is supplied in a perfectly gaseous state, and is burnt in a more or less explosive manner These last are the only heat engines that have as yet entered into serious competition with steam engines Petroleum engines Gas engines

251 The earliest gas-engine to be brought into practical use was that of Lenoir (1860) During the first part of the stroke air and gas, in proportions suitable for combustion, were drawn into the cylinder At about half stroke the inlet valve closed, and the mixture was immediately exploded by an electric spark The heated products of combustion then did work on the piston during the remainder of the forward stroke, and were expelled during the back stroke The engine was double acting, and the cylinder was prevented from becoming excessively heated by a casing through which water was kept circulating The water-jacket has been retained in nearly all later gas engines Lenoir

An indicator diagram from a Lenoir engine is shown in fig 143 [8] After explosion the line falls, partly from expansion, and partly from the cooling action of the cylinder walls, on the other hand, its level is to some extent maintained by the phenomenon of after burning, which will be discussed later In this engine, chiefly because there was no compression, the heat removed by the water jacket bore an exceedingly large proportion to the whole heat, and the efficiency was comparatively low, about 95 cubic feet of gas were used per horse power per hour Hugon's engine, introduced five years later, was a non-compressive engine very similar to Lenoir's A novel feature in it was the injection of a jet of cold water to keep the cylinder from becoming too hot These engines are now obsolete, the type they belonged to, in which the mixture is not compressed before explosion, is now represented by one small engine—Bischoff's—the mechanical simplicity of which atones for its comparatively wasteful action in certain cases where but little power is required Hugon Bischoff.

Fig 143 —Lenoir Engine Diagram

252 In 1866 Otto and Langen introduced a curious engine,[9] which, as to economy of gas, was distinctly superior to its predecessors Like them it did not use compression The explosion occurred early in the stroke, in a vertical cylinder, under a piston which was free to rise without doing work on the engine shaft The piston rose with great velocity, so that the expansion was much more nearly adiabatic than in earlier engines Then after the piston had reached the top of its range the gases cooled, and their pressure fell below that of the atmosphere, the piston consequently Otto and Langen

came down, this time in gear with the shaft, and doing work. The burnt gases were discharged during the last part of the down stroke. A friction-coupling allowed the piston to be automatically thrown out of gear when rising, and into gear when descending. This "atmospheric" gas engine used about 40 cubic feet of gas per horse-power per hour, and came into somewhat extensive use in spite of its noisy and spasmodic action. After a few years it was displaced by a greatly improved type, in which the direct action of Lenoir's engine was restored, but the gases were compressed before ignition.

Otto's engine. 253. Dr Otto's "silent" engine, introduced in 1876, was the first successful motor of the modern type. It is a single-acting engine, generally horizontal in form, and the explosive mixture is compressed in the working cylinder itself. This is done by making the cycle of the action extend through two revolutions of the engine. During the first forward stroke gas and air are drawn in by the piston. During the first back-stroke the mixture is compressed into a large clearance space at the end of the cylinder. The mixture is then ignited, and the second forward stroke (which is the only working stroke in the cycle) is performed under the pressure of the heated products of combustion. During the second back-stroke the products are discharged, with the exception of so much as remains in the clearance space, which serves to dilute the explosive mixture in the next cycle. The principal parts of Otto's engine (as made by Messrs Crossley) are shown in the diagram section, fig. 144. The cylinder is kept

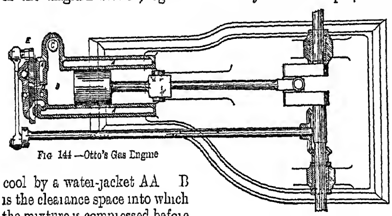

Fig. 144.—Otto's Gas Engine.

cool by a water-jacket AA. B is the clearance space into which the mixture is compressed before explosion. Its volume is usually about two-thirds of the stroke, or 40 per cent. of the whole volume to which the gases afterwards expand. C is the exhaust-valve, which is opened during the second back-stroke of each cycle. Gas and air are admitted at D, through a slide-valve E, which reciprocates once in each complete cycle of two revolutions. This slide-valve is shown to a larger scale in fig. 145, in the position it occupies while gas is entering from g and air from a. To ignite the mixture a gas-jet is kept burning at c. In the slide-valve there is an igniting port d, which is supplied with gas

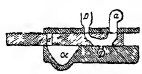

Fig. 145.

from a groove in the cover. As the slide moves towards the right, the igniting port d carries a flame from c to D. Just before reaching D a little of the compressed mixture from the cylinder enters the igniting port by a small opening which does not appear in the figure, and by the time D is reached the contents of d are so much raised in pressure by their own combustion that a tongue of flame shoots into the cylinder, firing the mixture there. The speed is regulated by a centrifugal governor, which cuts off the supply of gas when the speed exceeds a certain limit. In some small Otto engines of recent construction the inertia of a reciprocating piece is used instead of the inertia of revolving pieces to effect the same end.

Clerk's engine. 254. In Mr Clerk's engine the cycle of operations is essentially the same as in Otto's, but a charging cylinder is introduced, with the effect of allowing an explosion to take place in the working cylinder once in every revolution. As in Otto's, there is a large clearance space behind the piston, and the mixture is compressed into this space by the backward movement of the working piston. The peculiarity of the engine lies in the manner in which the charge is introduced. As the piston advances after an explosion it uncovers exhaust ports in the sides of the cylinder, close to the end of its forward stroke. While it is passing the dead-point there the plunger of the charging cylinder (which has meanwhile taken in a mixture of gas and air) delivers this mixture into the cylinder, driving the products of the previous combustion out of the cylinder through the exhaust ports. The charging cylinder is so arranged that the first part of the charge consists almost wholly of air, and this is followed by the explosive mixture of gas and air. The working piston then returns, closing the exhaust ports and compressing the mixture, which is ignited after compression by means of a slide-valve similar to Otto's. In Otto's engine the explosive mixture is diluted, and the sharpness of the explosion thereby reduced, by the residue of burnt products which fill the clearance space at the end of the discharge stroke. In Clerk's engine the mixture is diluted by an excess of air. It does not appear that this difference has any material effect on the action.

255. Over 20,000 Otto engines are now in use, of power ranging up to about 40 H.P. Besides the engines which have been named, others are manufactured in which the operations are essentially of the same kind, though in some cases the mechanical details are widely varied. In one of these, Mr Atkinson's ingenious "differential" engine, the working chamber consists of the space between two pistons working in one cylinder. During exhaust the pistons come close together; they recede from each other to take in a fresh charge; they approach for compression; and finally they recede again very rapidly and farther than before, after ignition of the mixture, thus giving a comparatively large ratio of expansion. At the same time, by moving bodily along through the cylinder, the pistons uncover admission and exhaust ports and an ignition-tube, which is kept permanently incandescent.

256. If the explosion of a gaseous mixture were practically instantaneous, producing at once all the heat due to the chemical reaction, and if the expansion and compression were adiabatic, the theoretical indicator diagram of an engine of the Otto type would have the form shown in fig. 146. OA represents the volume of clearance; AB is the admission, at atmospheric pressure; BC is the compression (which is assumed to be adiabatic); CD is the rise of pressure caused by explosion; DE is adiabatic expansion during the working stroke; and EBA is the exhaust. The height of the point D above C may be calculated when we Theoretical indicator diagram of Otto engine.

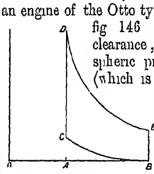

Fig. 146.

know the temperature at C (an element of considerable uncertainty in practice), the specific heat (at constant volume) of the burnt mixture, the amount of heat evolved by explosion, and the change of specific density due to the change of chemical constitution which explosion brings about. With the proportion of coal-gas and air ordinarily employed this last consideration may generally be neglected, as the volume of the products would differ by less than 2 per cent. from the volume of the mixture before explosion if both were reduced to the same pressure and temperature.

257. The rise of pressure observed in the indicator

Actual diagram of Otto engine

diagrams of gas engines is found to be in all cases much less than the calculated rise of pressure which would be caused by a strictly instantaneous explosion. An actual diagram from an Otto engine working in its normal manner is given in fig. 147, where the reference letters distinguish the parts of a complete cycle, as in fig. 146. It shows a rapid rise of pressure on explosion, so rapid that the volume has not very materially altered when the maximum of pressure is reached, and the specific heat at constant volume may therefore be used without serious error in calculating the amount of heat which this rise accounts for. When this calculation is made,[1] it turns out that only about 60 or 70 per cent. of the potential heat of combustion in the mixture is required to produce the rise of temperature corresponding to the point of greatest pressure. The remainder continues to be slowly evolved during the subsequent expansion of the hot gases. The process of combustion—a term evidently more appropriate than explosion—is essentially gradual; when ignition takes place it begins rapidly, but it continues to go on at a diminishing rate throughout the stroke. That part which takes place after the maximum pressure is passed is the phenomenon of after-burning to which allusion has been made above.

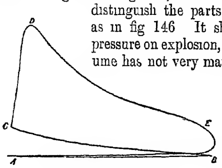

FIG. 147.—Otto Engine Diagram.

After-burning

258. The existence of "after-burning" is proved not only by the fact that the maximum pressure after ignition is much less than it would be if combustion were then complete, but also by the form which the curve of subsequent expansion takes. During expansion the gases are losing much heat by conduction through the cylinder walls. The water-jacket absorbs rather more than half of the whole heat developed in the engine,[2] and the greater part of this is of course taken up from the gases during the working stroke. Notwithstanding this loss, the curve of expansion does not fall much below the adiabatic curve; in some cases it even lies higher than the adiabatic curve. This shows that the loss to the sides of the cylinder is being made up by continued development of heat within the gas. The process of combustion is especially protracted when the explosive mixture is weak in gas; the point of maximum pressure then comes late in the stroke, and it is probable that the products which are discharged in the exhaust contain some incompletely-burnt fuel. Fig. 148 is the indicator diagram of an Otto engine supplied with a mixture containing an exceptionally large proportion of air: it exhibits well the very gradual character of the explosion in such a case.

FIG. 148.—Otto Engine Diagram with weak explosive mixture.

Clerk's experiments

259. Much light has been thrown on this subject by the experiments of Mr Clerk, who has exploded mixtures of gas and air, and also mixtures of hydrogen and air, in a closed vessel furnished with an apparatus for recording the time rate of variation of pressure. In these experiments the pressure fell after the explosion only on account of the cooling action of the containing walls. The temperature before ignition being known, it became possible to calculate from the diagrams of pressure the highest temperature reached during combustion (on the assumption that the specific heat of the gases remained unchanged at high temperatures), and to compare this with the temperature which would have been produced had combustion been at once complete. Mixtures of gas and air were exploded, the proportion of gas varying from $\frac{1}{15}$ to $\frac{1}{5}$, and the highest temperature produced was generally a little more than half that which would have been reached by instantaneous combustion of the mixture. With the best proportion of coal gas to air (1 to 6 or 7) the greatest pressure and hottest state was found one twentieth of a second after ignition, and the temperature was then 1800° C.,—instead of 3800°, which would have been the value had all the heat been at once evolved. With the weakest mixtures about half a second was taken to reach a maximum of temperature, and its value was 800° C., instead of 1800° C. In this case, however, the degree of completeness of the combustion is not fairly shown by a comparison of these temperatures, since much cooling occurred during the relatively long interval that preceded the instant of greatest pressure.

Dissociation

260. To explain the phenomenon of after-burning or delayed combustion, it has been supposed that the high temperature to which the gases are raised in the first stages of the explosion prevents union from being completed,—just as high temperature would dissociate the burnt gases were they already in chemical union,—until the fall of temperature by expansion and by the cooling action of the cylinder walls allows the process of union to go on. The maximum temperature attained in the gas-engine is high enough to cause a perceptible amount of dissociation of the burnt products; it may therefore be admitted that this explanation of delayed combustion is to some extent true. On the other hand, the phenomenon is most noticeable with mixtures weak in gas, in which the maximum temperature reached is low, and the dissociation effect is correspondingly small. It appears, therefore, that dissociation is not the main cause of the action; apart from it the process of combustion of a gaseous mixture is gradual, beginning fast and going on at a continuously-diminishing rate as the combustible mixture becomes more and more diluted by the portions already burnt. If the mixture is much diluted to begin with, the process is comparatively slow from the first.

Stratification

261. Much stress has been laid by some makers of gas-engines on the desirability of having a stratified mixture of gases in the cylinder, with a part rich in gas near the ignition port and a greater proportion of residual product or air near the piston. It has even been supposed that stratification of the gases is the cause of their gradual combustion. Mr Clerk's experiments are conclusive against this; the mixtures he used, which gave in some cases very gradual explosions, were allowed to stand long enough to become sensibly homogeneous. In dealing with weak mixtures it is no doubt of advantage to have a small quantity of richer fluid close to the igniting port to start the ignition of the rest,—but beyond this stratification has probably little or no value. And it may be questioned whether, in the ordinary working of a gas-engine, any general stratification can occur, when account is taken of the commotion which the air and gas cause as they rush into the cylinder at a speed exceeding that of an express train.

Efficiency of gas-engines

262. A compression gas-engine of the Otto type burns from 20 to 25 cubic feet of coal-gas per hour per indicated horse-power. Good coal-gas has a heating power equivalent to about 500,000 foot-pounds per cubic foot, and hence, with a consumption of 20 cubic feet the efficiency which the engine realizes is nearly 0.2. The efficiency of a large steam-engine is about 0.14, and in steam-engines that are small enough to be fairly compared with actual gas-engines the efficiency is not more than 0.1. The superiority of gas engines over steam-engines, from the

[1] See two important papers by Mr Dugald Clerk, "On the Theory of the Gas Engine," and "On the Explosion of Homogeneous Gaseous Mixtures," *Min. Proc. Inst. C.E.*, 1882 and 1886. Reference should also be made, on the subject of gas-engines generally, to Mr Clerk's book, *The Gas-Engine*, 1886.

[2] Clerk, *loc. cit.* Also, Brooks and Steward, *Van Nostrand's Eng. Mag.*, 1883; Ayrton and Perry, *Phil. Mag.*, July 1884; Slaby, Report quoted in F. Jenkin's *Lecture*, Inst. C.E., 1884.

thermodynamic point of view, is well shown by comparing their consumption of fuel. In the steam engine we find in good engines of large size a consumption of 2 lb or $1\frac{3}{4}$ lb of coal per I.H.P. per hour, and by triple expansion this is reduced in large marine engines to about $1\frac{1}{3}$ lb. On the other hand, in small-power engines the consumption is at least $2\frac{1}{2}$ lb, and is generally 3 lb or more. When Mr Dowson's cheap gas,[1] which is produced by passing a mixture of superheated steam and air through red-hot anthracite, is used to drive an Otto engine, the consumption of coal has been found to be only 1.1 lb per I.H.P. per hour, or less than half the amount used by a steam-engine of similar size. What gives this comparison additional interest is the fact that the gas-producer for a 40 or 50 H.P. engine need not take up more space than the boiler of a steam-engine of the same power.

263. In another sense the gas-engine is much less perfect than the steam-engine. The actual efficiency of the latter is about half the ideal efficiency which a perfect engine would show when working through the same range of temperature. In the gas-engine the actual is less than one-fourth of the ideal efficiency. Taking the highest temperature as 1900° C.—a value reached in some of Mr Clerk's experiments—and the lowest temperature as 15° C., the efficiency of a perfect engine would be 0.87, while that of the actual engine is 0.2. This only means that the gas engine has all the greater margin for future improvement.

264. At present the main causes of waste in gas-engines are the action of the sides of the cylinder and the water-jacket, and the high temperature of the exhaust gases. The water-jacket absorbs about half the whole heat, only to keep the cylinder cool enough to permit of lubrication. The waste gases are discharged at a temperature of about 420° C., and so carry away a large amount of heat which might in part be saved by having a greater ratio of expansion, or by the use of a regenerator. Another source of thermodynamic imperfection is the after-burning, which gives heat to the working substance at a temperature lower than the maximum.

In an engine constructed by the late Sir William Siemens it was attempted to do away with or reduce the two main causes of loss—(1) by using a separate combustion-chamber, distinct from the cylinder in which the piston worked, and (2) by passing the exhaust gases through a regenerator, which afterwards gave up heat to the incoming air and gas.[2] The late Prof. Fleeming Jenkin endeavoured to attain the same ends by adapting the Stirling type of engine to internal combustion, a mixture of gas and air being exploded under a displacer like that of fig. 141. Practical difficulties have hitherto prevented regenerative internal-combustion engines from coming into use, but it can scarcely be doubted that their development is only a question of time. With regard to the probable future of heat-engines, it is important to notice that the internal-combustion engine using gaseous fuel, though already much more efficient than the steam-engine, is crude and full of defects which further invention ought to remove, while the steam-engine has been improved so far that little increase in its efficiency can be expected, and more than a little is impossible. (J. A. E.)

STEAM HAMMER See HAMMER

STEARINE, in commerce, designates a solid mixture of fatty acids (chiefly palmitic and stearic) which is being produced industrially from animal fats and used largely for the making of candles In chemistry it is a generic term for the three "esters" derivable from glycerin, $C_3H_5(OH)_3$, by the replacement of one or more of the three (OH)'s by the residue $C_{18}H_{35}O_2$, which, in stearic acid, is combined with "H" Of these tri-stearine, $C_3H_5(C_{18}H_{35}O_2)_3$, is the most important, it occurs in animal fats only, largely in tallow It crystallizes from ether in white pearly nodules, insoluble in cold but easily soluble in boiling alcohol It can be distilled undecomposed *in vacuo* On gradual exposure to higher temperatures it fuses at 55° C, it then resolidifies, and then fuses again (permanently) at 71° 5 (Heintz) The specific gravity of the liquid is 0 9245 at 65° 5 C (Duffy)

STEEL See IRON

STEELE, SIR RICHARD (1672–1729), one of the most active and prominent men of letters in the reign of Queen Anne, inseparably associated in the history of literature with his personal friend Addison He cannot be said to have lost in reputation by the partnership, because he was far inferior to Addison in purely literary gift, and it is Addison's literary genius that has floated their joint work above merely journalistic celebrity, but the advantage was not all on Steele's side, inasmuch as his more brilliant coadjutor has usurped not a little of the merit rightly due to him Steele's often-quoted generous acknowledgment of Addison's services in *The Tatler* has proved true in a somewhat different sense from that intended by the writer —"I fared like a distressed prince, who calls in a powerful neighbour to his aid, I was undone by my auxiliary, when I had once called him in I could not subsist without dependence on him" The truth is that in this happy alliance the one was the complement of the other, and the balance of mutual advantage was much more nearly even than Steele claimed or posterity has generally allowed

The famous literary pair were born in the same year, 1672,—Steele in Dublin, the senior by less than two months Steele's father, who is said to have been a lawyer, died before he had reached his sixth year, but the boy found a protector in his maternal uncle, Henry Gascoigne, secretary and confidential agent to two successive dukes of Ormonde Through his influence he was nominated to the Charterhouse in 1684, and there first met with Addison Five years afterwards he proceeded to Oxford, and was a postmaster at Merton when Addison was a demy at Magdalen Their schoolboy friendship was continued at the university, and probably helped to give a more serious turn to Steele's mind than his natural temperament would have taken under different companionship Addison's reverend father also took an interest in the warm-hearted young Irishman, but their combined influence did not steady him sufficiently to keep his impulses within the lines of a regular career, without waiting for a degree he volunteered into the army, and served for some time as a cadet "under the command of the unfortunate duke of Ormonde" This escapade was made without his uncle's consent, and cost him, according to his own account, "the succession to a very good estate in the county of Wexford in Ireland" Still, he did not lack advancement in the profession he had chosen A poem on the funeral of Queen Mary (1695), dedicated to Lord Cutts, colonel of the Coldstream Guards, brought him under the notice of that nobleman, who took the gentleman trooper into his household as a secretary, made him an officer in his own regiment, and ultimately procured for him a captaincy in Lord Lucas's fusiliers His name was noted for promotion by King William, but the king's death took place before anything had been done for Captain Steele He would seem to have remained in the army, though never on active service, for several years longer

Steele probably owed the king's favour to honest admiration of the excellent principles of *The Christian Hero*, his first prose treatise, published in 1701 The "reformation of manners" was a cherished purpose with King William and his consort, which they tried to effect by proclamation and Act of Parliament, and a sensible well-written treatise, deploring the irregularity of the military character, and seeking to prove by examples—the king himself among the number—"that no principles but those of religion are sufficient to make a great man," was sure of attention Steele complained that the reception of *The Christian Hero* by his comrades was not so respectful, they persisted in trying him by his own standard, and would not pass "the least levity in his words and actions" without protest The sensitive and hot-headed "hero" would seem to have been teased into fighting a duel,—his first and last, for he wounded his antagonist dangerously, and from that time was a staunch opponent of affairs of honour His uneasiness under the ridicule of his irreverent comrades had another curious result it moved him to write a comedy "It was now incumbent upon him," he says, "to enliven his character, for which reason he writ the comedy called *The Funeral*" Although, however, it was Steele's express purpose to free his character from the reproach of solemn dulness, and prove that he could write as smartly as another, he showed greater respect for decency than had for some time been the fashion on the stage The purpose, afterwards more fully effected in his famous periodicals, of reconciling wit, good humour, and good breeding with virtuous conduct was already deliberately in Steele's mind when he wrote his first comedy It was produced and published in 1701, was received on the stage with favour, and owing to its comparative purity helped, along with *The Christian Hero*, to commend its author to King William In his next comedy, *The Lying Lover, or the Ladies' Friendship*, produced two years afterwards, in 1703, Steele's moral purpose was directly avowed, and the play, according to his own statement, was "damned for its piety" *The Tender Husband*, produced eighteen months later (in April 1705), though not less pure in tone, was more successful, in this play he gave unmistakable evidence of his happy genius for conceiving and embodying humorous types of character, putting on the stage the parents or grandparents of Squire Western, Tony Lumpkin, and Lydia Languish It was seventeen years before Steele again tried his fortune on the stage with *The Conscious Lovers*, the best and most successful of his comedies, produced in 1722

Meantime the gallant captain had turned aside to another kind of literary work, in which, with the assistance of his friend Addison, he obtained a more enduring reputation There never was a time when literary talent was so much sought after and rewarded by statesmen Addison had already been waited on in "his humble lodgings in the Haymarket," and advanced to office, when his friend the successful dramatist was appointed to the office of gazetteer This was in May 1707 It was Steele's first connexion with journalism The periodical was at that time taking the place of the pamphlet as an instrument for working on public opinion *The Gazette* gave little opening for the play of Steele's lively pen, his main duty, as he says, having been to "keep the paper very innocent and very insipid", but the position made him familiar with a new field of enterprise in which his inventive mind soon discerned materials for a project of

his own *The Tatler* made its first appearance on the 12th of April 1709. It was partly a newspaper, a journal of politics and society, published three times a week. Steele's position as gazetteer furnished him with special advantages for political news, and as a popular habitué of coffee-houses he was at no loss for social gossip. But Steele not only retailed and commented on social news, a function in which he had been anticipated by Defoe and others; he also introduced into *The Tatler* as a special feature essays on general questions of manners and morality. It is not strictly true that Steele was the inventor of the English "essay,"—there were essayists before the 18th century, notably Cowley and Temple; but he was the first to use the essay for periodical purposes, and he and Addison together developed a distinct species, to which they gave a permanent character and in which they had many imitators. As a humbler motive for this fortunate venture Steele had the pinch of impecuniosity, due rather to excess of expenditure than to smallness of income. He had £300 a year from his gazetteership, £100 as gentleman usher to Prince George, £800 from the Barbados estates of his first wife,[1] and some fortune by his second wife—Mrs Mary Scurlock, the "Dear Prue" of his charming letters. But Steele lived in considerable state after this second marriage, and was reduced to the necessity of borrowing before he started *The Tatler*. The assumed name of the editor was Isaac Bickerstaffe, but Addison discovered the real author in the sixth number, and began to contribute in the eighteenth. It is only fair to Steele to state that the success of *The Tatler* was established before Addison joined him, and that Addison contributed to only forty-two of the two hundred and seventy-one numbers that had appeared when the paper was stopped in January 1711.

Only two months elapsed between the stoppage of *The Tatler* and the appearance of *The Spectator*, which was the organ of the two friends from March 1, 1711 till December 6, 1712. Addison was the chief contributor to the new venture, and the history of it belongs more to his life. Nevertheless it is to be remarked as characteristic of the two writers that in this as in *The Tatler* Addison generally follows Steele's lead in the choice of subjects. The first suggestion of Sir Roger de Coverley was Steele's, although it was Addison that filled in the outline of a good-natured country gentleman with the numerous little whimsicalities that convert Sir Roger into an amiable and exquisitely ridiculous provincial oddity. Steele had neither the fineness of touch nor the humorous malice that gives life and distinction to Addison's picture; the Sir Roger of his original hasty sketch has good sense as well as good nature, and the treatment is comparatively commonplace from a literary point of view, though unfortunately not commonplace in its charity. Steele's suggestive vivacity gave many another hint for the elaborating skill of his friend.

The Spectator was followed by *The Guardian*, the first number of which appeared on the 12th of March 1713. It had a much shorter career, extending to only a hundred and seventy-five numbers, of which Steele wrote eighty-two and Addison fifty-three. This was the last of his numerous periodicals in which he had the assistance of the great essayist. But he continued for several years to project journals, under great variety of titles, some of them political, some social in their objects, most of them very short-lived. Steele was a warm partisan of the principles of the Revolution, ardent and earnest in his political as in his other convictions. *The Englishman* was started in January 1714, immediately after the stoppage of *The Guardian*, to assail the policy of the Tory ministry. *The Lover*, started some six weeks later, was more general in its aims; but it gave place in a month or two to *The Reader*, a direct counterblast to the Tory *Examiner*. *The Englishman* was resuscitated for another volume in 1715; and in the same year he projected in rapid succession three unsuccessful ventures,—*Town Talk*, *The Tea Table*, and *Chit-Chat*. Three years later he started his most famous political paper, *The Plebeian*, rendered memorable by the fact that in it he had to contend against his old ally Addison. The subject of controversy between the two life-long friends was Sunderland's Peerage Bill. Steele's last venture in journalism was *The Theatre*, 1719–20, the immediate occasion of which was the revocation of his patent for Drury Lane. So ready was Steele in this kind of enterprise, which he could always conduct single-handed, that apparently whenever he felt strongly on any subject he at once started a journal to give vent to his feelings. Besides these journals he wrote also several pamphlets on passing questions,—on the disgrace of Marlborough in 1711, on the fortifications of Dunkirk in 1713, on the "crisis" in 1714, *An Apology for himself and his Writings* (important biographically) in the same year, on the South Sea mania in 1720.

The fortunes of Steele as a zealous Whig varied with the fortunes of his party. He lost his gazetteership when the Tories came into power in 1710. Over the Dunkirk question he waxed so hot that he threw up a pension and a commissionership of stamps, and went into parliament as member for Stockbridge to attack the ministry with voice and vote as well as with pen. But he had not sat many weeks when he was expelled from the House for the language of his pamphlet on *The Crisis*, which was stigmatized as seditious. The *Apology* already mentioned was his vindication of himself on this occasion. With the accession of the house of Hanover his fortunes changed. Honours and substantial rewards were showered upon him. He was made a justice of the peace, deputy-lieutenant of Middlesex, surveyor of the royal stables, governor of the royal company of comedians—the last a lucrative post, and was also knighted (1715). After the suppression of the Jacobite rebellion he was appointed one of the commissioners of forfeited estates, and spent some two years in Scotland in that capacity. He obtained a patent for a plan for bringing salmon alive from Ireland. Differing from his friends in power on the question of the Peerage Bill in 1718, he was deprived of some of his offices, but when Walpole became chancellor of the exchequer in 1721 he was reinstated. But with all his emoluments the imprudent, impulsive, ostentatious, and generous Steele could never get clear of financial difficulties, and he was obliged to retire from London in 1724 and live in the country. He spent his last years on his wife's estate of Llangunnor in Wales, and, his health broken down by a paralytic seizure, died on the 1st of September 1729.

A selection from Steele's essays has been edited by Mr Austin Dobson, who prefixes a careful and sympathetic memoir. Mr Dobson has since written a fuller biography in Mr Lang's series of *English Worthies*. (W. M.)

STEELYARD, MERCHANTS OF THE, were Hanse merchants who settled in London in 1250 at the steelyard on the river side, near Cosin Lane, now Iron Bridge Wharf. Henry III. in 1259, at the request of his brother Richard, earl of Cornwall, conferred on them important privileges, which were renewed and confirmed by Edward I. It was chiefly through their enterprise that the early trade of London was developed, and they continued to flourish till, on the complaint of the Merchant Adventurers in the reign

[1] The name of this lady—a widow, Mrs Margaret Stretch—and some facts about her have been ascertained by Mr George A. Aitken. See *Athenæum*, May 1, 1886, and Mr Dobson's *Steele*, pp. 51, 218.

of Edward VI, they were deprived of their privileges Though Hamburg and Lubeck sent ambassadors to intercede for them, they were not reinstated in their monopolies, but they succeeded in maintaining a footing in London till expelled by Elizabeth in 1597 Their beautiful guildhall in Thames Street, described by Stow, was made a naval store-house It contained two famous pictures, painted in distemper by Holbein, representing Poverty and Riches, which were presented by the Hanse merchants to Henry, prince of Wales, and came into the possession of Charles I, but are supposed to have perished in the fire which destroyed Whitehall

STEEN, Jan Havicksz (1626–1679), subject-painter, was born at Leyden in 1626, the son of a brewer of the place He studied at Utrecht under Nicholas Knuffer, an historical painter, and about 1644 went to Haarlem, where he worked under Adrian van Ostade and under Jan van Goijen, whose daughter he married in 1649 In the previous year he had joined the painters' guild of the city In 1667 he is said to have been a brewer at Delft, and in 1672 he received municipal authority to open a tavern The accounts of his life, however, are very confused and conflicting Some biographers have asserted that he was a drunkard and of dissolute life, but the number of his works—Van Westrheene, in his *Jan Steen, Étude sur l'Art en Holland*, has catalogued nearly five hundred—is sufficient in itself to disprove the charge His later pictures bear marks of haste and are less carefully finished than those of his earlier period He died at Leyden in 1679

The works of Jan Steen are distinguished by correctness of drawing, admirable freedom and spirit of touch, and clearness and transparency of colouring But their true greatness is due to their intellectual qualities In the wide range of his subjects, and their dramatic character, he surpasses all the Dutch figure-painters, with the single exception of Rembrandt His productions range from the stately interiors of grave and wealthy citizens to tavern scenes of jollity and debauch He painted chemists in their laboratories, doctors at the bedside of their patients, card-parties, marriage feasts, and the festivals of St Nicholas and Twelfth Night,—even religious subjects, though in these he was least successful His rendering of children is especially delightful Dealing often with the coarser side of things, his work is full of humour, he depicts the comedy of human life in a spirit of very genial toleration, but now and again there appear keenly telling touches of satire which recall such a pictorial moralist as Hogarth

The National Gallery contains one picture by Jan Steen,—the Music Master, and other excellent examples of his art are preserved in the Royal, the Bute, the Ashburton, and the Northbrook collections, at Apsley House and Bridgewater House, and in the galleries of The Hague, Amsterdam, and the Hermitage, St Petersburg

STEFFANI, Agostino (1655–1730), ecclesiastic, diplomatist, and musical composer, was born at Castelfranco in 1655, and at a very early age was admitted as a chorister at St Mark's in Venice In 1667 the beauty of his voice attracted the attention of Count Tattenbach, by whom he was taken to Munich, where his education was completed at the expense of Ferdinand Maria, elector of Bavaria, who appointed him "Churfurstlicher Kammer- und Hofmusikus," and granted him a liberal salary After receiving instruction from Johann Kaspar Kerl, and possibly Ercole Bernabei, he was sent in 1673 to study in Rome, where, among other works, he composed six motets, the original MSS of which are now in the Fitzwilliam Museum at Cambridge On his return to Munich in 1674 he published his first work, *Psalmodia Vespertina*, a part of which was reprinted in Martini's *Saggio di Contrappunto* in 1674 In 1675 he was appointed court organist, and in 1680 he was ordained priest, with the title of abbate of Lepsing His ecclesiastical status did not, however, prevent him from turning his attention to the stage, for which, at different periods of his life, he composed works which undoubtedly exercised a potent influence upon the dramatic music of the period Of his first opera, *Marco Aurelio*, produced at Munich in 1681, the only copy known to exist is a MS score preserved in the royal library at Buckingham palace It was followed by *Solone* in 1685, *Servio Tullio* in 1686, *Alarico* in 1687, and *Niobe* in 1688, but of these four last-named works no trace can now be discovered *Niobe* was the last opera Steffani composed at Munich Notwithstanding the favour shown to him by the elector Maximilian Emanuel, he accepted in 1689 the appointment of kapellmeister at the court of Hanover where he speedily gained the goodwill of Ernest Augustus, duke of Brunswick-Luneburg (afterwards raised to the dignity of elector of Hanover), the duchess Sophia Charlotte (afterwards electress of Brandenburg), the philosopher Leibnitz, the abbate Ortensio Mauro, and many men of letters and intelligence, and where, in 1710, he showed great kindness to Handel, who was then just entering upon his glorious career He inaugurated a long series of triumphs in Hanover by composing, for the opening of the new opera-house in 1689, an opera called *Enrico il Leone*, which was produced with extraordinary splendour and achieved an immense reputation For the same theatre he composed *La Lotta d'Ercole con Achilleo* in 1689, *La Superbia d'Alessandro* in 1690, *Orlando Generoso* in 1691, *Le Rivali Concordi* in 1692, *La Libertà Contenta* in 1693, *I Trionfi del Fato* and *I Baccanali* in 1695, and *Briseide* in 1696 The libretto of *Briseide* is by Palmieri Those of most if not all the others are by the abbate Mauro The scores are preserved at Buckingham palace, where, in company with five volumes of songs and three of duets, they form part of the collection brought to England by the elector of Hanover in 1714 But it was not only as a musician that Steffani distinguished himself in his new home The elevation of Ernest Augustus to the electorate in 1692 led to difficulties, for the arrangement of which it was necessary that an ambassador should visit the various German courts, armed with a considerable amount of diplomatic power The accomplished abbate was sent on this delicate mission in 1696, with the title of envoy extraordinary, and he fulfilled his difficult task so well that Pope Innocent XI, in recognition of certain privileges he had secured for the Hanoverian Catholics, consecrated him bishop of Spiga *in partibus infidelium* In 1698 he was sent as ambassador to Brussels, and after the death of Ernest Augustus in the same year he entered the service of the elector palatine, John William, at Dusseldorf, where he held the offices of privy councillor and protonotary of the holy see Invested with these high honours, Steffani could scarcely continue to produce dramatic compositions in public without grievous breach of etiquette But his genius was too real to submit to repression, and in 1709 he ingeniously avoided the difficulty by producing two new operas—*Enea* at Hanover and *Tassilone* at Dusseldorf—in the name of his secretary and amanuensis Gregorio Piva, whose signature is attached to the scores preserved at Buckingham palace Another score—that of *Arminio*—in the same collection, dated Dusseldorf, 1707, and evidently the work of Steffani, bears no composer's name

Steffani did not accompany the elector George to England, but in 1724 the Academy of Antient Musick in London elected him its honorary president for life, and in return for the compliment he sent the association a magnificent *Stabat Mater*, for six voices and orchestra,

and three fine madrigals The MSS of these are still in existence, and the British Museum possesses a very fine *Confitebor*, for three voices and orchestra, of about the same period All these compositions are very much in advance of the age in which they were written, and in his operas Steffani shows an appreciation of the demands of the stage very remarkable indeed at a period at which the musical drama was gradually approaching the character of a mere formal concert, with scenery and dresses But for the MSS at Buckingham palace, these operas would be utterly unknown, but Steffani will never cease to be remembered by his beautiful chamber duets, which, like those of his contemporary Carlo Maria Clari (1669–1745), are chiefly written in the form of cantatas for two voices, accompanied by a figured bass The British Museum possesses more than a hundred of these charming compositions,[1] some of which were published at Munich in 1679 Steffani visited Italy for the last time in 1729, in which year Handel, who always gratefully remembered the kindness he had received from him at Hanover, once more met him at the palace of Cardinal Ottoboni in Rome This was the last time the two composers were destined to meet Steffani returned soon afterwards to Hanover, and died in 1730 while engaged in the transaction of some diplomatic business at Frankfort

STEIBELT, DANIEL (*c* 1760–1823), pianist and composer, was born between the years 1755 and 1765 at Berlin, where he studied, at the expense of the crown prince Frederick William, under Kirnberger Very little is known of his artistic life before 1790, when he settled in Paris, and attained great popularity as a *virtuoso* by means of a pianoforte sonata called *La Coquette*, which he composed, in conjunction with Hermann, for Queen Marie Antoinette, and almost equal credit as a dramatic composer by an opera entitled *Romeo et Juliette*, produced at the Théâtre Feydeau in 1793 In 1796 Steibelt removed to London, where his pianoforte playing attracted an amount of attention which in 1798 was raised to an absolute *furore* by the production of his concerto (No 3, in E♭) containing the famous "Storm Rondo"—a work that ensured his popularity, in spite of the far higher claims of Clementi, Dussek, and John Baptist Cramer, whose attainments as *virtuosi*, composers, and thoroughly accomplished artists were infinitely superior to his own In the following year Steibelt started on a professional tour in Germany, and, after playing with some success in Hamburg, Dresden, Prague, and Berlin, he arrived in May 1800 at Vienna, where, with the arrogance which formed one of the most prominent characteristics of his nature, he challenged Beethoven to a trial of skill, which naturally resulted in his irretrievable discomfiture His position in Germany being no longer tenable after this pitiful failure, he retired to Paris, and during the next eight years lived alternately in that city and in London, where his reputation continued undiminished In 1808 he was invited by the emperor Alexander to St Petersburg, and there he resided, in the enjoyment of a lucrative appointment, until his death on September 20, 1823

Besides his dramatic music, Steibelt left behind him an enormous number of compositions for the pianoforte, many of which exhibit a certain amount of originality, though they can scarcely be regarded as works of genius His playing, though exceedingly brilliant, was wanting in the higher qualities which so strikingly characterized that of his contemporaries, John Cramer and Muzio Clementi, but he was undoubtedly gifted with talents of a very high order, and the reputation he enjoyed was fairly earned and honourably maintained to the end

STEIN, HEINRICH FRIEDRICH KARL, BARON VOM UND ZUM (1757–1831), one of the greatest of German statesmen, and perhaps the most influential forerunner of Bismarck in the creation of German unity, was born at Nassau on October 26, 1757 He was a member of the independent noblesse or knighthood of the German empire (Reichsritterschaft), and his ancient family seat, Burg Stein, lies on a hill rising above the Lahn opposite Nassau In his autobiography he speaks of his parents as "pious and genuinely German," and ascribes to their teaching his own religious and patriotic feelings, his sense of the dignity of his family and order, and his conviction of the duty of devoting his life to the public weal Though the youngest but one of ten children, Stein was selected by his parents as the "Stammhalter," or representative and maintainer of the family name and dignity, and his elder brothers acquiesced in this arrangement

From 1773 to 1777 Stein studied political economy, jurisprudence, and history at the university of Gottingen, where he made his first acquaintance with English institutions, his knowledge and appreciation of which are often manifest in his later career His original intention was to qualify for an appointment in the imperial courts, but this sphere of work was little to his taste, and in 1780 he took the step, somewhat unusual for an imperial knight, of entering the service of Prussia He became an official in the mining department, and by 1784 had risen to be head of the administration of mines and manufactures for Westphalia In 1796 he was made supreme president of the provincial chambers of Westphalia, an appointment which gave him opportunity to evince his great administrative talents In 1785 his administrative career was interrupted for a short time by a diplomatic mission to the elector of Mainz, and in 1786–87 he made a long professional tour in England, chiefly in the mining districts

In 1804 Stein was created a minister of state, with the portfolio of excise, customs, manufactures, and trade In this capacity he abolished the internal customs duties throughout Prussia, and effected several other needed reforms, but he was unable to modify the general disastrous tenour of the Prussian policy, which was now ripening for the catastrophe of Jena. Stein's remonstrances with the king and his strictures upon the course of the administration were couched in the most open and unsparing language, and they were specially directed against the system of government through privy cabinet counsellors, who had practically come to supplant the ministers without possessing either an official knowledge of affairs or a ministerial responsibility He refused to join in the reconstituted ministry after Jena unless this abuse were done away with, and Frederick William III, already wounded by the frankness of Stein's criticism, sent him his dismissal in a most ungracious form (January 3, 1807) When the king, however, found himself left in the lurch by his ally Russia, at the peace of Tilsit (July 9, 1807), he turned in despair to the strong and candid counsellor he had dismissed half a year before, and invited Stein to re-enter his service, practically on his own terms Curiously enough Stein's appointment as minister president was encouraged by Napoleon, who seems to have seen in him merely the clever organizer and financier, who would most easily put Prussia in a position to pay the enormous war indemnity levied on it Stein took office on October 4, 1807, and at once began that weighty series of organic reforms with which his name is most indissolubly connected The emancipation edict appeared on October 9, 1807, a few days after the formal receipt of his powers, and the municipal ordinance was published on November 19, 1808 In the interim he co-operated zealously with Scharnhorst in the reconstitution of the army, carried out a number of important financial and administrative reforms, and prepared the way for a thorough

[1] Add MSS 5055 *sq*

reconstruction of the whole framework of government, which, however, he himself was not to have an opportunity to effect.

Stein's momentous ministry did not last much more than a year. Napoleon soon awoke to the eminently patriotic and energetic character of the man he had incautiously recommended, and an intercepted letter gave him the opportunity to demand Stein's dismissal. Frederick William had no option but to comply, as he shrank from the only possible alternative of an open breach with the French emperor. Stein was proscribed by Napoleon, his property in Westphalia was confiscated, and he himself had to take refuge in Austria from the French troops.[1]

In 1812 the czar Alexander invited Stein to St Petersburg, where he filled the post of unofficial adviser to his imperial majesty on German or rather on anti-Napoleonic affairs; and it would perhaps be difficult to overestimate the influence of the proximity of such a man in keeping Alexander's courage screwed to the sticking point. When the scene of the campaign of 1812 was transferred to Germany, Stein was entrusted with the administration of the Prussian districts occupied by the Russian troops, and he shares with Yorck the merit of arousing East Prussia to take arms against the French, and so of calling the "Landwehr" into existence for the first time. To Stein also mainly belongs the credit of effecting that union of Russia and Prussia (treaty of Kalisch, February 27, 1813) which was perhaps the main factor in the overthrow of Napoleon. After the battle of Leipsic Stein became supreme president of a central commission appointed to administer the lands occupied by the allied armies, in which post he was indefatigable in providing the men and material necessary for a successful prosecution of the war. When the military struggle was over Stein's work was practically done. The two tendencies of absolutism on the one hand and particularism on the other which determined the tone of the Vienna congress were equally repugnant to him, and he took little part in its deliberations. He also refused the invitations of Austria and Prussia to represent them at the Frankfort diet, a makeshift in which he had no confidence or hope. The rest of his life he spent in retirement, sharing his time between Frankfort and his property in Westphalia, and the only office he ever again filled was that of marshal of the provincial estates. In 1819 he founded the society for the publication of the *Monumenta Germaniæ Historica*, which has since done such admirable work. He died on June 29, 1831, in his seventy-fourth year, on his estate of Cappenberg in Westphalia, leaving a family of three daughters. His wife was Countess von Walmoden-Gimborn of Hanover, a granddaughter of George II.

Stein's distinguishing merit as a statesman is that he was practically the first to see the urgent necessity of German unity, to contemplate its realization as possible, and to inaugurate a policy likely to bring it about. That which, now that it has been accomplished by Stein's great successor, seems to us almost a matter of course, was a mere chimera to most of our forefathers, and it required the faculty of a political seer to attain Stein's clear views of future possibilities. Stein saw, too, that the only hope of salvation lay in the people as such,—that he must enlist the sympathies of the nation and raise its moral tone. To this end a series of great and just reforms was necessary. If a deep national sentiment was to be evoked, the people must be freed from feudal burdens; if they were to carry on an effective struggle for independence, they must first acquire personal liberty. His emancipation edict, therefore, which has been called the habeas corpus act of Prussia, abolished serfdom, did away with the distinctions of caste, and abrogated the feudal restrictions upon the free disposition of person and property (compare PRUSSIA, vol. xx. pp. 11, 12). This reform, however, Stein found, in a sense, ready to his hand: it was demanded by the spirit of the times, and can hardly be looked on as a purely individual achievement. His most distinctive work was a great scheme of political reform, in which he contemplated the conversion of the absolute monarchy of Prussia into a free representative state. He wisely began the process by introducing the principle of free local government in his Städte Ordnung, or municipal ordinance. The people had to be roused to take an interest in governing themselves, and it was easier to expand this interest from the local to the national than to work down from the national to the local. Stein did not see much more than this beginning of his plans, but the famous "Political Testament" he drew up on leaving office shows how wide sweeping were the reforms he contemplated. The right of self government was to be extended to the rural communes, and a thorough reform of every branch of the administration was to be effected, while the coping stone of the new edifice was to take the form of a free representative parliament. Time, however, has been on his side, and it is not too much to say with Prof. Von Treitschke that every advance Germany has since made in political life has brought it nearer the ideals of Stein.

The standard work on Stein is the biography by G. H. Pertz, 6 vols., 1849–55, but few English readers will feel the need of going beyond Prof. Seeley's admirable *Life and Times of Stein*, London, 1879, which also contains a full bibliography. (J. F. M.)

[1] The belief that Stein occupied himself during his retirement in propagating his opinions through the "Tugendbund" seems from recent investigations to be erroneous. He had no sympathy with secret societies, and all indications go to show that he rather disapproved of the league than otherwise.

STEINAMANGER (Hung. *Szombathely*, Lat. *Sabaria*), the chief town of the trans-Danubian county of Vas, Hungary, is an old place of some interest. Though it has only 12,000 inhabitants, it is the seat of a Roman Catholic bishop, and has a Dominican convent, a seminary, gymnasium, chamber of advocates, large orphanage, fine theatre, and a number of superior Government offices. The interior of the cathedral is of great beauty, in the Italian style. The town is at the junction of four different railways, and is rapidly rising in importance.

STEINER, JAKOB (1796–1863), one of the greatest geometricians of all ages, was born on the 18th of March 1796 at the Swiss village of Utzendorf (canton Bern). Here he grew up helping his father in his agricultural pursuits, learning to write only at the age of fourteen. At eighteen he became a pupil of Pestalozzi, and afterwards studied at Heidelberg. Thence he went to Berlin, earning a livelihood here as in Heidelberg by giving private lessons. Here he became acquainted with Crelle, who, encouraged by his ability and by that of Abel, then also staying at Berlin, founded his famous *Journal* (1826). After Steiner's publication (1832) of his *Systematische Entwickelungen* he got, through Jacobi's exertions, who was then professor at Königsberg, an honorary degree of that university; and through the influence of Jacobi and of the brothers Alexander and Wilhelm von Humboldt a new chair of geometry was founded for him at Berlin (1834). This he occupied till his death, which took place in Bern on April 1, 1863, after years of bad health.

Steiner's mathematical work was confined to geometry. This he treated synthetically, to the total exclusion of analysis, which he hated, and he is said to have considered it a disgrace to synthetical geometry if equal or higher results were obtained by analytical methods. In his own field he surpassed all his contemporaries. His investigations are distinguished by their great generality, by the fertility of his resources, and by a rigour in his proofs which rivals that of the ancients, so that he has been considered the greatest geometrical genius since the time of Apollonius.

In his *Systematische Entwickelung der Abhängigkeit geometrischer Gestalten von einander* he laid the foundation on which synthetic geometry in its present form rests. He introduces what are now called the geometrical forms (the row, flat pencil, &c.), and establishes between their elements a one-one correspondence, or, as he calls it, makes them projective. He next gives by aid of these projective rows and pencils a new generation of conics and ruled quadric surfaces, "which leads quicker and more directly than former methods into the inner nature of conics and reveals to us the organic connexion of their innumerable properties and mysteries." In this work also, of which unfortunately only one volume appeared instead of the projected five, we see for the first time the

principle of duality introduced from the very beginning as an immediate outflow of the most fundamental properties of the plane, the line, and the point, so that a proof of its correctness is not required

In a second little volume, *Die geometrischen Constructionen ausgeführt mittelst der geraden Linie und eines festen Kreises* (1833), he shows, what had been already suggested by Poncelet, how all problems of the second order can be solved by aid of the straight edge alone without the use of compasses, as soon as one circle is given on the drawing paper

The rest of Steiner's writings are found in numerous papers mostly published in *Crelle's Journal*, the first volume of which contains his first four papers The most important are those relating to algebraical curves and surfaces, especially the short paper *Allgemeine Eigenschaften algebraischer Curven* This contains only results, and there is no indication of the method by which they were obtained, so that, according to Hesse, "they are, like Fermat's theorems, riddles to the present and future generations" Eminent analysts succeeded in proving some of the theorems, but it was reserved to Cremona to prove them all, and that by a uniform synthetic method, in his book on algebraical curves Other important investigations relate to maxima and minima Starting from simple elementary propositions, Steiner advances to the solution of problems which analytically require the calculus of variation, but which at the time altogether surpassed the powers of that calculus Connected with this is the paper *Vom Krummungsschwerpuncte ebener Curven*, which contains numerous properties of pedals and roulettes, especially of their areas

Steiner's papers have been collected and published in two volumes by the Berlin Academy His lectures on synthetic geometry, containing the theory of conics, have been published since his death, edited by Geiser and Schroter Biographical notices are contained in Geiser's pamphlet *Zur Erinnerung an J Steiner* (Schaffhausen, 1874)

STENDAL, a manufacturing town and important railway junction in Prussian Saxony, and the former capital of the Altmark, is picturesquely situated on the Uchte, 33 miles to the north-east of Magdeburg Among the relics of its former importance are the cathedral, built in 1420-24 (though originally founded in 1188) and restored in 1857, the Gothic church of St Mary, founded in 1447, a "Roland column" of 1535, and two fortified gateways, dating from the 13th century The last form the chief remains of the ancient fortifications, the site of which is now mostly occupied by promenades A monument to the archæologist Winckelmann (1717-68) commemorates his birth in the town Stendal is the seat of a large railway workshop, and carries on various branches of textile industry, besides the manufacture of tobacco, machinery, stoves, gold-leaf, &c The earliest printing-press in the Altmark was erected here, and published an edition of the *Sachsenspiegel* in 1488 as its first book The population in 1885 was 16,186

Stendal was founded in 1151 by Albert the Bear, on the site of a Wendish settlement, and soon afterwards acquired a municipal charter Becoming capital of the Altmark and a frequent imperial residence, it rose to a considerable degree of prosperity, in part recently restored to it by its railway connexions When the mark was divided in 1258, Stendal became the seat of the elder or Stendal branch of the house of Ascania, which, however, became extinct in 1320 The original Wends were gradually fused with the later Saxons, although the Platea Slavonica, mentioned in 1475, was still distinguished as the Wenden Strasse in 1567 The population still exhibits a marked Slavonic element

STENOGRAPHY See SHORTHAND

STEPHANUS BYZANTIUS, the author of a geographical dictionary entitled Ἐθνικά, of which, apart from some fragments, we possess only the beggarly epitome of one Hermolaus This work was first edited under the title Περὶ πόλεων (Aldus, Venice, 1502), there are modern editions by Dindorf (1825), Westermann (1839), and Meineke (vol i, 1850) Even in the imperfect form in which we have it the book is of great value from the references to ancient writers which it preserves Hermolaus dedicates his epitome to Justinian, whether the first or second emperor of that name is meant is disputed, but it seems probable that Stephanus flourished in the earlier part of the 6th century

STEPHEN, St, described in late MSS of Acts xxii 20 and in subsequent ecclesiastical tradition as πρωτόμαρτυς, was one of the first seven deacons who were chosen by the church in Jerusalem at the instance of the apostles He is spoken of as "a man full of faith and the Holy Spirit," and, though his official function was rather the "serving of tables" than the ministry of the word, the narrative of the book of Acts shows him to have been principally and pre-eminently a preacher After a brief period of popularity he was accused before the sanhedrin as a blasphemer, and, without being allowed to finish his speech in his own defence, he was hurried without the city walls and stoned to death (c 37 A D) "Devout men"—an expression apparently used to denote the uncircumcised adherents of the synagogue (see Acts x 2)—buried Stephen and made great lamentation over him His martyrdom is commemorated in the Latin Church on December 26 and in the Greek on December 27 Ecclesiastical tradition tells that in the year 415 his remains were discovered by Lucian, priest of Caphar-Gamala near Jerusalem, after being deposited for some time in Jerusalem, they were removed by the younger Theodosius to Constantinople, and thence by Pope Pelagius to Rome Some relics of Stephen were also brought from Palestine to the West by Orosius Their discovery is commemorated on August 3

The ministry and martyrdom of Stephen marked a great crisis in the history of the relations of the Christian church to the Gentile world At first, we are informed, the early disciples, numbering three thousand souls, "had favour with all the people" (Acts ii 47), who protected them against the rulers, elders, and scribes, "for all men glorified God for that which was done" (Acts iv 21), and the people "magnified" the apostles (v 13) It was this great popularity of the disciples of Jesus in Jerusalem that led to the ordination of the deacons Soon a great revulsion of feeling took place Stephen, "full of grace and power," had wrought "great wonders and signs among the people" (vi 8), then suddenly arose "certain of the synagogue," disputing with Stephen, and were "unable to withstand the wisdom and spirit by which he spoke" What was the new and offensive element introduced by Stephen into the apostolic preaching? The accusations against him, and his speech in his own defence, alike show that he was the first to realize with any clearness the greatness of the Christian revolution,—the incompatibility of the Mosaic institutions with the spirituality and freeness of the gospel and with its destiny to become a message of salvation for the whole world The entire drift of his speech is to show the progressive character of revelation, and to show that, as God had often manifested Himself apart from the forms of the law and the synagogue, these could not be held to be of the essence of religion The seed of much that is most distinctive of the Pauline epistles was sown by the preaching of Stephen

STEPHEN I, bishop of Rome from about 254 to 257, followed Lucius I He withdrew from church followship with Cyprian and certain Asiatic bishops on account of their views as to the necessity of rebaptizing heretics (Euseb, *H E.*, vii 5, Cypr, *Epp*, 75) He is also mentioned as having insisted on the restoration of the bishops of Leon and Astorga, who had been deposed for unfaithfulness during persecution but afterwards had repented He is commemorated on August 2 His successor was Sixtus II

STEPHEN II, pope from March 752 to April 757, was in deacon's orders when chosen to the vacant see within twelve days after the death of Zacharias[1] The main

[1] Zacharias died March 15, 752, and a presbyter named Stephen was forthwith chosen to succeed him, who, however, died four days afterwards and before consecration This Stephen is occasionally called Stephen II, the number of popes of the name being thus raised to ten

difficulty of his pontificate was in connexion with the aggressive attitude of Aistulf, king of the Lombards After unsuccessful embassies to Aistulf himself and appeals to the emperor Constantine, he, though in feeble health, set out to seek the aid of Pippin, by whom he was received in the neighbourhood of Vitry le Brulé in the beginning of 754 He spent the greater part of that year at St Denis The result of his negotiations was the Frankish invasion of Aistulf's territory and the famous "donation" of Pippin (see POPEDOM, vol xix p 495, and compare FRANCE, vol ix p 531) The death of Stephen took place not long after that of Aistulf He was succeeded by Paul I

STEPHEN III, pope from August 1, 768 to January 24, 772, was a native of Sicily, and, having come to Rome during the pontificate of Gregory III, gradually rose to high office in the service of successive popes On the deposition of Constantine II, Stephen was chosen to succeed him Fragmentary records are preserved of the council (April 769) at which the degradation of Constantine was completed, certain new arrangements for papal elections made, and the practice of image-worship confirmed The politics of Stephen's reign are obscure, but he inclined to the Lombard rather than to the Frankish alliance He was succeeded by Adrian I

STEPHEN IV, pope from June 816 to January 817, succeeded Leo III, whose policy he continued Immediately after his consecration he ordered the Roman people to swear fidelity to Louis the Pious, to whom he found it prudent to betake himself personally in the following August After the coronation of Louis at Rheims in October he returned to Rome, where he died in the beginning of the following year His successor was Paschal I

STEPHEN V, pope from 885 to 891, succeeded Adrian III, and was in turn succeeded by Formosus In his dealings with Constantinople in the matter of Photius, as also in his relations with the young Slavonic church, he pursued the policy of Nicholas I His pontificate was otherwise unimportant

STEPHEN VI, pope from May 896 to July–August 897, succeeded Boniface VI, and was in turn followed by Romanus He is remembered only in connexion with his conduct towards the remains of Formosus, his last predecessor but one (see FORMOSUS) It excited a tumult, which ended in his imprisonment and his death by strangling

STEPHEN VII (February 929 to March 931) and STEPHEN VIII (July 939 to October 942) were virtually nonentities, who held the pontificate during the so-called "pornocracy" of Theodora and Marozia (see ROME, vol xx p 787–8)

STEPHEN IX, pope from August 1057 to March 1058, succeeded Victor II (Gebhard of Eichstadt) His baptismal name was Frederick, and he was a younger brother of Godfrey, duke of Upper Lorraine, who, as marquis of Tuscany (by his marriage with Beatrice, widow of Boniface, marquis of Tuscany), played a prominent part in the politics of the period Frederick, who had been raised to the cardinalate by Leo IX, discharged for some time the functions of papal legate at Constantinople, and was with Leo in his unlucky expedition against the Normans He shared the vicissitudes of his brother's fortunes, and at one time had to take refuge from Henry III in Monte Cassino Five days after the death of Victor II (who had made him cardinal-priest and abbot of Monte Cassino), he was chosen to succeed him He showed great zeal in enforcing the Hildebrandine policy as to clerical celibacy, and was planning large schemes for the expulsion of the Normans from Italy, and the elevation of his brother to the imperial throne, when he was seized by a severe illness, from which he only partially and temporarily recovered He died at Florence March 29, 1058, and was succeeded by Benedict X

STEPHEN (1105–1154), king of England, the second son of Stephen, earl of Blois, and Adela, daughter of William the Conqueror, was born at Blois in 1105 He obtained the county of Mortain by the gift of his uncle Henry I and that of Boulogne by marriage with Maud, daughter of Count Eustace As one of the chief barons of Normandy he had sworn to aid in securing the succession to the crown of England for his cousin the empress Matilda and her infant son, afterwards Henry II Nevertheless, on the death of Henry I in 1135, Stephen at once crossed over to England, and was welcomed by the citizens of London as king Aided by his brother Henry, bishop of Winchester, and the justiciar, Bishop Roger of Salisbury, he made himself master of the royal treasure, and was formally elected and crowned on St Stephen's day, December 26, 1135 In a brief charter issued at the time of his coronation he promised to observe the laws and liberties of the land A fuller charter, the second of our great charters of liberties, was issued early in 1136 In this document, which was based on that of Henry I, each of the three estates came in for its share of promises, but the leading position of the church and the importance of the aid which it gave the king are shown by the predominant attention paid to ecclesiastical privileges So far all seemed going well, but the troubles of the reign soon began A false report of Stephen's death in the summer of 1136 caused revolts to break out in the east and west of England Roger Bigot seized Norwich, and Baldwin of Redvers occupied Exeter Stephen, who possessed considerable military skill, speedily put down these rebellions, but the outbreak showed the lightness of the feudal bond and the defectiveness of Stephen's title. In 1137 he crossed over into Normandy to defend his dominions there from Geoffrey of Anjou, and was successful enough to make a satisfactory peace, but he returned to find England aflame A mysterious conspiracy was hatched in the diocese of Ely, where the fenlands may have still concealed some remnants of the opposition to Stephen's grandfather David, king of Scotland, who had already taken up arms on behalf of his niece Matilda, but had been bought off by the surrender of Carlisle, marched an army into England and advanced as far as Yorkshire Robert, earl of Gloucester, the strongest of the English nobles, raised the standard of rebellion at Bristol Against these numerous enemies Stephen contrived at first to make head The conspiracy at Ely was nipped in the bud, the Scotch invasion was checked in the battle of the Standard, near Northallerton, in 1138, and even against Robert of Gloucester Stephen won some success But his own weakness and folly proved his ruin In order to conciliate the barons who remained true to him, he allowed them to build castles, each of which became a centre of petty but intolerable tyranny Instead of relying on the support of his English subjects, Stephen surrounded himself with a body of foreign mercenaries, who pillaged all alike He granted earldoms at random, thereby splitting up the royal authority and diminishing the royal revenues Lastly,—and this was the worst mistake of all,—he broke with the church, and especially with the great family of Bishop Roger, who had the administrative machinery in their hands On the ground that they had no right to fortify their castles he arrested the bishops of Lincoln and Salisbury, together with Roger the chancellor, son of the latter He thus enforced the surrender of the castles, but the church, with the new archbishop, Theobald, and Stephen's brother, Henry of Winchester, now legate, at its

head, declared against him Henry called a council, laid formal charges against the king, and threatened to appeal to Rome In the midst of this crisis Matilda and her half-brother, Robert of Gloucester, landed in the south of England, and a civil war began From this time forward, for fourteen dismal years, the land knew no peace It is needless to go into details Neither party was strong enough to deal a final blow at the other The nobility changed sides as they pleased, fighting generally for their own interests or for plunder, bands of freebooters wandered up and down the country, upwards of a thousand castles, each of which was a den of robbers, were erected, the church found threats and persuasion equally ineffective to restore peace and order "Men said openly," we are told by the chronicler, "that Christ and His saints slept" At the battle of Lincoln in 1141 Stephen was taken prisoner After this Matilda was elected queen, but she soon forfeited the allegiance of her supporters The Londoners revolted, the empress fled to Oxford, and the earl of Gloucester was taken prisoner He was exchanged for Stephen, and matters went on as before About 1147 there came a change Matilda left the country, and her son Henry took the lead His predominance was further secured by the death of Robert of Gloucester in 1148 Three years later Henry became count of Anjou on the death of his father, while his marriage with Eleanor of Aquitaine made him one of the most powerful princes in Europe This great accession of strength enabled him to meet Stephen on more than equal terms, and Stephen on the death of his son Eustace was more inclined to peace In November 1153 the treaty of Wallingford brought the long struggle to an end It was agreed that Stephen should reign till his death, and that Henry should succeed him A scheme of reform was drawn up, which Stephen endeavoured, during the short remainder of his reign, to carry out He died on October 25, 1154 A brave man, a good soldier, merciful and generous, but devoid of moral strength and political insight, he was utterly incapable to discharge a task which demanded all the skill and energy of his great successor His nominal reign was a period of anarchy in English history, important only as a full justification for the tyrannies of Henry I and Henry II

STEPHEN, SIR JAMES (1789–1859), historian, was the son of James Stephen, master in chancery, author of *The Slavery of the West India Colonies* and other works, and was born in London 3d January 1789 He was educated at Trinity Hall, Cambridge, graduating B A in 1812, after which he studied for the bar and was called at Lincoln's Inn He obtained an extensive practice as a chancery barrister, being ultimately counsel to the colonial department and counsel to the Board of Trade In 1834 he became assistant under-secretary for the colonies, and shortly afterwards permanent under-secretary On his retirement in 1847 he was made a knight commander of the Bath In 1849 he was appointed regius professor of modern history in the university of Cambridge, having already distinguished himself by his brilliant studies in ecclesiastical biography contributed to the *Edinburgh Review*, which were published that year under the title *Essays in Ecclesiastical Biography and Other Subjects*, a 4th edition, with a short memoir, appeared in 1860 He was also the author of *Lectures on the History of France*, 2 vols, 1851, 3d ed 1857, and *Desultory and Systematic Reading*, a lecture, 1853. He died at Coblentz on the 15th of September 1859

STEPHENS, the incorrect English form of the name of *Estienne*, the distinguished French family of scholars and printers

The founder of the race was HENRI ESTIENNE (d 1520), the scion of a noble family of Provence, who came to Paris in 1502, and soon afterwards set up a printing establishment at the top of the Rue St Jean de Beauvais, on the hill of Sainte Geneviève opposite the law school He died in 1520, and, his three sons being minors, the business was carried on by his foreman Simon de Colines, who in 1521 married his widow

ROBERT ESTIENNE (1503–1559) was Henri's second son After his father's death he acted as assistant to his step father, and in this capacity superintended the printing of a Latin edition of the New Testament in 16mo (1523) Some slight alterations which he had introduced into the text brought upon him the censures of the faculty of theology It was the first of a long series of disputes between him and that body It appears that he had intimate relations with the new Evangelical preachers almost from the beginning of the movement, and that soon after this time he definitely joined the Reformed Church In 1526 he entered into possession of his father's printing establishment, and adopted as his device the celebrated olive tree (a reminiscence doubtless of his grandmother's family of Montolivet), with the motto from the epistle to the Romans (xi 20), *Noli altum sapere*, sometimes with the addition *sed time* In 1528 he married Perrette, a daughter of the scholar and printer Josse Bade (Jodocus Badius), and in the same year he published his first Latin Bible, an edition in folio, upon which he had been at work for the last four years In 1532 appeared his *Thesaurus Linguæ Latinæ*, a dictionary of Latin words and phrases, upon which for two years he had toiled incessantly, with no other assistance than that of Thierry of Beauvais A second edition, greatly enlarged and improved, appeared in 1536, and a third, still further improved, in 3 vols folio, in 1543 Though the *Thesaurus* is now superseded, its merits must not be forgotten It was vastly superior to anything of the kind that had appeared before, it formed the basis of future labours, and even as late as 1734 was considered worthy of being re-edited In 1539 Robert was appointed king's printer for Hebrew and Latin, an office to which, after the death of Conrad Neobar in 1540, he united that of king's printer for Greek In 1541 he was entrusted by Francis I with the task of procuring from Claude Garamond, the engraver and type-founder, three sets of Greek type for the royal press The middle size were the first ready, and with these Robert printed the *editio princeps* of the *Ecclesiasticæ Historiæ* of Eusebius and others (1544) The smallest size were first used for the 16mo edition of the New Testament known as the *O mirificam* (1546), while with the largest size was printed the magnificent folio of 1550 This edition involved the printer in fresh disputes with the faculty of theology, and towards the end of the following year he left his native town for ever, and took refuge at Geneva, where he published in 1552 a caustic and effective answer to his persecutors, under the title *Ad Censuras Theologorum Parisiensium, quibus Biblia a R. Stephano, Typographo Regio, excusa calumniose notarunt, eiusdem R. S Responsio* A French translation, which is remarkable for the excellence of its style, was published by him in the same year (printed in Rénouard's *Annales de l'Imprimerie des Estienne*) At Geneva Robert proved himself an ardent partisan of Calvin, several of whose works he published He died there September 7, 1559

It is by his work in connexion with the Bible, and especially as an editor of the New Testament, that he is on the whole best known The text of his New Testament of 1550, either in its original form or in such slightly modified form as it assumed in the Elzevir text of 1634, remains to this day the traditional text But, as modern

scholars have pointed out, this is due rather to its typographical beauty than to any critical merit The readings of the fifteen MSS which Robert's son Henri had collated for the purpose were merely introduced into the margin The text was still almost exactly that of Erasmus It was, however, the first edition ever published with a critical apparatus of any sort Of the whole Bible Robert printed eleven editions,—eight in Latin, two in Hebrew, and one in French, while of the New Testament alone he printed twelve,—five in Greek, five in Latin, and two in French In the Greek New Testament of 1551 (printed at Geneva) the present division into verses was introduced for the first time The *editiones principes* which issued from Robert's press were eight in number, viz, *Eusebius*, including the *Præparatio Evangelica* and the *Demonstratio Evangelica* as well as the *Historia Ecclesiastica* already mentioned (1544–46), *Moschopulus* (1545), *Dionysius of Halicarnassus* (February 1547), *Alexander Trallianus* (January 1548), *Dio Cassius* (January 1548), *Justin Martyr* (1551), *Xiphilinus* (1551), *Appian* (1551), the last being completed, after Robert's departure from Paris, by his brother Charles, and appearing under his name These editions, all in folio, except the *Moschopulus*, which is in 4to, are unrivalled for beauty Robert also printed numerous editions of Latin classics, of which perhaps the folio *Virgil* of 1532 is the most noteworthy, and a large quantity of Latin grammars and other educational works (many of them written by his friend Maturin Cordier) in the interests of that cause of which he proved himself so stout a champion,—the new learning

CHARLES ESTIENNE (1504 or 1505–1564), the third son of Henri, was, like his brother Robert, a man of considerable learning After the usual humanistic training he studied medicine, and became a doctor of that faculty in the university of Paris In 1540 he accompanied the French ambassador Lazare Baif to Italy in the capacity of tutor to his natural son Antoine, the future poet In 1551, when Robert Estienne left Paris for Geneva, Charles, who had remained a Catholic, took charge of his printing establishment, and in the same year was appointed king's printer He died in 1564, according to some accounts in prison, having been thrown there for debt

His principal works are *Prædium Rusticum*, a collection of tracts which he had compiled from ancient writers on various branches of agriculture, and which continued to be a favourite book down to the end of the 17th century, *Dictionarium Historicum ac Poeticum* (1553), the first French encyclopædia, *Thesaurus Ciceronianus*, and *Paradoxes*, a free version of the *Paradossi* of Ortensio Landi, with the omission of a few of the paradoxes and of the impious and indecent passages (Paris, 1553, Poitiers, 1553) He was also the author of a treatise on anatomy and of several small educational works

HENRI ESTIENNE (1528–1598), sometimes called "Henri II," was the eldest son of Robert In the preface to his edition of Aulus Gellius (1585), addressed to his son Paul, he gives an interesting account of his father's household, in which, owing to the various nationalities of those who were employed on the press, Latin was used as a common language, being understood and spoken more or less by every member of it, down to the maid-servants Henri thus picked up Latin as a child, but at his special request he was allowed to learn Greek as a serious study before Latin At the age of fifteen he became a pupil of Pierre Danès, at that time the first Greek scholar in France Two years later he began to attend the lectures of Jacques Toussain, one of the royal professors of Greek, and in the same year (1545) was employed by his father to collate a MS of Dionysius of Halicarnassus In 1547, after attending for a time the lectures of Turnèbe, Toussain's successor, he went to Italy, where he spent two years in hunting for and collating MSS and in intercourse with learned men In 1550 he was in England, where he was favourably received by Edward VI Thence he went to Flanders, where he learnt Spanish. In 1551 he joined his father at Geneva, which henceforth became his home In 1554 he gave to the world, as the firstfruits of his researches, two first editions, viz, a tract of Dionysius of Halicarnassus and *Anacreon*, both printed by his uncle Charles In 1556 Henri was again in Italy, where he discovered at Rome ten new books (xi–xx) of Diodorus Siculus In 1557 he issued from the press which in the previous year he had set up on his own account at Geneva three first editions, viz, *Athenagoras*, *Maximus Tyrius*, and some fragments of Greek historians, including Appian's Ἀννιβαλική and Ἰβηρική, and an edition of Æschylus, in which for the first time the *Agamemnon* was printed in entirety and as a separate play In 1558 he was appointed printer to Huldrich Fugger, one of the celebrated family of Augsburg bankers, a post which he held for ten years In 1559 he printed a Latin translation from his own pen of Sextus Empiricus, and an edition of Diodorus Siculus with the new books In 1566 he published his best known French work, the *Apologie pour Hérodote*, or, as he himself called it, *L'Introduction au Traité de la Conformité des Merveilles Anciennes avec les Modernes ou Traité préparatif à l'Apologie pour Hérodote*. Some passages in the original edition being considered objectionable by the Geneva consistory, he was compelled to cancel the pages containing them The book became highly popular Within sixteen years twelve editions were printed In 1572 Henri published the great work upon which he had been labouring for many years, the *Thesaurus Græcæ Linguæ*, in 5 vols folio The publication in 1578 of his *Dialogues du nouveau François Italianizé* brought him into a fresh dispute with the consistory To avoid their censure he went to Paris, and resided at the French court for the whole of 1579 On his return to Geneva in the spring of 1580 he was summoned before the consistory, and, proving contumacious, was imprisoned for a week From this time his life became more and more of a nomad one He is to be found at Basel, Heidelberg, Vienna, Pesth, everywhere but at Geneva, these journeys being undertaken partly in the hope of procuring patrons and purchasers for his books (for the large sums which he had spent on such publications as the *Thesaurus* and the *Plato* of 1578 had almost ruined him), partly from the increasing restlessness of his disposition But the result of these long absences was that his press stood nearly at a standstill A few editions of classical authors were brought out, but each successive one showed a falling off Such value as the later ones had was chiefly due to the notes furnished by Casaubon, who in 1586 had married Henri's daughter Florence Henri's last years were marked by ever-increasing infirmity of mind and temper In 1597 he left Geneva for the last time After visiting Montpellier, where Casaubon was now professor, he made for Paris, but was seized with sudden illness at Lyons, and died there in his seventieth year, at the end of January 1598.

Few men have ever served the cause of learning more devotedly For over thirty years the amount which he produced, whether as printer, editor, or original writer, was enormous The productions of his press, though printed with the same beautiful type as his father's books, are, owing to the poorness of the paper and ink, inferior to them in general beauty The best, perhaps, from a typographical point of view, are the *Poetæ Græci Principes* (folio, 1566), the *Plutarch* (13 vols 8vo, 1572), and the *Plato* (3 vols folio, 1578) It was rather Henri Estienne's scholarship which gave value to his editions He was not only his own press-corrector but his own editor Though by the latter half of the 16th century nearly all the important Greek and Latin authors that we now possess had been published, his untiring activity still found some gleanings Eighteen first editions of Greek authors and one of a Latin author are due to his press The most important have been already mentioned Henri's reputation as a scholar and editor has increased of late years His familiarity with the Greek language has always been admitted to have been quite exceptional, but he has been accused of want of taste and judgment, of carelessness and rashness Special censure has been passed on his *Plutarch*, in which he is said to have introduced conjectures of his own into the text, while pretending to have derived them from MS authority But a recent editor, Sintenis, has shown that, though like all the other editors of his day he did not give references to his authorities, every one of his supposed conjectures can be traced to some MS Whatever may be said as to his taste or his judgment, it seems that he was both careful and scrupulous, and that he only resorted to conjecture when authority failed him And, whatever the merit of his conjectures,

he was at any rate the first to show what conjecture could do towards restoring a hopelessly corrupt passage. The work, however, on which his fame as a scholar is most surely based is the *Thesaurus Græcæ Linguæ*. After making due allowance for the fact that considerable materials for the work had been already collected by his father, and that he received considerable assistance from the German scholar Sylburg, he is still entitled to the very highest praise as the producer of a work which was of the greatest service to scholarship and which in those early days of Greek learning could have been produced by no one but a giant. Two editions of the *Thesaurus* have been published in this century—at London by Valpy (1815–25) and at Paris by Didot (1831–63). It was one of Henri Estienne's great merits that, unlike nearly all the French scholars who preceded him, he did not neglect his own language. While Budé wrote French with difficulty and considered it hardly a fit language for a scholar to use, Henri Estienne was loud in its praises and gave practical proof of its capabilities. Of his French writings three were devoted to this theme —(1) *Conformité du Langage François avec le Grec* (published in 1575, but without date; ed. L. Feugère, 1850), in which French is shown to have, among modern languages, the most affinity with Greek, the first of all languages; (2) *Deux Dialogues du nouveau François Italianizé* (Geneva, 1578; reprinted, 2 vols., 1883), directed against the fashion prevailing in the court of Catherine de' Medici of using Italian words and forms; (3) *Project du Livre Intitulé de la Precellence du Langage François* (Paris, 1579; ed. Feugère, 1853), which treats of the superiority of French to Italian. An interesting feature of this tract is the account of French proverbs, and, Henry III having expressed some doubts as to the genuineness of some of them, Henri Estienne published, in 1594, (4) *Les Premices ou le I livre des Proverbes Epigrammatizez* (never reprinted and very rare). Finally, there remains (5) the *Apologie pour Hérodote*, the work by virtue of which Henri Estienne belongs to literature. The ostensible object of the book is to show that the strange stories in Herodotus may be paralleled by equally strange ones of modern times. Virtually it is a bitter satire on the writer's age, especially on the Roman Church. Put together without any method, its extreme desultoriness makes it difficult to read continuously, but the numerous stories, collected partly from various literary sources, notably from the preachers Menot and Maillard, partly from the writer's own multifarious experience, with which it is packed, make it an interesting commentary on the manners and fashions of the time. But satire, to be effective, should be either humorous or righteously indignant, and, while such humour as there is in the *Apologie* is decidedly heavy, the writer's indignation is generally forgotten in his evident relish for scandal. The style is, after all, its chief merit. Though it bears evident traces of hurry, it is, like that of all Henri Estienne's French writings, clear, easy, and vigorous, uniting the directness and sensuousness of the older writers with a suppleness and logical precision which at this time were almost new elements in French prose. An edition of the *Apologie* has recently been published by Liseux (ed. Ristelhuber, 2 vols., 1879), after one of the only two copies of the original uncancelled edition that are known to exist. The very remarkable political pamphlet entitled *Discours Merveilleux de la Vie et des Déportements de Catherine de Médicis*, which appeared in 1574, has been ascribed to Henri Estienne, but the evidence both internal and external is conclusive against his being the author of it. Of his Latin writings the most worthy of notice are the *De Latinitate falso suspecta* (1576), the *Pseudo Cicero* (1577), and the *Nizoliodidascalus* (1578), all three written against the Ciceronians, and the *Francofordiense Emporium* (1574), a panegyric on the Frankfort fair (reprinted with a French translation by Liseux, 1875). He also wrote a large quantity of indifferent Latin verses, including a long poem entitled *Musa Monitrix Principum* (Basel, 1590).

The primary authorities for an account of the Estiennes are their own works. In the garrulous and egotistical prefaces which Henri was in the habit of prefixing to his editions will be found many scattered biographical details. Twenty-seven letters from Henri to John of Crafftheim (Crato) (ed. F. Passow, 1830) have been printed, and there is one of Robert's in Herminjard's *Correspondance des Réformateurs dans les Pays de Langue Française* (7 vols. published), while a few other contemporary references to him will be found in the same work. The secondary authorities are Janssen van Almeloveen, *De Vitis Stephanorum* (Amst., 1683); Maittaire, *Stephanorum Historia* (Lond., 1709); A. A. Rénouard, *Annales de l'Imprimerie des Estienne* (2d ed., Paris, 1843); the article on Estienne by A. F. Didot in the *Nouv. Biog. Gén.*; and an article by Mark Pattison in the *Quart. Rev.* for April 1865. There is a good account of Henri's *Thesaurus* in the *Quart. Rev.* for January 1820, written by Bishop Blomfield. (A. A. T.)

STEPHENS, ALEXANDER HAMILTON (1812–1883), American statesman, was born in Georgia, February 11, 1812. In spite of many difficulties imposed by poverty and ill-health, he became a lawyer and politician of great reputation and popularity. He was one of the Whig leaders of his State until about 1850, and then drifted into the Democratic party through the rising discussions of slavery, serving in Congress from 1843 until 1859. In 1860 he opposed secession warmly; but when his State had seceded he "followed his State," and was elected vice-president of the Confederate States. Whatever there was of opposition to the despotic tendencies of Jefferson Davis gathered around Stephens as a centre; and the vice-president was never an influential member of the Confederate administration. His popularity in Georgia was unbounded, and he was elected representative in Congress in 1877–82, and governor, 1882–83, dying in office. In person he was small and extremely emaciated, seldom weighing more than 90 pounds, and always in delicate health; but his powers as an orator were remarkable.

Cleveland's *A. H. Stephens in Public and Private* and Johnston and Browne's *Life of A. H. Stephens* are the main authorities for Stephens's life. His political opinions are fully given in his work, *The War between the States*.

STEPHENS, JOHN LLOYD (1805–1852), traveller, was born 28th November 1805, at Shrewsbury, N.J., United States. Having been admitted to the bar, he practised his profession for about eight years in New York city. In 1834, the state of his health rendering it advisable that he should travel, he visited Europe, and for two years made a tour through many countries of that continent, extending his travels to Egypt and Syria. On his return to New York he published (under the name of "George" Stephens) in 1837 *Incidents of Travel in Egypt, Arabia Petræa, and the Holy Land*. This work was followed next year by the publication, also in two volumes, of *Incidents of Travel in Greece, Turkey, Russia, and Poland*. In 1839 Stephens arranged with Frederick Catherwood of London, who had accompanied him on some of his travels, and illustrated the above-mentioned publications, that they should make an exploration together in Central America, with a view to discovering and examining ancient art said to exist in the dense forests of that tropical region. Stephens, meantime, was appointed United States minister to Central America. The joint travels of Stephens and F. Catherwood occupied some eight months in 1839 and 1840. As the result of these researches Stephens published in 1841 *Incidents of Travels in Central America, Chiapas, and Yucatan*. In the autumn of 1841 the two travellers made a second exploration of Yucatan, the fruits of which were gathered up in a work published by Stephens in 1843,—*Incidents of Travel in Yucatan*. This work describes the most extensive travels executed till that date by a stranger in the peninsula, and, as the author claims, "contains account of visits to forty-four ruined cities or places in which remains or vestiges of ancient populations were found." It fixed the sites of many prehistoric cities and supplied correct delineations of their existing monuments. This publication enjoyed a wide popularity, and made such an impression on Prescott the historian that he urged Stephens to prosecute his researches of American antiquities in Peru. Stephens was, however, disinclined to so distant an expedition. He became a director of the newly-formed American Ocean Steam Navigation Company, which established the first American line of trans-Atlantic steamships. He visited Panama to reconnoitre the ground with a view to the construction of a railway across the isthmus, and, first as vice-president and then as president of the Panama Railway Company, spent the greater part of two years in superintending the project. His health was, however, entirely undermined by his long and incautious exposure to the deadly climate of Central America, and he died at New York on the 10th October 1852.

Stephens made no pretensions to the title of a scientific traveller. He had, however, a natural curiosity after all kinds of human knowledge, shrewd and accurate powers of observation, and a more than common measure of perseverance, tact, and resource.

STEPHENSON, GEORGE (1781–1848), perfecter of the locomotive, was the son of Robert Stephenson, fireman of a colliery engine at Wylam, near Newcastle, where he was born 9th June 1781. In boyhood he was employed as a cowherd, and occupied his leisure in erecting clay engines and similar mechanical amusements. Afterwards he drove the ginhorse at a colliery, and in his fourteenth year became assistant to his father in firing the engine at a shilling a day. He set himself diligently to qualify himself for higher duties, and in his seventeenth year was appointed engineman or plugman. As yet he was unable to read, but, stimulated by the desire to obtain fuller information regarding the wonderful inventions of Boulton and Watt, he began in his eighteenth year to attend a night school, and soon made remarkably rapid progress. In 1801 he obtained the situation of brakesman, and in 1812 was appointed engine wright at Killingworth high pit at a salary of £100 a year. Meantime he had been employing his leisure in watch and clock cleaning, in studying mechanics, and in various experiments with a view of solving the difficulties connected with the construction of a satisfactory locomotive. Having obtained permission from Lord Ravensworth, the principal partner of the Killingworth colliery to incur the outlay for constructing a "travelling engine" for the tramroads between the colliery and the shipping port nine miles distant, he made a successful trial with the engine, which he named "My Lord," 25th July 1814. Setting himself diligently to improve his invention, he thoroughly satisfied himself that for the proper success of the locomotive a railway as nearly as possible level was an essential condition. In 1822 he succeeded in impressing with the importance of his invention the projectors of the Stockton and Darlington Railway, who had contemplated using horses for their waggons, and was appointed engineer of the railway, with liberty to carry out his own plans, the result being the opening, 27th September 1825, of the first railway over which passengers and goods were carried by a locomotive. The success of the Stockton and Darlington Railway led to the employment of Stephenson in the construction of the Liverpool and Manchester Railway, which, notwithstanding prognostications of failure by the most eminent engineers of the day, he carried successfully through Chat Moss. He also succeeded in persuading the directors to give the locomotive a trial, and, as his improved invention, the "Rocket," during her trial trip made 29 miles an hour, his suggestion met with complete approval, with the opening of the line, 15th September 1830, the modern era of railways may be said to have been definitely inaugurated. While his experiments in connexion with locomotives were in progress, the construction of a safety lamp for use in mines occupied much of his attention. There can be no doubt regarding the justice of his claims to be considered the first inventor of the tube safety lamp, notwithstanding that the name of Sir Humphry Davy has been chiefly associated with the discovery. In recognition of the "valuable service he had thus rendered to mankind," subscriptions were in 1815 collected in behalf of Stephenson which amounted to £1000, a sum which he found of great convenience in connexion with his locomotive experiments. Stephenson was closely connected with the more important of the railway projects which the success of the Liverpool and Manchester line called into existence, but he strongly disapproved of the railway mania which ensued, and predicted that only ruin could result from the prevalent disposition towards railway speculation. He was frequently consulted in regard to the construction of foreign railways, and in this connexion visited Belgium and Spain in 1845. Towards the close of his life he retired from active duties, and at his residence at Tupton House, Chesterfield, interested himself chiefly in farming and horticultural pursuits. He died 12th August 1848.

See *Story of the Life of George Stephenson*, by Samuel Smiles, 1857, new ed 1873, and Smiles's *Lives of British Engineers*, vol iii.

STEPHENSON, ROBERT (1803–1859), engineer, son of the preceding by his first wife Fanny Henderson, was born at Willington Quay, 16th October 1803. Remembering his own early difficulties owing to deficient instruction, his father bestowed special care on his education, sending him in his twelfth year to attend Mr Bruce's school in Percy Street, Newcastle, where he remained about four years. In 1819 he was apprenticed to a coalviewer at Killingworth to learn the business of the colliery, after which, to perfect his training in technical science, he was sent in 1822 to attend the science classes at the university of Edinburgh. On his return he assisted his father in the survey of various railway lines, but in 1824 he accepted an engagement to take charge of the engineering operations of the Columbian Mining Association of London. On account of the harassing difficulties of the situation he resigned it in 1827, and after his return to England undertook the management of his father's factory in Newcastle, greatly aiding him in the improvement of his locomotives, the result being the construction of the "Rocket," which firmly established the practicability of steam locomotion on railways. Subsequently his services were in great request as a railway engineer, and after the retirement of his father he was regarded as the chief authority on the subject. In this connexion his most remarkable achievements were his railway viaducts on the tubular system, constructed with the aid of the practical knowledge of Sir William Fairbairn, and justly characterized as "the greatest discovery in construction in our day." Among his more notable bridges are the Royal Border bridge at Berwick-on-Tweed, the high-level bridge at Newcastle-on-Tyne, the Britannia tubular bridge over the Menai Straits, the Conway tubular bridge, and the Victoria tubular bridge over the St Lawrence, Canada. In 1847 he entered the House of Commons as member for Whitby. He was frequently consulted in the construction of foreign railways, and was decorated for his services by the king of Belgium, the king of Sweden, and the emperor of the French. In 1855 he was elected president of the Institute of Civil Engineers. He died 12th October 1859, and was buried in Westminster Abbey.

See *The Story of the Life of George Stephenson, including a Memoir of his Son Robert Stephenson*, by Samuel Smiles, 1857, new ed 1873; Jeaffreson, *Life of Robert Stephenson*, 2 vols, 1864; and Smiles's *Lives of British Engineers*, vol iii.

STEREOCHROMY. See SILICA.

STEREOSCOPE is an optical instrument for representing in apparent relief and solidity all natural objects by uniting into one image two representations of these objects as seen by each eye separately. That the two eyes form different images of any objects which are near enough to have dissimilar perspective projections has been long known, and may be readily tested by any one. Euclid proved it geometrically with reference to a sphere (26th, 27th, and 28th theorems of his *Treatise on Optics*); Galen showed how the demonstration might be made.[1] PORTA (*q v*), in his work on *Refraction*, also writes on the subject, and Leonardo da Vinci adduced the want of correspondence between the parts of the background intercepted by a near object seen by the two eyes singly "as the reason why no painting can show a *rilievo* equal to that of natural objects seen by both eyes within a moderate distance."[2] In 1613 Aguilonius, a Jesuit, in his work on *Optics*, attributed the union of the two unlike pictures into

[1] *De Usu Partium Corporis Humani*, Lyons, 1550, p 593.
[2] *Trattata della Pictura, Scultura, ed Architettura*, Milan, 1584.

a clear image to a "common sense" which gave its aid equally to each eye,—this common sense being specially exerted when the object is placed much nearer to one eye than to the other, so that the sizes as well as the forms of the two retinal pictures are sensibly different The subject was merely touched by various other writers after Aguilonius until 1775, when Harris[1] observes "We have other helps for distinguishing prominences of small parts besides those by which we distinguish distances in general, as to their degrees of light and shade, and the prospect we have round them Again, by the parallax, on account of the distance betwixt our eyes, we can distinguish, besides the front part, the two sides of a near object not thicker than the said distance, and this gives a visible rilievo to such objects, which helps greatly to raise or detach them from the plane in which they lie Thus the nose on a face is the more remarkably raised by our seeing both sides of it at once" This was undoubtedly a considerable step towards a sound theory of binocular vision, but it cannot be said to have anticipated the invention of the stereoscope This instrument owes its origin entirely to the experimental researches of Sir Charles Wheatstone on binocular vision, and the following passage from Mayo's *Outlines of Human Physiology*, p 288, published in 1833, is the first clear enunciation of the principle on which it is constructed —"A solid object, being so placed as to be regarded by both eyes, projects a different perspective figure on each retina, now if these two perspectives be actually copied on paper, and presented one to each eye, so as to fall on corresponding parts, the original solid figure will be apparently reproduced in such a manner that no effort of the imagination can make it appear as a representation on a plane surface" Sir Charles Wheatstone's "Contributions to the Physiology of Vision, Part the First" appeared in the *Philosophical Transactions* of 1838, but this paper was the result of investigations extending over a period of years, and there is evidence that reflecting stereoscopes were constructed for Wheatstone by Newman, a well-known philosophical instrument maker, so early as the winter of 1832 Wheatstone no doubt also, as early as 1845, employed photographic pictures for his reflecting stereoscope The subject was taken up by Sir David Brewster, and was developed more particularly in two papers read to the Royal Society of Edinburgh in January 1843 and April 1844 These researches led Brewster to the invention of the lenticular or refracting stereoscope The discoveries of Daguerre and Talbot, and the rapid development of the art of photography, enabled photographs to be taken suitable for the stereoscope, thus superseding the geometrical drawings previously employed, and in 1849 Duboscq, a Parisian optician, began the manufacture of lenticular stereoscopes and executed a series of binocular daguerrotypes of living individuals, statues, bouquets of flowers, and objects of natural history For many years the refracting stereoscope of Brewster was one of the most popular of scientific instruments, and was to be found, along with an appropriate collection of pictures, in every drawing-room, but of late years it has somewhat fallen into the background, and the manufacture by photographers of stereoscopic views now forms but a small portion of their work Whilst much credit is due to Brewster for his writings on binocular vision, and for the efforts he made to introduce the stereoscope to the public, there is no doubt that Wheatstone was not only the real inventor of the instrument but he also laid down in his paper published in 1838, and in a second contribution which appeared in the *Philosophical Transactions* in 1852, the true principles of binocular vision[2]

When we look at an external object with both eyes it is seen generally as a single object, although there must be two retinal pictures, one for each eye This depends on the fact that the excitation of certain associated spots on the two retinæ is referred to the same point in space, or, in other words, that the luminous impression which originates by the irritation of two associated points appears as one point in the visual field Such associated points or areas of the retina are said to be corresponding or identical When an object is seen single by two eyes, the two images must fall on corresponding points of the retina If one eye be pushed to the side, the image on the retina of that eye is displaced from its appropriate identical point, and a double image is the result Now the term *horopter* is applied to represent an imaginary surface containing "all those points of the outer world from which rays of light passing to both eyes fall upon identical points of the retina, the eyes being in a certain position" The horopter varies with the different positions of the eyes (see EYE, vol viii p 826) But it is a familiar experience that we not only see a single object with two eyes, but the object, say a cube or a book lying on the table, is seen in relief, that is, we take cognizance of the third dimension occupied by the body in space, although the two retinal pictures are on a plane It is clear that the two images of the object which do not coincide with the horopter cannot be completely united so as to furnish one single visual impression Further, it can readily be demonstrated that the two retinal pictures are dissimilar, and yet the two images are fused into one and give the impression of a single object occupying three dimensions To explain these phenomena, Wheatstone put forward the theory that the mind completely fused the dissimilar pictures into one, and that whenever there occurs such complete mental fusion of images really dissimilar, and incapable of mathematical coincidence, the result is a perception of depth of space, or solidity, or relief The objection to this theory as stated by Wheatstone is that complete fusion does not take place It is always possible by close analysis of visual perceptions to distinguish between the two retinal pictures Further, if the fusion is mental, as stated by Wheatstone, it is an example of unconscious cerebration Another explanation has been suggested by Brucke[3] When we look at objects near at hand the optic axes are converged strongly, and they become less and less converged as we gaze at objects farther and farther away There is thus a series of axial adjustments, the necessary muscular movements giving rise to definite sensations, by which we estimate the relative distance of objects in the field of view A man with one eye cannot judge by this method We habitually depend upon binocular vision for the guidance of all such movements as require an exact estimate of the respective proximity of two or more objects "A very good test experiment is to suspend a curtain ring in such a manner as to present its edge at the distance of four or five feet from the eye, and then to try to push sideways through its hoop the curved handle of a walking stick held by the lower end, in this

[3] This theory is usually attributed to Brucke, but something very similar to it was taught by Brewster Brewster, however, did not attach importance to muscular sensations as an element in the question, and was content with pointing out that, in looking at the stereoscopic pictures of a bust, for example, "the eyes will instantly, by means of their power of convergence, unite the separated points of the eyes, and then the still more separated points of the ears, running over each part of the bust with the rapidity of lightning, and uniting all the corresponding points in succession, precisely as it does in looking at the bust itself" See his article "Stereoscope," in *Encyc. Britan*, 8th ed, vol. xx p 689

feat, which can be readily accomplished under the guidance of binocular vision, large odds may be laid that success will not be attained when one eye is closed, until a succession of trials shall have enabled the experimenter to measure the distance of the ring by the muscular movements of his arm.[1] According to Brucke, the two eyes are continually in a state of motion, and their position of convergence, now greater now less, passes from one side to the other, so that the observer combines successively the different parts of the two pictures, thus giving rise to sensations of depth of space and of subjects standing out in relief. Brucke's theory, in short, is that our perception of depth depends on the fusion of muscular sensations, or rather of nervous impressions arising from the muscles of the eyeballs. It was, however, pointed out by Dove that the sensation of relief, solidity, or perspective is perfect even when natural objects or stereoscopic pictures are seen momentarily by an electric flash lasting only $\frac{1}{24,000}$ of a second, during which time it is inconceivable that there can be any change in the degree of convergence of the optic axes. This experiment is fatal to Brucke's theory, and Wheatstone was right in asserting that the sensation of relief is instantaneous. A third theory is that of Joseph Le Conte, advanced in 1871, and thus stated by himself:—"All objects or points of objects either beyond or nearer than the point of sight are doubled, but differently,—the former homonymously, the latter heteronymously. The double images in the former case are united by less convergence, in the latter case by greater convergence, of the optic axes. Now, the observer knows instinctively and without trial, in any case of double images, whether they will be united by greater or less optic convergence, and therefore never makes a mistake, or attempts to unite by making a wrong movement of the optic axes. In other words, the eye (or the mind) instinctively distinguishes homonymous from heteronymous images, referring the former to objects beyond, and the latter to objects this side of, the point of sight."[2] Thus, according to Le Conte, the mind perceives relief *instantly* but not *immediately*, and it does so by means of double images. This theory does not possess the merit of simplicity, and, whilst it may explain the phenomenon of relief as experienced by those who have been specially trained to the analysis of visual perceptions, it does not satisfactorily account for the experience of everyday life. We are therefore obliged to fall back on the theory of Wheatstone, somewhat modified, namely, that there are, behind the phenomena referred to the retina, psychical operations, unconsciously performed, which fuse together the results of the retinal impressions. In the language of Hermann, "corresponding points are therefore such points as furnish images, which, as experience teaches, are habitually combined or fused. But, as it appears necessary to effect these combinations in order to obtain correct impressions of objects, we get into the habit of fusing also the images of the two not perfectly corresponding points which, under ordinary circumstances, we should perceive as double. It can easily be demonstrated that simultaneous images which fall upon corresponding points are not united, although it is true that they do not form second images. When the mind must unite images which do not fall upon corresponding points, the process must be associated with the conception that the corresponding points in the object occupy the situation for which the eye would have to be arranged, in order that the image should coincide."[3]

To obtain binocular pictures suitable for the stereoscope, the camera must be placed successively in two points of the circumference of a circle of which the object is the centre, and the points at which the camera is so placed must have the angular distance representing the convergence of the optic axes when the object is to be viewed in the stereoscope. For example, if the pictures are to be seen in the stereoscope at a distance of 8 inches before the eyes, the convergence will be 18°, and the camera must be stationed at two points on the circle at the same angular distance. This *distance* of the camera from the object only affects the *magnitude* of the picture. Usually two cameras are employed, fixed at the proper angular positions. Wheatstone gives the following table of the inclination of the optic axes at different distances, and it also shows "the angular positions of the camera required to obtain binocular pictures which shall appear at a given distance in the stereoscope in their true relief."

Inclination of the optic axes	2°	4°	6°	8	10°	12	14	16	18	20°	22	24°	26°	28°	30
Distance in inches	71·5	35·7	23·8	17·8	13·2	11·8	10·1	8·8	7·8	7·0	6·4	5·5	5·4	5·0	4·6

"The distance is equal to $\frac{1}{2}\alpha$ cotang $\frac{1}{2}\theta$,—α denoting the distance between the two eyes and θ the inclination of the optic axes" (Wheatstone, *Scientific Papers*, p. 270).

Suppose two stereoscopic pictures thus taken are presented to the two eyes, it is possible by an effort so to converge the eyes as to throw the images on corresponding points, and when this is done the objects are seen in relief (fig. 1). Such an effort, however, soon causes fatigue, and few persons can so control their eyes and keep them in the forced position as to view the pictures in their natural perspective with any comfort. The object of all stereoscopes is to throw the two pictures on corresponding points with the eyes in an ordinary position.

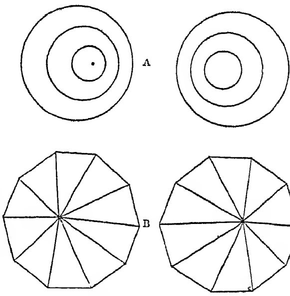

FIG. 1.—Stereoscopic figures. A, cone; B, ten-sided pyramid.

The principle of Wheatstone's reflecting stereoscope is illustrated in fig. 2. It consisted of two plane mirrors, about 4 inches square, fixed in frames and so adjusted that their backs form an angle of 90° with each other. These mirrors are fixed to an upright against the middle line of a vertical board cut away so as to allow the eyes to be placed before the mirrors. On each side there is a panel bearing a groove above and below into which the corresponding pictures can be slid. Mechanical arrangements also exist for the purpose of moving the pictures to or from the mirrors and also for inclining the pictures at any angle (fig. 3). There is one position in which the binocular image will be immediately seen single, of its proper size, and without fatigue, "because in this position only the ordinary relations between the magnitude of the pictures in the retina, the inclination of the optic axes, and the adaptation of the eye to distinct vision at different distances are preserved" (Wheatstone). Although somewhat cumbrous, the reflecting stereoscope is a most useful instrument, and enables one

to perform a greater variety of experiments on binocular vision than can be carried out easily with the more common form.

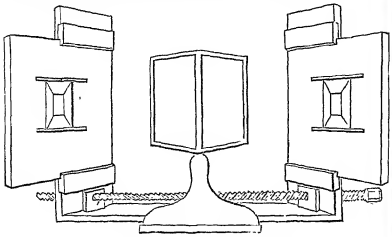

FIG. 3.—Wheatstone's Reflecting Stereoscope.

Wheatstone also invented a form of stereoscope in which the pictures were brought on corresponding points of the retina by refraction instead of by reflexion. This had a form very like the ordinary stereoscope, but, instead of lenses in the apertures to which the eyes are directed, it had "a pair of glass prisms having their faces inclined 15° and their refractive angles turned towards each other. . . . A pair of plate-glass prisms, their faces making with each other an angle of 12°, will bring two pictures, the corresponding points of which are 2½ inches apart, to coincide at a distance of 12 inches, and a pair with an angle of 15° will occasion coincidence at 8 inches."[1]

The form of stereoscope generally used is that invented by Sir David Brewster, and is known as the refracting stereoscope. The arrangement is shown diagrammatically in fig. 4. Let the left eye be at A and the right at B; let a and b be the corresponding pictures for each eye, and p_1, p_2, two prisms of glass. A prism refracts rays of light so that the object seen through the prism appears to be nearer to the refracting edge; the prism p_1 therefore refracts the ray ap_1 in the direction p_1A, as if it proceeded from c. The prism p_2 refracts the ray bp_2 so that to the eye at B it also appears to proceed from c. The effect of this is that the object really appears to be at c. And as the points a and b combine to form the point c, so d and e unite to form the point f, and g and h to form the point i (Weinhold). This stereoscope consists of a pyramidal box blackened inside and having a lid for the admission of light (fig. 5). At the narrow end of the box are two tubes carrying the lenses. The tubes move up and down to suit eyes of different focal lengths, and sometimes convex or concave lenses are inserted over the prisms to meet the wants of long-sighted or short-sighted persons. Fig. 6 shows the upper end of the stereoscope, with the lenses in position.

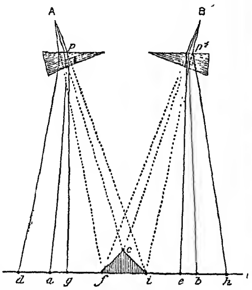

FIG. 4.—Diagram of the Refracting Stereoscope.

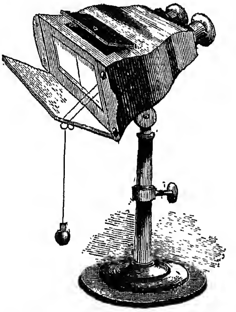

FIG. 5.—Sir David Brewster's Stereoscope.

A. Stroh (without knowing that H. Grubb had described the essentials of the apparatus in 1879) has recently invented a new form of stereoscope based on the well-known effects of the persistence of vision. Two stereoscopic pictures are simultaneously projected by two lanterns on a screen so as to overlap, and disks having suitable slits are rotated in front of the lanterns and also in front of the eyes of the observer, in such a way that only one picture is thrown on the screen at a time, and also that the view of the picture is seen with the right and left eyes alternately. Further, the connexion between the disks is so arranged that the time of obscuring the view of the observer's right eye or left eye coincides with the time when the light is shut off from the right or left lantern, and thus the left eye sees the picture of the left lantern and the right eye that of the right lantern. The two eyes never see at the same time, and each eye views its picture after the other, but the impressions come so fast as to be fused in consciousness, and the result is, the image stands out "in solid relief" (*Proc. Roy. Soc.*, No. 244, vol. xl., April 1, 1886).

FIG. 6.—Lenses in Refracting Stereoscope.

During his researches into the physiology of vision, Wheatstone was led to study what he termed conversions of relief. Sometimes when we look at a geometrical figure such as a cube or rhomboid it may be imagined to represent one of two dissimilar figures. In fig. 7 the rhomboid AX is drawn so that the solid angle A should be seen nearest, and solid angle X farthest, and face ABCD foremost, while XDC is behind. Look steadily and the position will change: X will appear nearest, solid angle A farthest; face ACDB will recede behind XDC.[2] The effects are most obvious when seen with one eye, and "no illusion of this kind can take place when an object of three dimensions is seen with both eyes while the optic axes make a sensible angle with each other, because the appearance of two dissimilar figures, one to each eye, prevents the possibility of mistake" (Wheatstone). The conversion of a cameo into an intaglio and of an intaglio into a cameo is a well-known instance of this illusion. Wheatstone observed the conversion of relief exhibited by binocular pictures in the stereoscope when they are transposed, reflected, or inverted, and this led him to the invention of the *Pseudoscope*, an instrument which conveys to the mind false perceptions of all external objects. "Two rectangular prisms of flint glass, the faces of which are 1·2 inch square, are placed in a frame with their hypothenuses parallel and 2·1 inches from each other; each prism has a motion on an axis corresponding with the angle nearest the eyes, that they may be adjusted so that their bases may have any inclination towards each other" (Wheatstone's *Scientific Papers*, p. 275). In fig. 8 there is a diagram of the instrument. If a spherical surface be examined with this instrument, it will appear hollow; whilst a hollow surface will appear convex. It is remarkable, however, that the converting powers of this instrument are greatest where the new forms can be conceived without effort. Thus a cameo and an intaglio, a plaster cast in relief and its mould, or any object similar in its opposite reliefs is at once changed by the pseudoscope into the converse form. As pointed out by Dr Carpenter, by gazing we can reverse the interior of a mask so as to see the countenance stand out in relief; it is more difficult to throw the features of a bust into the shape of a mould; whilst it is impossible to effect any conversion upon the features of the living face. "The optical change is identically the same in its nature in every one of these cases; and there is nothing in the form of the features which refuses to present a converse, this converted shape being presented by the mask; but the mind, which will admit the conception of the converted form when suggested by the inanimate mask or bust, is steeled by its previous experience against the notion that actual flesh and blood can undergo such a metamorphosis" (Carpenter, *Edinburgh Review*, 1858, p. 460).

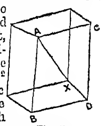

Fig. 7.

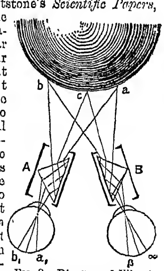

FIG. 8.—Diagram of Wheatstone's Pseudoscope. A, B, tubes containing prisms; a_1, b_1, and α, β, corresponding points; a, b, c, position of points in visual field.

A little consideration will show that the pictures of objects placed at a great distance from the eye are practically if not wholly identical. Here there is scarcely any stereoscopic

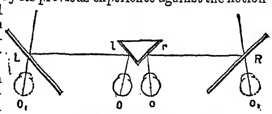

FIG. 9.—Diagram of Von Helmholtz's Telestereoscope.

[1] Wheatstone's *Scientific Papers*, p. 267.

[2] Necker, *Phil. Mag.*, 3d series, vol. i. p. 357.

effect, and the landscape may appear to be flat, as in a picture. To obtain a stereoscopic view of a landscape Von Helmholtz invented the *Telestereoscope*, an instrument which places as it were the point of view of both eyes wide apart. It consists of two mirrors L and R, each of which projects its image upon *l* and *r*, to which the eyes O and *o* are directed. The eyes O and *o* are placed as it were at O_1 and o_1, according to the distance between L and R; consequently two dissimilar pictures are obtained; these are mentally combined, with the result that the landscape is seen like a stereoscopic view.

The principle of the stereoscope was successfully applied by Wenham in 1854 to the construction of the binocular microscope. See MICROSCOPE (vol. xvi. p. 272), and also two papers in the *Journ. Roy. Micr. Soc.*, 1884:—(1) "On the Mode of Vision with Objectives of Wide Aperture," by Prof. E. Abbe, p. 20; and (2) "On the Physiology of Binocular Vision with the Microscope," by Dr Carpenter, p. 486. Prof. Abbe shows, however, that "oblique vision in the microscope is entirely different from that in ordinary vision, inasmuch as there is no perspective, so that we have no longer the dissimilarity which is the basis of the ordinary stereoscopic effect, but an essentially different mode of dissimilarity between the two pictures." In the microscope there is no perspective foreshortening. There is no difference in the outline of an object viewed under the microscope by an axial or by an oblique pencil. There is simply a lateral displacement of the image—an entirely different phenomenon to that which occurs in non-microscopic vision. Thus, whilst the mode of formation of dissimilar pictures in the binocular microscope is different from the production of ordinary stereoscopic pictures, the brain mechanism by which they are so fused as to give rise to sensations of solidity, depth, and perspective is the same. (J. G. M.)

STEREOTYPE. See TYPOGRAPHY.

STERLING, a city of the United States, in Whiteside county, Illinois, on Rock River (a tributary of the Mississippi), 110 miles west of Chicago. Mainly on account of the abundant water-power produced by the natural rapids of the river and a dam 1100 feet long, it has become the seat of the most varied manufacturing industry. An artesian well 1000 feet deep, discharging 18,000 gallons per hour, contributes to the water-supply of the town. The population was 5312 in 1870 and 5087 in 1880. Sterling was laid out in 1836 and incorporated in 1857.

STERLING, JOHN (1806–1844), author, was descended from a family of Scottish origin which had settled in Ireland about the Cromwellian period. His father, Edward Sterling, born at Waterford 27th February 1773, had been called to the Irish bar, but, having fought as a militia captain at Vinegar Hill, afterwards volunteered with his company into the line. On the breaking up of his regiment he went to Scotland, and took to farming at Kames Castle in Bute, where John, the second son, was born 20th July 1806. In 1810 the family removed to Llanblethian, Glamorganshire, and during his residence there Edward Sterling, under the signature of "Vetus," contributed a number of letters to the *Times*, which were reprinted in 1812, and a second series in 1814. In the latter year he removed to Paris, but, the escape of Napoleon from Elba in 1815 compelling him to return to England, he took up his permanent residence in London, obtaining a connexion with the *Times* newspaper, and ultimately being promoted editor. Carlyle, who allows him the dubious credit of being one of the best of newspaper editors, represents him as manifesting "a thoroughly Irish form of character, fire and fervour, vitality of all kinds in genial abundance, but in a much more loquacious, ostentatious, much *louder* style than is freely patronized on this side of the Channel." His fiery, emphatic, and oracular mode of writing conferred those characteristics on the *Times* which were recognized in the sobriquet of the "Thunderer." The frequent changes of the family residence during the early years of young Sterling rendered his education somewhat desultory, but on the settlement in London it became more systematic. After studying for one year at the university of Glasgow, he in 1824 entered Trinity College, Cambridge, where he had for tutor Julius Charles Hare. At Cambridge he did not distinguish himself except in the debates of the union, where, "none," it was related, "ever came near him except the late Charles Buller." He removed to Trinity Hall with the intention of graduating in law, but left the university without taking a degree. During the next four years he resided chiefly in London, employing himself actively in literature. Along with Frederick Maurice he purchased the *Athenæum* from J. Silk Buckingham, but the enterprise was not a pecuniary success. Through Maurice he became an "assiduous pilgrim" to the shrine of Coleridge at Hampstead. He also formed an intimacy with the Spanish revolutionist General Torrijos, in whose unfortunate expedition he took an active interest. Shortly after his marriage in 1830, symptoms of pulmonary disease induced him to take up his residence in the island of St Vincent, where he had inherited some property, but after fifteen months he returned to England. After spending some time on the Continent he found his health so much re-established that in June 1834 he accepted a curacy at Hurstmonceaux, where his old tutor Julius Hare was vicar. Acting on the advice of his physician he resigned his clerical duties in the following February, but according to Carlyle ill-health was only the external occasion of his resignation, the primary cause being a partly unconscious divergence from the opinions of the church. Be this as it may, the threatening progress of the insidious disease under which he laboured soon rendered "public life in any professional form" quite impossible. There remained to him the "resource of the pen," but, having to "live all the rest of his days as in continual flight for his very existence," his literary achievements were necessarily fragmentary, and cannot be regarded as a criterion of his capabilities. He published in 1833 *Arthur Coningsby*, a novel, which attracted little attention, and his *Poems* (1839), the *Election, a Poem* (1841), and *Strafford*, a tragedy, were not more successful. He had, however, established a connexion with *Blackwood's Magazine*, to which he contributed a variety of papers and several tales, which gave promise that under more favourable conditions he might have "achieved greatness." He died at Ventnor 18th September 1844. His father survived him till 1847.

Sterling's papers were entrusted to the joint care of Thomas Carlyle and Archdeacon Hare, and it was agreed that the selection of his writings for publication and the preparation of a memoir should be undertaken by the latter. *Essays and Tales*, by John Sterling, collected and edited, with a memoir of his life, by Julius Charles Hare, appeared therefore in 1848 in two volumes. So dissatisfied was Carlyle with the memoir, chiefly because it unduly magnified the ecclesiastical side of Sterling's life, that he resolved to give his own "testimony" about his friend, and "record clearly" what his "knowledge of him was." His vivid portraiture of Sterling in the *Life* which appeared in 1851 has perpetuated the memory of Sterling after his writings have ceased to be of interest on their own account.

STERNBERG, a manufacturing town in Moravia, Austria, is situated 9 miles to the north of Olmutz and 47 miles to the north-east of Brunn. It is the chief seat of the Moravian cotton industry, and it also carries on the manufacture of linen, stockings, liqueurs, sugar, and bricks. Its six suburbs and the surrounding districts are also engaged in the textile industry. Fruit, especially cherries, and tobacco are grown in the neighbourhood. The population in 1880 was 14,243. Sternberg is said to have grown up under the shelter of a castle founded by Yaroslaff of Sternberg on the site of his victory over the Mongols in 1241.

STERNE, LAURENCE (1713–1768), one of the greatest of English humorists, was the son of an English officer, and great-grandson of an archbishop of York. Nearly all our information about the first forty-six years of his life before he became famous as the author of *Tristram Shandy* is derived from a short memoir jotted down by

himself for the use of his daughter. It gives nothing but the barest facts, excepting three anecdotes about his infancy, his school-days, and his marriage. The date of his birth coincides with the close of the Marlborough wars. He was born at Clonmel, Ireland, on November 24, 1713, a few days after the arrival of his father's regiment from Dunkirk. The regiment was then disbanded, but very soon after re established, and for ten years the boy and his mother moved from place to place after the regiment, from England to Ireland, and from one part of Ireland to another. The familiarity thus acquired with military life and character stood Sterne in good stead when he drew the portraits of Uncle Toby and Corporal Trim, and the influence of the excitements, shifts, and hardships of this life of vagabond gentility may also be traced in his own character. To its hardening effect we may fairly refer some part of his later reckless defiance of clerical proprieties and comical persistence in self-conscious eccentricity. After ten years of wandering, he was fixed for eight or nine years at a school near Halifax in Yorkshire. His father died when he was in his eighteenth year, and he was indebted for his university education to one of the members of his father's family. His great grandfather the archbishop had been master of Jesus College, Cambridge, and to Jesus College he was sent in 1732. He was admitted to a sizarship in July 1733, and took his B.A. degree in 1736. One of his uncles was a prominent church dignitary in Yorkshire. Young Sterne took orders, and through his influence obtained in 1738 the living of Sutton, some 8 miles north of York. On his marriage three years afterwards he was presented to the neighbouring living of Stillington, and did duty at both places. He was also a prebendary of York.

Sutton was Sterne's residence for twenty uneventful years—years at least concerning which his biography is silent. The only ascertained fact of consequence is that he kept up an intimacy which had begun at Cambridge with John Hall Stevenson, a witty and accomplished epicurean, owner of Skelton Castle in the Cleveland district of Yorkshire. Skelton Castle is nearly 40 miles from Sutton, but Sterne, in spite of his double duties, seems to have been a frequent visitor there, and to have found in his not too strait laced friend a highly congenial companion. Stevenson's various occasional sallies in verse and prose—his *Fables for Grown Gentlemen*, his *Crazy Tales*, and his numerous skits at the political opponents of Wilkes, among whose "macaronies" he numbered himself,—were collected after his death, and it is impossible to read them without being struck with their close family resemblance in spirit and turn of thought to Sterne's work, inferior as they are in literary genius. Without Stevenson Sterne would probably have been a more decorous parish priest, but he would probably never have written *Tristram Shandy* or left any other memorial of his singular genius. The two friends began to publish late in life and in the same year. The first two volumes of *Tristram Shandy* were issued on the 1st of January 1760, and at once made a sensation. York was scandalized at its clergyman's indecency and indignant at his caricature of a local physician; London was charmed with his audacity, wit, and graphic unconventional power. He went to London early in the year to enjoy his triumph, and found himself at once a personage in society,—was called upon and invited out by lion-hunters, was taken to Windsor by Lord Rockingham, and had the honour of supping with the duke of York.

For the last eight years of his life after this sudden leap out of obscurity we have a faithful record of Sterne's feelings and movements in letters to various persons, published after his death by his daughter. At the end of the famous Sermon on Conscience in vol. ii. of *Tristram* he had intimated that, if this sample of Yorick's pulpit eloquence was liked, "there are now in the possession of the Shandy family as many as will make a handsome volume at the world's service—and much good may they do it." Accordingly, when a second edition of the first instalment of *Tristram* was called for in three months, two volumes of *Sermons* by Yorick were announced. Although they had little or none of the eccentricity of the history, they proved almost as popular. Sterne's clerical character was far from being universally injured by his indecorous freaks as a humorist. Lord Faulconberg presented the author of *Tristram Shandy* with the living of Coxwold. To this new residence he went in high spirits with his success, "fully determined to write as hard as could be," seeing no reason why he should not give the public two volumes of Shandyism every year and why this should not go on for forty years. By the beginning of August he had another volume written, and was "so delighted with Uncle Toby's imaginary character that he was become an enthusiast." The author's delight in this wonderful creation was not misleading; it has been fully shared by every generation of readers since. For two years in succession Sterne kept his bargain with himself to produce two volumes a year. Vols. iii. and iv. appeared in December 1760, vols. v. and vi. in January 1762. But his sanguine hopes of continuing at this rate were frustrated by ill-health. He was ordered to the south of France; it was two years and a half before he returned; and he came back with very little accession of strength. His reception by literary circles in France was very flattering. He was overjoyed with it. "'Tis *comme à Londres*," he wrote to Garrick from Paris; "I have just now a fortnight's dinners and suppers upon my hands." And again, "Be it known I Shandy it away fifty times more than I was ever wont—talk more nonsense than ever you heard me talk in your days, and to all sorts of people." Through all his pleasant experiences of French society, and through the fits of dangerous illness by which they were diversified, he continued to build up his history of the Shandy family, but the work did not progress as rapidly as it had done. Not till January 1765 was he ready with the fourth instalment of two volumes; and one of them, vol. vii., leaving the Shandy family for a time, gave a lively sketch of the writer's own travels to the south of France in search of health. This was a digression of a new kind, if anything can be called a digression in a work the plan of which is to fly off at a tangent whenever and wherever the writer's whim tempts him. In the first volume, anticipating an obvious complaint, he had protested against digressions that left the main work to stand still, and had boasted—not without justice in a Shandean sense—that he had reconciled digressive motion with progressive. But in vol. vii. the work is allowed to stand still while the writer is being transported from Shandy Hall to Languedoc. The only progress we make is in the illustration of the buoyant and joyous temper of Tristram himself, who, after all, is a member of the Shandy family, and was due a volume for the elucidation of his character. Vol. viii. begins the long-promised story of Uncle Toby's amours with the widow Wadman. After seeing to the publication of this instalment of *Tristram* and of another set of sermons,—more pronouncedly Shandean in their eccentricity,—he quitted England again in the summer of 1765, and travelled in Italy as far as Naples. The ninth and last and shortest volume of *Tristram*, concluding the episode of Toby Shandy's amours, appeared in 1767. This despatched, Sterne turned to a new project, which had probably been suggested by the ease and freedom with which he had moved through the travelling volume in

Tristram The *Sentimental Journey through France and Italy* was intended to be a long work the plan admitted of any length that the author chose, but, after seeing the first two volumes through the press in the early months of 1768, Sterne's strength failed him, and he died in his London lodgings on the 18th of March, three weeks after the publication The loneliness of his end has often been commented on, it was probably due to its unexpectedness He had pulled through so many sharp attacks of his "vile influenza" and other lung disorders that he began to be seriously alarmed only three days before his death

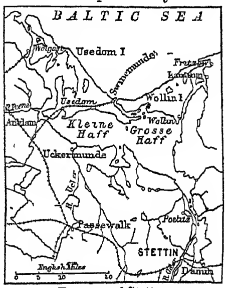
Sterne's character defies analysis in brief space It is too subtle and individual to be conveyed in general terms For comments upon him from points of view more or less diverse the reader may be referred to Thackeray's *Humourists*, Prof Masson's *Novelists*, and Mr H D Traill's sketch in the "English Men of Letters" series The fullest biography is Mr Percy Fitzgerald's But the reader who cares to have an opinion about Sterne should hesitate till he has read and re-read in various moods considerable portions of Sterne's own writing This writing is so singularly frank and unconventional that its drift is not at once apparent to the literary student The indefensible indecency and overstrained sentimentality are on the surface, but after a time every repellent defect is forgotten in the enjoyment of the exquisite literary art In the delineation of character by graphically significant speech and action, introduced at unexpected turns, left with happy audacity to point their own meaning, and pointing it with a force that the dullest cannot but understand, he takes rank with the very greatest masters In Toby Shandy he has drawn a character universally lovable and admirable, but Walter Shandy is almost greater as an artistic triumph, considering the difficulty of the achievement Dr Ferriar, in his *Illustrations of Sterne* (published in 1812), pointed out several unacknowledged plagiarisms from Rabelais, Burton, and others, but it is only fair to the critic to say that he was fully aware that they were only plagiarisms of material, and do not detract in the slightest from Sterne's reputation as one of the greatest of literary artists (W M)

STESICHORUS of Himera, a very famous lyric poet, lived between 630 and 550 B C His name was originally Tisias, if we may trust Suidas, but it was changed to Stesichorus on account of his eminence in choral poetry He was famed in antiquity for the richness and splendour of his imagination and his style, although Quintilian censures his redundancy and Hermogenes remarks on the excessive sweetness that results from his abundant use of epithets We are told that he warned his fellow citizens against Phalaris, whom they had chosen as their general, by relating to them the well-known fable of the horse and the stag The story that he was struck blind for slandering Helen in a poem, and afterwards recovered his sight when he had sung a recantation, is told first by Plato, and afterwards, with many additions, by Pausanias and others We possess some fragments of the former poem, censuring the daughters of Tyndareus, who "wed two, nay three husbands, and leave their lords" (Fr 26), and three lines from the palinode, "This is no true tale, nor yet wentest thou in the strong benched ships, or camest to the tower of Troy" (Fr 32) It seems probable that Stesichorus did really write his recantation in consequence of a dream which he had soon after composing his poem on Helen, and his is not the only case in literature where an apparently miraculous cure is said to have followed some such act of atonement We possess about thirty fragments of his poems, not counting single words, preserved in Athenæus and elsewhere None of them is longer than six lines They are written in the Doric dialect, with epic licences and occasional Æolisms, the metre is dactylico-trochaic Brief as they are, they show us what Longinus meant by calling Stesichorus "most like Homer", they are full of epic grandeur, and have a stately sublimity that reminds us of Pindar Stesichorus indeed made a new departure by using lyric poetry to celebrate gods and heroes rather than human feelings and passions, this is what Quintilian means by saying that he "sustained the burden of epic poetry with the lyre" Several of his poems sung of the adventures of Heracles, one dealt with the siege of Thebes, another with the sack of Troy The last—to which the *Tabula Iliaca* (see Otto Jahn's *Griechische Bilderchroniken*, ed A Michaelis) is a sort of commentary—possesses an interest for us as the first poem in which occurred that form of the story of Æneas's flight to which Virgil afterwards gave currency in his *Æneid* Stesichorus also completed the choral ode by adding to the strophe and antistrophe the epode, and not to know "Stesichorus's three" passed into a proverbial expression for unpardonable ignorance

Bergk, *Poetæ Lyrici Græci*, vol iii pp 205-234, Leipsic, 1882

STETHOSCOPE See AUSCULTATION

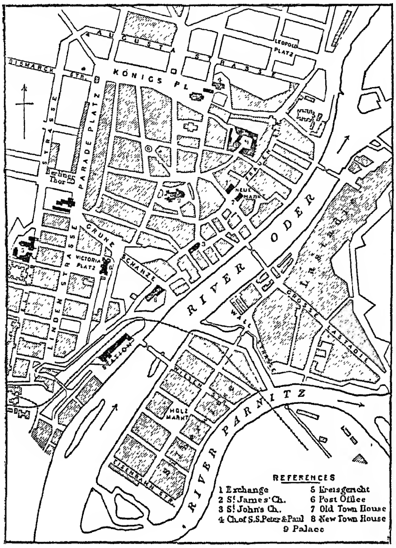
STETTIN, the chief town of Pomerania, and the leading seaport in Prussia, is situated on the Oder, 17 miles to the south of the Stettiner Haff and 30 miles from the Baltic Sea The main part of the town occupies a hilly site on the left bank of the river, and is connected by four bridges (including a massive railway swing-bridge) with the suburbs of Lastadie ("lading place," from *lastadium*, "burden,") and Silberwiese, on an island formed by the Parnitz and Dunzig, which here diverge from the Oder to Dammsche-See Until 1874 Stettin was closely girdled by very extensive and strong fortifications, which prevented the expansion of the town proper, but the steady growth of its commerce and manufactures encouraged the foundation of numerous industrial suburbs beyond the line of defence Some of these are themselves "towns," as Grabow, with 13,672 inhabitants in 1880, and Bredow with 11,255 inhabitants, but all combine with Stettin to form one industrial and commercial centre Since the removal of the fortifications their site has begun to be built upon Apart from its commerce, Stettin is a comparatively uninteresting city The church of Sts Peter and Paul, originally founded in 1124 and restored in 1816–17, was the earliest Christian church in Pomerania St James's church, dating from the 13th and the two following centuries, is remarkable, like several other Pomeranian churches, for its size The old palace, now occupied by Government offices, is a large unattractive edifice, scarcely justifying the boast of an old writer that it did not yield in magnificence even to the palaces of Italy Among the more modern structures are the theatre and the new town-house, superseding an earlier one of 1245 Statues of Frederick the Great and of Frederick William III. adorn one of the five open squares of the old town As a prosperous commercial town Stettin has numerous educational, benevolent, and scientific institutions



Environs of Stettin

The manufactures are very important, many of the largest factories are in the neighbouring villages, beyond Stettin proper. The shipbuilding yards (among which

that of the Vulcan Company deserves mention) have comparatively recently attained some reputation for their ironclads and war-vessels. Machinery, cement, chemicals, and soap are produced in large quantities, and there are also



Plan of Stettin.

large sugar-refineries, besides a vast miscellany of other smaller industrial establishments. The trade of Stettin is very flourishing. More than any other harbour it may be regarded as the port of Berlin, from which it is 93 miles north-east by railway; and a larger number of vessels enter and clear at Stettin than at any other German port except Hamburg and Bremerhaven. SWINEMÜNDE (*q.v.*) serves as its fore-port. The forest and river scenery of the neighbourhood of Stettin is picturesque, but the low level and swampy nature of the soil render the climate bleak and unhealthy. In 1885 the population was 99,475; in 1880 it was 91,756, of whom 85,727 were Protestants, 3112 Roman Catholics, and 2388 Jews.

In 1885 3809 ocean vessels (2207 steamers) and 1965 coasting and river craft, besides 10,039 Oder barges, entered the port. In 1885 Stettin possessed (besides a large number of river craft) a fleet of 127 sea-going ships, with a burden of 47,066 tons, of which 26,754 tons were distributed in 59 steamers. The chief exports are grain, spirits, and wood; the chief imports petroleum, train-oil, wine, and herrings. The annual value of the former is about £7,500,000 and of the latter about £6,000,000.

Stettin is said to have existed as a Wendish fishing-village as early as 830 A.D., and it appears as Stedyn in the time of the Saxon emperors. From the 12th century it was the seat of the dukes of Pomerania, who became extinct in 1637. Passing then to Sweden, it remained united with that kingdom for eighty-three years, with one brief interval, but in 1720 it was ceded to Prussia. Gustavus Adolphus undertook to improve its fortifications in 1630, but Frederick the Great was the first to convert it into a strong modern fortress. From 1806 till 1813 it was held by the French, to whom it was surrendered without a blow. Known even in the 12th century as the leading trading-town on the Oder, Stettin entered the Hanseatic League in 1360. The development of its trade in modern times dates chiefly from the deepening and protection of the Swine in the former half of last century. See ODER.

STEUART, SIR JAMES DENHAM (1712–1780), BART., author of *An Inquiry into the Principles of Political Economy* (see POLITICAL ECONOMY, vol. xix. p. 365), was the only son of Sir James Steuart, solicitor-general for Scotland under Queen Anne and George I., and was born at Edinburgh on October 21, 1712. After passing through the university of Edinburgh he was admitted to the Scottish bar at the age of twenty-four. He then spent some years on the Continent, and while in Rome entered into relations with the Pretender. He was in Edinburgh in 1745, and so compromised himself that after the battle of Culloden he found it necessary to return to the Continent, where he remained until 1763. It was not indeed until 1771 he was fully pardoned for any complicity he may have had in the rebellion. He died at his family seat, Coltness, in Lanarkshire, on November 26, 1780.

The Works, Political, Metaphysical, and Chronological, of the late Sir James Steuart of Coltness, Bart., now first collected, with Anecdotes of the Author, by his Son, General Sir James Denham Steuart, were published in 6 vols. 8vo in 1805. Besides the *Inquiry* (originally published in 2 vols. 4to in 1767), they include—*A Dissertation upon the Doctrines and Principles of Money applied to the German Coin* (1758), *Apologie du Sentiment de M. le Chevalier Newton sur l'Ancienne Chronologie des Grecs* (4to, Frankfort-on-the-Main, 1757), *The Principles of Money applied to the Present State of Bengal*, published at the request of the East India Company (4to, 1772), *A Dissertation on the Policy of Grain* (1783), *Plan for Introducing Uniformity in Weights and Measures within the Limits of the British Empire* (1790), *Observations* on Beattie's *Essay on Truth*, *A Dissertation concerning the Motive of Obedience to the Law of God*, and other treatises.

STEUBENVILLE, a city of the United States, county seat of Jefferson county, Ohio, lies 43 miles west of Pittsburgh, on the west bank of the Ohio river, here a third of a mile wide and crossed by a railway bridge. Built above a productive coalfield, and with an abundant supply of natural gas for fuel purposes, Steubenville has naturally become a manufacturing centre (foundries, rolling-mills, nail and glass factories, potteries, machine-shops, flour-mills, &c.), and as the surrounding district is a good farming, wool-growing, and stock-raising country it is the seat of considerable commercial activity. The court-house is a particularly fine building. In 1870 the population was 8107, in 1880 12,093. Steubenville, so called after Baron Steuben, one of Washington's generals, grew up round a fort erected in 1787. It became a city in 1851.

STEVENS, ALFRED. See SCULPTURE, vol. xxi. p. 561.

STEVENS, THADDEUS (1792–1868), was born at Peacham, Vermont, U.S., April 4, 1792, graduated at Dartmouth College in 1814, and then settled in Pennsylvania. He soon became a leading lawyer of Lancaster, Pa., so far interested in politics as to be elected by the Whig party to the State legislature for several terms and to the federal house of representatives 1849–63. When the mass of the Northern Whig party went into the new Republican party he went with it, and returned to Washington as a Republican representative in 1859, just before the outbreak of the Civil War. This position he retained until his death, just outlasting the Civil War and reconstruction. During this period of American history he was one of the leading characters. The methods on which he proposed to conduct the war were always drastic: the wholesale confiscation of lands in the seceding States, the disfranchisement of insurgent citizens, the emancipation and enfranchisement of the negroes, all found in him their earliest and warmest advocate. While other parties and leaders were continually shifting their ground, changing their theories of the relations of the Union to the seceding States as the struggle grew more intense, Stevens was consistent from beginning to end. The almost universal theory was that the war was prosecuted only to enforce the constitution; it was therefore incumbent on those who prosecuted it to obey the constitution punctiliously, how-

ever puzzling might be the difficulties into which it led them. Stevens, on the contrary, insisted that armed resistance to the constitution had the effect of suspending the constitution within the area of the resistance; that the success of the resistance would show whether the suspension was to be temporary or permanent; and that, in the meantime, those who resisted the constitution were entitled to no rights under it,—in fact, to no rights except those reserved under the laws of war. This was too radical even for the war party; but, at the end of the war, Stevens's pronounced ability gave him the leadership of the house committee on reconstruction. Even in this position, he never obtained a formal endorsement of his theory; but the practical management of reconstruction shows its strong influence in many features otherwise inexplicable. He lived to take a leading part in the unsuccessful impeachment of President Johnson, and to see the admission of the first instalment of reconstructed States, and died at Washington, August 11, 1868.

Stevens's life has been written from a friendly and from a hostile point of view,—the former in the volume entitled *Thaddeus Stevens, Commoner*, the latter in Harris's *Political Conflict in America*.

STEVENSON, Robert (1772–1850), civil engineer, was the only son of Alan Stevenson, partner in a West Indian house in Glasgow, and was born in that city 8th June 1772. Having lost his father in infancy, he removed with his mother to Edinburgh. In his youth he assisted his step-father, Thomas Smith, in his lighthouse schemes, and at the early age of nineteen was sent to superintend the erection of a lighthouse on the island of Little Cumbrae. During successive winters he attended classes at Anderson's College, Glasgow, and at Edinburgh university. He succeeded his stepfather, whose daughter he married in 1799, as engineer to the Board of Northern Lighthouses, and at the same time began general practice as a civil engineer. During his period of office from 1797 to 1843, he designed and executed no fewer than eighteen lighthouses, the most important being that on the Bell Rock, begun in 1807 and completed in 1810, in which he improved considerably on the designs of Smeaton for the Eddystone lighthouse (see Lighthouse, vol. xiv. p. 616). For its illumination he introduced an improved apparatus; he was also the author of various other valuable inventions in connexion with lighting, including the intermittent and flashing lights, and the mast lantern for ships. In his general practice as a civil engineer he was employed in the construction of many county roads, in various important improvements in connexion with the approaches to Edinburgh, including that by the Calton Hill, in the erection of slips at ferries, in the construction of harbours, docks, and breakwaters, in the improvement of river and canal navigation, and in the construction of several important bridges. It was he that brought into notice the superiority of malleable iron rods for railways over the old cast iron, and he was the inventor of the movable jib and balance cranes. It was chiefly through his interposition that an Admiralty survey was established, from which the Admiralty sailing directions for the coasts of Great Britain and Ireland have been prepared. Stevenson was elected a fellow of the Royal Society of Edinburgh in 1815, and afterwards became a member of the Geological and Astronomical Societies of London and the Wernerian and Antiquarian Societies of Scotland. He published an account of the Bell Rock lighthouse in 1824, and, besides contributing important articles on engineering subjects to Brewster's *Edinburgh Encyclopædia* and the *Encyclopædia Britannica*, was the author of various papers read before the societies he was connected with. He died at Edinburgh 12th July 1850.

A *Life of Robert Stevenson*, by his son David Stevenson, appeared in 1878. David Stevenson (1815–86), who along with his brother Alan succeeded to his father's business, was the author of a *Sketch of the Civil Engineering of North America* (1838, republished in "Weale's Series," 1859), *Marine Surveying* (1842), *Canal and River Engineering* (1858, 2d ed. enlarged, 1872, 3d ed. 1886), and of various papers read before learned societies.

STEVINUS, Simon (1548–1620). This great mathematician was born in 1548 at Bruges (where the Place Simon Stevin contains his statue by Eugen Simonis) and died in 1620 at The Hague or in Leyden. Of the circumstances of his life very little is recorded; the exact day of his birth and the day and place of his death are alike uncertain. It is known that he left a widow with two children; and one or two hints scattered throughout his works inform us that he began life as a merchant's clerk in Antwerp, that he travelled in Poland, Denmark, and other parts of northern Europe, and that he was intimate with Prince Maurice of Orange, who asked his advice on many occasions, and made him a public officer,—at first director of the so-called "waterstaet," and afterwards quartermaster-general. The question whether Stevinus, like most of the rest of the prince's followers, belonged to the Protestant creed hardly admits of a categorical answer. A Catholic, it may be said, would never in those times have risen to so high a position. A Catholic would perhaps not have been so ready as Stevinus to deny the value of all authority, whether of an Aristotle, of an Euclid, or of a Vitruvius. A Catholic could not well have boasted, as Stevinus in a political pamphlet did, that he had always been in harmony with the executive power. But against these considerations it might be urged that a Protestant had no occasion to boast of a harmony most natural to him, while his further remark, in the same pamphlet, to the effect that a state church is indispensable, and that those who cannot belong to it on conscientious grounds ought to leave the country rather than show any opposition to its rites, seems rather to indicate the crypto-Catholic, who wishes for reasons of his own to remain in the Netherlands. The same conclusion is supported by the ascertained fact that Stevinus, a year before his death, bequeathed a pious legacy to the church of Westkerke in Flanders, out of the revenues of which masses were to be said. But, however it may be answered, the question is fortunately of little importance to us, as Stevinus was neither a political personage nor did he engage in religious controversy. He was mainly, as already said, a great mathematician, and it is chiefly in this quality that we must try to get acquainted with him. His claims to fame are most varied. Some of them appealed strongly to the men of his time, but many were such as could not well be understood by most of his contemporaries, and have found due acknowledgment only in later times.

His contemporaries were most struck by his invention of a carriage with sails, a little model of which was preserved at Scheveningen till 1802. The carriage itself had been lost long before; but we know that about the year 1600 Stevinus, with Prince Maurice of Orange and twenty-six others, made use of it on the sea-shore between Scheveningen and Petten, that it was propelled solely by the force of the wind, and that it acquired a speed which exceeded that of horses. Another idea of Stevinus, for which even Grotius gave him great credit, was his notion of a bygone age of wisdom. Mankind once knew everything knowable, but gradually forgot most of it, till a time came when little by little the forgotten knowledge was reacquired; the goal to be aimed at is the bringing about of a second age of wisdom, in which mankind shall have recovered all its early knowledge. The fellow-countrymen of Stevinus were proud that he wrote in their own dialect, which he thought fitted for a universal language, as no other abounded like Dutch in monosyllabic radical words.

History has been much less enthusiastic than his con-

temporaries in admiring these claims to fame, but it has discovered in Stevinus's works various inventions which did not at once receive the notice they deserved. He was the first to show how to fashion regular and semiregular polyhedra by delineating their frames in a plane. Stevinus also distinguished stable from unstable equilibrium. He proved the law of the equilibrium on an inclined plane. He demonstrated before Varignon the resolution of forces, which, simple consequence of the law of their composition though it is, had not been previously remarked. He discovered the hydrostatic paradox that the downward pressure of a liquid is independent of the shape of the vessel, and depends only on its height and base. He also gave the measure of the pressure on any given portion of the side of a vessel. He had the idea of explaining the tides by the attraction of the moon.

It remains to enumerate those claims of Stevinus to immortality which were recognized from the first and which succeeding ages have not lessened,—his writings on military science, on book-keeping, and on decimal fractions.

That the man who was quartermaster-general to Maurice of Orange should have been possessed of more than ordinary merit, and have left behind him military papers of lasting value, is hardly more than might have been expected. This expectation, in the case of Stevinus at least, is fully borne out in the opinion of competent judges. Prince Maurice is known as the man who conquered the greatest number of fortresses in the shortest time, and fortification was the principal aim of his adviser. Stevinus seems to be the first who made it an axiom that strongholds are only to be defended by artillery, the defence before his time having relied mostly on small firearms. He wrote upon temporary fortifications, but the excellence of his system was only slowly discerned. He was the inventor of defence by a system of sluices, which proved of the highest importance for the Netherlands. His plea for the teaching of the science of fortification in universities, and the existence of such lectures in Leyden, have led to the impression that he himself filled this chair; but the belief is quite erroneous, as Stevinus, though living at Leyden, never had direct relations with its university.

Book-keeping by double entry may have been known to Stevinus as clerk at Antwerp either practically or through the medium of the works of Italian authors like Paccioli and Cardan. He, however, was the first to recommend the use of impersonal accounts in the national household. He practised it for Maurice, and recommended it in a small pamphlet to Sully the French statesman; and, if public book-keeping has grown more and more lucid by the introduction of impersonal accounts, it is certainly to Stevinus that the credit of the improvement is due.

His greatest success, however, was a small pamphlet, first published in Dutch in 1586, and not exceeding seven pages in the French translation (which alone we have seen). This translation is entitled *La Disme, enseignant facilement expédier par Nombres Entiers sans rompuz, tous Comptes se rencontrans aux Affaires des Hommes.* Decimal fractions had been employed for the extraction of square roots some five centuries before his time, but nobody before Stevinus established their daily use; and so well aware was he of the importance of his innovation that he declared the universal introduction of decimal coinage, measures, and weights to be only a question of time. His notation is rather unwieldy. The point separating the integers from the decimal fractions seems to be the invention of Bartholomæus Pitiscus, in whose trigonometrical tables (1612) we have found it, and it was accepted by Napier in his logarithmic papers (1614 and 1619). Stevinus printed little circles round the exponents of the different powers of one-tenth. For instance, $237\frac{578}{1000}$ was printed 237 ⓪ 5 ① 7 ② 8 ③, and the fact that Stevinus meant those encircled numerals to denote mere exponents is evident from his employing the very same sign for powers of algebraic quantities, *e.g.*, 9 ④ − 14 ③ + 6 ① − 5 to denote $9x^4 - 14x^3 + 6x - 5$. He does not even avoid fractional exponents ("Racine cubique de ② serait $\frac{2}{3}$ en circle"), and is ignorant only of negative exponents. Powers and exponents have also been carried back to a period several centuries earlier than Stevinus, and it is not here intended to give him any undue credit for having maintained them; but we believe it ought to be recognized more than it generally is, that for our author there was a connexion between algebraic powers and decimal fractions, and that even here Stevinus the profound theorist is not lost to view behind Stevinus the man of brilliant practical talents. (M. CA.)

STEWART, or STUART. For the royal house of this name, see STUART.

STEWART, DUGALD (1753–1828), one of the most influential of the Scottish philosophers, was born at Edinburgh on the 22d of November 1753. His father, Matthew Stewart (1715–85), was professor of mathematics in the university of Edinburgh from 1747 till 1772, and was an eminent investigator in his own department, applying the geometrical methods of Simson, who had been his teacher in Glasgow. Dugald Stewart's early years were passed partly in Edinburgh and partly at Catrine in Ayrshire, where his father had a small property, to which the family removed every summer on the close of the academical session. Burns was an occasional visitor at Catrine, which is only a few miles from Mossgiel; and the philosopher and the poet had various meetings as well as some slight correspondence in later years. Dugald Stewart was educated at the high school and university of his native town. At school he laid the foundation of the classical knowledge and literary taste which are conspicuous in his works, and which lent a charm to his prelections. At the university his chief subjects were the mathematical sciences—in which he attained great proficiency—and philosophy. Adam Ferguson, the historian of the Roman republic, was then professor of moral philosophy in Edinburgh, and his bracing ideal of ethical and political virtue commended itself highly to Stewart. In 1771, having thoughts of entering the English Church, Stewart proceeded to Glasgow with a view to the Snell exhibitions tenable by Glasgow students at Oxford. Here he listened to the lectures of Reid, whose *Inquiry*, published seven years before, had laid the effective foundation of what is called distinctively the Scottish philosophy. Reid became Stewart's acknowledged master and also his friend, while Stewart's academic eloquence and powers of elegant exposition gained for their common doctrines a much wider acceptance than they could have secured in the clumsier and less attractive presentation of Reid himself. In Glasgow Stewart boarded in the same house with Archibald Alison, afterwards author of the *Essay on Taste*, and a close friendship sprang up between them, which remained unbroken through life. After no more than a single session in Glasgow, Dugald Stewart was summoned by his father, whose health was beginning to fail, to conduct the mathematical classes in the university of Edinburgh. Though only nineteen years of age he discharged his duties with marked ability and success; and after acting three years as his father's substitute he was elected professor of mathematics in conjunction with him in 1775. Three years later Adam Ferguson was appointed secretary to the commissioners sent out to the American colonies, and at his urgent request

Stewart lectured as his substitute. Thus during the session 1778-79, in addition to his mathematical work, he delivered an original course of lectures on morals. "To this season," says his son, "he always referred as the most laborious of his life; and such was the exhaustion of the body from the intense and continued stretch of the mind that on his departure for London at the close of the academical session it was necessary to lift him into the carriage." In 1783 Stewart married Helen Bannatyne, who died in 1787, leaving an only son, Colonel Matthew Stewart, from whose short memoir of his father the above is a quotation.

In 1785, on the resignation of Ferguson, he was transferred to the chair of moral philosophy, which he filled for a quarter of a century and made a notable centre of intellectual and moral influence. Young men of rank and of parts were attracted by his reputation from England, and even from the Continent and America. A very large number of men who afterwards rose to eminence in literature or in the service of the state were thus among his students. Sir Walter Scott, Jeffrey, Cockburn, Francis Horner, Sydney Smith, Lord Brougham, Dr Thomas Brown, James Mill, Sir James Mackintosh, and Sir Archibald Alison may be mentioned among others. There is a unanimous testimony to the attractive eloquence of Stewart's lectures and the moral elevation of his teaching. "Dugald Stewart," says Lord Cockburn, "was one of the greatest of didactic orators. Had he lived in ancient times, his memory would have descended to us as that of one of the finest of the old eloquent sages. No intelligent pupil of his ever ceased to respect philosophy, or was ever false to his principles, without feeling the crime aggravated by the recollection of the morality that Stewart had taught him." Dr John Thomson, afterwards medical professor in Edinburgh, was accustomed to say that the two things by which he had been most impressed in the course of his life were the acting of Mrs Siddons and the oratory of Dugald Stewart. Lord Cockburn, in his *Memorials*, has left an interesting portraiture of Stewart's appearance and manner:—"Stewart was about the middle size, weakly-limbed, and with an appearance of feebleness which gave an air of delicacy to his gait and structure. His forehead was large and bald, his eyebrows bushy, his eyes grey and intelligent, and capable of conveying any emotion from indignation to pity, from serene sense to hearty humour, in which they were powerfully aided by his lips, which, though rather large perhaps, were flexible and expressive. The voice was singularly pleasing; and, as he managed it, a slight burr only made its tones softer. His ear, both for music and for speech, was exquisite; and he was the finest reader I have ever heard. His gesture was simple and elegant, though not free from a tinge of professional formality; and his whole manner was that of an academical gentleman, ... calm and expository, but rising into greatness or softening into tenderness whenever his subject required it." The course on moral philosophy embraced, besides ethics proper, lectures on political philosophy or the theory of government, and from 1800 onwards a separate course of lectures was delivered on political economy. These last were extremely important in spreading a knowledge of the fundamental principles of the science at a time when they were still almost unknown to the general public. Stewart's enlightened political teaching was sufficient, in the times of reaction succeeding the French Revolution, to draw upon him the undeserved suspicion of disaffection to the constitution.

In 1790 Stewart married a second time. Miss Cranstoun, who became his wife, was a lady of birth and accomplishments, and he was in the habit of submitting to her criticism whatever he wrote. A son and a daughter were the issue of this marriage. The death of the former in 1809 was a severe blow to the failing health of his father, and was the immediate cause of his retirement from the active duties of his chair. Before that, however, Stewart had not been idle as an author. In 1792 he published the first volume of the *Elements of the Philosophy of the Human Mind*; the second volume appeared in 1814, and the third not till 1827. In 1793 he printed a text-book, *Outlines of Moral Philosophy*, which went through many editions; and in the same year he read before the Royal Society of Edinburgh his account of the *Life and Writings of Adam Smith*. Similar memoirs of Robertson the historian and of Reid were afterwards read before the same body and appear in his published works. In 1805 Stewart took an active part in what was known as the Leslie case, that is to say, the public controversy arising out of the appointment of Mr (afterwards Sir John) Leslie to the chair of mathematics in the university of Edinburgh. Leslie was attacked by the presbytery of Edinburgh, ostensibly on account of his views on the nature of causal connexion, which were said to approximate to Hume's. In two pamphlets Stewart defended Leslie's doctrine as philosophically tenable and theologically innocuous. In 1806 he received in lieu of a pension the nominal office of the writership of the *Edinburgh Gazette*, with a salary of £300. When the shock of his son's death incapacitated him from lecturing during the session of 1809-10, his place was taken, at his own request, by Dr Thomas Brown, who in 1810 was appointed conjoint professor. On the death of Brown in 1820, Stewart, who had taken no further active part in lecturing, retired altogether from the professorship, which was conferred upon John Wilson, better known as "Christopher North." From 1809 onwards Stewart lived mainly at Kinneil House, Linlithgowshire, which was placed at his disposal by the duke of Hamilton. From this retirement he continued to send forth a succession of works. In 1810 appeared *Philosophical Essays*, in 1814 the second volume of the *Elements*, in 1815 the first part and in 1821 the second part of the "Dissertation" written for the *Encyclopædia Britannica* "Supplement," entitled "A General View of the Progress of Metaphysical, Ethical, and Political Philosophy since the Revival of Letters." In 1822 he was struck with paralysis, but recovered a fair degree of health, sufficient to enable him to resume his studies. In 1827 he published the third volume of the *Elements*, and in 1828, a few weeks before his death, *The Philosophy of the Active and Moral Powers*. He died in Edinburgh after a short illness on the 11th of June 1828. A monument to his memory was erected on the Calton Hill by his friends and admirers.

An edition of his *Collected Works*, in eleven volumes (1854-58), was edited by Sir William Hamilton, on whose death in 1856 it was carried to completion and furnished with a memoir of Stewart by Prof. Veitch. Stewart was an elegant writer rather than a profound or original thinker, and he cannot be said to have added much to the philosophy of Reid (see REID), though he contributed very largely to its dissemination. His psychological observations, however, are acute and varied, and his general powers of mind contributed largely to elevate the study of philosophy in the United Kingdom. His reputation rests more upon the tradition of his inspiring and elevating eloquence than upon any definite achievements within the province of philosophy proper. (A. SE.)

STEYR, STEIER, or STEYER, an industrial town in Upper Austria, is situated on an island at the junction of the Steyr and Enns, 20 miles to the south of Linz and 92 miles to the west-south-west of Vienna. The main town is connected by two bridges with the suburbs of Steyrdorf and Ennsdorf. The Gothic parish church was built in 1443; the town-house is modern. The interesting old castle of the princes of Lamberg, dating from the 10th century, rises on an eminence near the town. Steyr

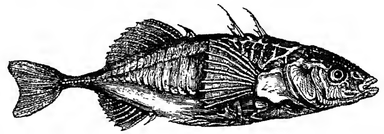
is one of the chief seats of the iron and steel industry in Upper Austria (AUSTRIA, vol. iii. p. 120), and very large quantities of cutlery, scythes, sickles, and edge-tools are annually produced in the town and neighbourhood. The Werndl small-arms factory, now carried on by a joint-stock company, and employing 4500 hands, is the largest in Austria. The population in 1880 was 17,199. Steyr was the capital of an early countship or grafschaft, at first belonging to Styria, but annexed to Austria in 1192.

STICKLEBACK is the name applied to a group of small fishes (*Gastrosteus*) which inhabit the fresh and brackish waters as well as the coasts of the temperate zone of the northern hemisphere. Although some of the species live chiefly either in fresh or in salt water, they readily accommodate themselves to a change, and, as far as the European kinds are concerned, all may be met with in the brackish water of certain littoral districts. The majority have a compressed well-proportioned body, which in the marine species is of a more elongate form, leading to the allied group of Flute-Mouths (*Fistulariidæ*), which are, in fact, gigantic marine sticklebacks. Their mouth is of moderate width, oblique, and armed with small but firmly set teeth. But their most distinctive characteristic consists in the armature of their head and body. The head is nearly entirely protected by hard bone; even the cheeks, which in the majority of fishes are covered with a naked or scaly skin, are in this genus cuirassed by the dilated infraorbital bones. There are no scales developed on any part of the body, but a series of hard and large scutes protects a greater or lesser portion of the sides. The first dorsal fin and the ventrals are transformed into pointed formidable spines, and joined to firm bony plates of the endoskeleton. With regard to the degree in which this armature is developed, not only do the species differ from each other, but almost every species shows an extraordinary amount of variation, so that some older naturalists have distinguished a multitude of species, whilst the majority of the present day are inclined to reduce their number considerably. About ten kinds may be taken to be specifically distinct.

So far as is known at present, all sticklebacks construct a nest for the reception of the spawn, which is jealously guarded by the male until the young are hatched, which event takes place in from ten to eighteen days after oviposition. He also protects them for the first few days of their existence, and provides them with food, until they gradually stray from their home. The construction of the nest varies in the different species.

Sticklebacks are short-lived animals; they are said to reach an age of only three or four years; yet their short life, at least that of the males, is full of excitement. During the first year of their existence, before the breeding-season begins, they live in small companies in still pools or gently flowing brooks. But with the return of the warmer season each male selects a territory, which he fiercely defends against all comers, especially against intruders of his own species and sex, and to which he invites all females, until the nest is filled with ova. At this period he also assumes a bridal dress, painted with blue and red tints. The eggs are of comparatively large size, one female depositing only from 50 to 100; but, as the females deposit their spawn in nests of different males, the number of ova contained in one nest does not exceed one hundred.

Of the species known not one has so wide a geographical range, and has so well been studied, as the common British Three-Spined Stickleback (*Gastrosteus aculeatus*). It is found everywhere in northern and central Europe, northern Asia, and North America. The development of its scutes and spines varies exceedingly, and specimens may be found without any lateral scutes and with short spines, others with only a few scutes and moderately sized spines, and again others which possess a complete row of scutes from the head to the caudal fin, and in which the fin-spines are twice as long and strong as in other varieties. On the whole, the smooth varieties are more numerous in southern than in northern localities. This species swarms in some years in prodigious num-



Gastrosteus aculeatus, var. *noveboracensis*, Three-Spined Stickleback.

bers; in Pennant's time amazing shoals appeared in the fens of Lincolnshire every seven or eight years. Their numbers may perhaps be conceived from the fact that a man employed in collecting them gained, for a considerable time, four shillings a day by selling them at the rate of a halfpenny a bushel. No instance of a similar increase of this fish has been observed in our time, and this possibly may be due to the diminished number of suitable breeding-places in consequence of the general introduction of artificial drainage. This species usually constructs its nest on the bottom, excavating a hollow in which a bed of grass, rootlets, or fibres is prepared; walls are then raised, and the whole is roofed over with the like material. The nest is an inch and more in diameter, with a small aperture for an entrance.

The Ten-Spined Stickleback (*Gastrosteus pungitius*) is so called from the number of spines usually composing its first dorsal fin, which, however, may be sometimes reduced to eight or nine or increased to eleven. It is smaller than the three-spined species, rarely exceeding 2 inches in length. Its geographical range nearly coincides with that of the other species, but it is more locally distributed, and its range in northern Asia is not known. With regard to its habits, it differs from the common species only in the selection of the site for its nest, which is generally placed among weeds above the bottom of the water. Breeding males are readily recognized at a distance by the intensely black colour of the lower parts of their body.

Both these species are for their size extremely voracious, causing no small amount of injury if allowed in breeding-ponds in which valuable fish are preserved. During the whole time they are not engaged in their breeding operations they are in pursuit of food. A small stickleback kept in an aquarium devoured, in five hours' time, seventy-four newly-hatched dace, which were about a quarter of an inch long. Two days after it swallowed sixty-two, and would probably have eaten as many every day, could they have been procured.

The Sea Stickleback (*Gastrosteus spinachia*) is a much larger and more slender species than those mentioned; it attains to a length of 7 inches, and is armed with fifteen short spines on the back. It is extremely common round the British coasts, but never congregates in large shoals. At suitable localities of the coast which are sheltered from the waves and overgrown with sea-weed, especially in rock-pools, one or two males establish themselves with their harems, and may be observed without difficulty, being quite as fearless as their freshwater cousins. Harbours and shallows covered with *Zostera* are likewise favourite haunts of this species, although the water may be brackish. The nest is always firmly attached to sea-weed, and sometimes suspended from an overhanging frond. This species inhabits only the northern coasts of Europe.

STIGMATIZATION, literally the infliction of *stigmata*, *i.e.*, marks tattooed or branded on the person, the term used with specific reference to the infliction of wounds like those of Christ.

An ancient and widespread method of showing tribal connexion, or relation to tribal deities, is by marks set upon the person; thus Herodotus, in describing a temple of Hercules in Egypt (ii. 113), says that it is not lawful to capture runaway slaves who take refuge therein if they receive certain marks on their bodies, devoting them to the deity. Some such idea is perhaps alluded to by Paul (Gal. vi. 17) in the words, "from henceforth let no man trouble me, for I bear branded on my body the stigmata of Jesus"; and some few authors have even understood the passage as referring to stigmatization in the modern sense (Molanus, *De Historia SS. Imaginum et Picturarum*, ed. Paquot, iii. 43, p. 365). Branding, as indicative of servi-

tude, is mentioned in many of the classics (Pliny, *H N*, xviii 3, Varro, *De Re Rustica*, i 18, Suetonius, *Caligula*, xxvii &c), and was forbidden by Constantine

In the period of persecution Christian martyrs were sometimes branded with the name of Christ on their foreheads (Pontius, "De Vit S Cypriani," *Biblioth Veterum Patrum*, iii p 472, § vii) This was sometimes self-inflicted as a disfigurement by nuns for their protection, as in the case of St Ebba, abbess of Coldingham (see Baronius, *Annales*, xv p 215, anno 870, also Tert, *De Vel Virg*) Some Christians likewise marked themselves on their hands or arms with the cross or the name of Christ (Procopius, *In Esaiam*, ed Curterius, p 496), and other voluntary mutilations for Christ's sake are mentioned (Matt xix 12, Fortunatus, *Life of St Rhadegund*, ed Migne, col 508, Palladius, *Lausiac History*, cxii, Jerome's *Letter to St Eustochium*, &c)

In the life of St Francis of Assisi we have the first example of the alleged miraculous infliction of stigmata (see vol ix p 692) While meditating on the sufferings of our Lord, in his cell on Mount Alverno, we are told by his biographers, Thomas of Celano and Bonaventura, that the Lord appeared to him as a seraph and produced upon his body the five wounds of Christ, of these we are told that the side wound bled occasionally, though Bonaventura calls it a scar, and the wounds in the feet had the appearance and colour of nails thrust through After his death St Clare endeavoured but in vain to extract one of these Pope Alexander IV and other witnesses declared that they had seen these marks both before and after his death (Raynaldus, ad annum 1255, p 27) The divinely-attested sanctity of their founder gave to the newly-established order of Franciscans a powerful impulse, so that they soon equalled and threatened to overshadow in influence the previously-founded order of St Dominic

The reputation of the latter order was, however, equally raised in the next century by the occurrence of the same wonder in the case of a sister of the third rule of St Dominic, Catherine Benincasa,—better known as St Catherine of Siena From her biographer's account we gather that she was subject to hystero-epileptic attacks, in one of which, when she was twenty-three years old, she received the first stigma (see vol v p 230) In spite of her great reputation, and the number of attesting witnesses, this occurrence was not universally believed in Pope Sixtus IV published a bull in 1475 ordering, on pain of anathema, the erasure of stigmata from pictures of St Catherine, and prohibiting all expressions of belief in the occurrence Pope Innocent VIII similarly legislated "ne de cætero S Catherina cum stigmatibus depingatur, neve de ejus stigmatibus fiat verbum, aut sermo, vel prædicatio ad tollendam omnem scandali occasionem" (see references in Raynaud, *De Stigmatisme*, cap xi, 1665) In the years which followed, cases of stigmatization occurred thick and fast,—now a Franciscan, now a Dominican, very rarely a religieuse of another order, showing the marks Altogether about ninety instances are on record, of which eighteen were males and seventy-two females Most of them occurred among residents in religious houses, and took place after the austerities of Lent, usually on Good Friday, when the mind was intently fixed on our Lord's Passion, and, from their occurrence being for the most part among members of the two orders to which St Francis and St Catherine belonged, the possibility of the reception of the marks was constantly before their eyes and thoughts The order of infliction in the majority of cases was that of the crucifixion, the first token being a bloody sweat, followed by the coronation with thorns, afterwards the hand and foot wounds appear, that of the side being the last The grade of the infliction varied in individual cases, and they may be grouped in the following series —

I As regards full stigmatization, with the visible production of the five wounds, and generally with the mark of the crown as well, the oldest case, after St Francis, is that of Ida of Louvain (1300), in whom the marks appeared as coloured circles, in Gertrude von Oosten of Delft (1344) they were coloured scars, and disappeared in answer to prayer as they also did on Dominica de Paradis, in Sister Pierona, a Franciscan, they were blackish grey They were true wounds in Margaret Ebnerin of Nuremberg (d. 1351), but they also disappeared in answer to her prayer (see her *Life*, Augsburg, 1717), as was the case with Brigitta, a Dominican tertiary (1390), and also with Lidwina An intermission is described in the marks on Johanna della Croce of Madrid (1524), in whom the wound in the side was large, and the others were rose coloured circular patches The marks appeared on each Friday and vanished on Sunday These emitted an odour of violets, but in Sister Apollonia of Volaterra they were fetid while she lived Angela della Pace (1634) was fully stigmatized at nine years of age, being even marked with the sponge and hyssop on the mouth, while Joanna de Jesu-Maria at Burgos (1613), a widow, who had entered the convent of Poor Clares, was marked in her sixtieth year To her in vision two crowns were offered,—one of flowers and one of thorns, she chose the latter and immediately was seized with such pain that her confessor heard her skull cracking This case was investigated by the officers of the Inquisition The stigmatization of Veronica Giuliani (1696) was also the subject of inquiry, and in this case the nun drew on a paper a representation of the images which she said were engraved on her heart On a post-mortem examination being made in 1727 by Prof Gentili and Dr Bordiga, the image of the cross, the scourge, &c, were said to have been impressed on the right side of the organ (*Vita della Veronica Giuliani*, by Salvatori, Rome, 1803) The case of Christina Stumbelen, a Dominican at Cologne, is noteworthy, as on her skull there was found a raised ridge or crown which was at first green, with red dots This relic is still preserved In Lucia di Narni (1546) the marks were variable, as they also were on Sister Maria di S Dominico On the body of St Margaret of Hungary the stigmata were found fresh and clear when her body was exhumed some time after her death for transportation to Presburg Other stigmatized persons were Elizabeth von Spalbeck, a Cistercian, Sister Coleta, a Poor Clare, Matilda von Stanz, Margaret Bruch of Endringen (1503), Maria Razzi of Chios (1582), Catharina Januensis, Elizabeth Reith of Allgau, Stieva zu Hamm in Westphalia, Sister Mary of the Incarnation at Pontoise, Archangela Tardera in Sicily (1608), Catharina Ricci in Florence (1590), and Joanna Maria della Croce, a Poor Clare at Roveredo (d 1673), upon whom the markings of the thorn crown and spear wound were especially deep

II In some cases, although the pains of stigmatization were felt, there were no marks apparent This occurred to Helen Brumsen (1285), Helena of Hungary (1270), Osanna of Mantua (1476), Columba Rocasani, Magdalena de Pazzis, Anna of Vargas, Hieronyma Carvaglio, Maria of Lisbon, a Dominican, Joanna di Vercelli, Stephania Soncinas, a Franciscan, Sister Christina, a Carthusian, and Joanna Rodriguez, a Poor Clare In the case of Ursula Aguir de Valenza, a tertiary of St Dominic (1608), and Catharine Cialina (d 1619) the pain was chiefly that of the crown of thorns, as it was also in Amelia Bicchieri of Vercelli, an Augustinian

III In a third series some of the marks were visible on the body, while others were absent or only subjectively indicated by severe pains The crown of thorns only was marked on the head of Vincentia Ferreria at Valencia (d 1515) and Philippa de Santo Tomaso of Montemor (1670), while according to Torellus the Augustinian Ritta von Cassla (d 1430) had a single thorn wound on the forehead The crown was marked on Catharina of Raconizio (b 1486), who also suffered a severe bloody sweat In the case of Stephano Quinzani, in Soncino (1457), there was a profuse bloody sweat and the wounds were intermitting, appearing on Friday and Saturday, vanishing on Sunday Blanche Gazman, daughter of Count Arias de Sagavedra (1564), was marked only on the right foot, as also was Catherine, a Cistercian nun The heart wound was visible in Christina Mirabilis (1232) Gabrielda de Piezolo (d 1473) died from the bleeding of such a wound, and similar wounds were described in Maria de Acosini in Toledo, Eustochia, a tertiary of St Francis, Clara de Bugny, a Dominican (1514), Cecilia Nobili, a Poor Clare of Nuceria (d 1655) In the last instance the heart wound was found after death—a three-cornered puncture A similar wound was seen in the heart of Martina de Arilla (d 1644) Maria Villana, a Poor Clare, daughter of the margrave of La Pella, was marked with the crown and the spear thrust, and after death the impresses of the spear, sponge, and reed were found on her heart (d 1670) The wound was usually on the left side, as in Sister Masrona of Grenoble, a tertiary of St Francis (1627), it was on the right in Margareta Columna, also a Clare In Maria de Sarmiento it was said to have been inflicted by a seraph in a vision

IV In a fourth set of cases the imprints were said to have been found on the heart, even though there was no surface marking Thus the Dominican Paula de St Thomas was said to have had the stigmata on her heart The heart of Claire of Montfaucon (1308) was said to have been as large as a child's head and impressed with the cross, the scourge, and the nails Similar appearances were found in Margaret of Citta di Capello and Johanna of Yepes (1591)

The instances of masculine stigmatization are few Benedict di Rhegio, a Capuchin at Bologna, had the marks of the crown (1602), Carolus Sazia, an ignorant lay brother, had the wound in his side Dodo, a Præmonstratensian lay brother, was fully stigmatized, as also was Philip de Aqueria The marks after death were found on the heart of Angelos del Pas, a minorite of Perpignan, as also on Matheo Carery in Mantua, Melchior of Arazel in Valentia, Cherubin de Aviliana (an Augustinian), and Agolini of Milan Walter of Strasburg, a preaching friar (1264), had the heart-pain but no mark, and the same was the case with a Franciscan, Robert de Malatestis (1430), and James Stephanus On Nicholas of Ravenna the wounds were seen after death, while John Gray, a Scotsman, a Franciscan martyr, had one wound on his foot

Within the last hundred years several cases have occurred Anna Katharina Emmerich, a peasant girl born at Munster in 1774, afterwards an Augustinian nun at Agnetenberg, was even more famous for her visions and revelations than for the stigmata Biographies, with records of her visions, have been published by Brentano at Munich in 1852 and the Abbé Cazalès at Paris (1870) Colombe Schanolt of Bamberg (1787) was fully stigmatized, as also was Rose Serra, a Capuchin of Ozieri in Sardinia (1801), and Madeleine Lorger (1806) Two well-known cases occurred in Tyrol,—one "L'Ecstatica" Maria von Moil of Caldaro, a girl of noble family, stigmatized in 1839, the other "L'Addolorata" Maria Dominica Lazzari, a miller's daughter at Capriana, stigmatized in 1835 (see Boré, *Les Stigmatisees du Tyrol*, Paris, 1846) A case of the second class is that of Elizabeth Eppinger of Niederbrunn in Bavaria (1814), reported on by Kuhn An interesting example of stigmatic trance also occurred in the case of a Protestant young woman in Saxony in 1820, who appeared as if dead on Good Friday and Saturday and revived on Easter Sunday

The last case recorded is that of Louise Lateau, a peasant girl at Bois de Haine, Hainault, upon whom the stigmata appeared April 24, 1868 This case was investigated by Professor Lefebvre of Louvain, who for fifteen years was physician to two lunatic asylums In her there was a periodic bleeding of the stigmata every Friday, and a frequent recurrence of the hystero-cataleptic condition Her biography has been written by Lefebvre and published at Louvain (1870)

On surveying these ninety cases, we may discount a certain number, including all those of the second class, as examples of subjective sensations suggested by the contemplation of the pains of crucifixion A second set, of which the famous case of Jetzer (Wirz, *Helvetische Kirchengeschichte*, 1810, iii p 389) is a type, must be also set aside as obvious and intentional frauds produced on victims by designing persons. A third series, and how large a group we have not sufficient evidence to decide, we must regard as due to the irresponsible self-infliction of injuries by persons in the hystero epileptic condition, those perverted states of nervous action which Charcot has done so much to elucidate To any experienced in this form of disease, many of the phenomena described in the records of these examples are easily recognizable as characteristic of the hystero-epileptic state

There are, however, some instances not easily explained, where the self-infliction hypothesis is not quite satisfactory. Parallel cases of physical effects due to mental suggestion are well authenticated Beaunis vouches for rubefaction and vesication as produced by suggestion in the hypnotic state, and Bourru and Burot describe a case, still under observation, of bloody sweat, and red letters marked on the arm by simple tracing with the finger See *Congrès Scientifique de Grenoble*, *Progrés Medicale*, 29 Aug 1885, and Berjon's *La Grande Hystérie chez l'Homme*, Paris, 1886 We know so little of the trophic action of the higher nerve centres that we cannot say how far tissue nutrition can be controlled in spots That the nerve centres have a direct influence on local nutrition is in some cases capable of experimental demonstration, and, in another sphere, the many authenticated instances of connexion between maternal impression and congenital deformity seem to indicate that this trophic influence has wider limits and a more specific capacity of localization than at first sight seems possible There is no known pathological condition in which blood transudation can take place through an unbroken skin

STILICHO, FLAVIUS, Roman general and statesman, was of Vandal origin, and was born about 359 A D At an early age he entered the imperial army, where his father before him had served under Valens, and he speedily attained high promotion He had already become magister equitum when in 384 he was sent by Theodosius as his ambassador to Persia, his mission was very successful, and soon after his return he was made comes domesticus and commander-in-chief, receiving also in marriage Serena, the emperor's niece and adoptive daughter Theodosius, when dying, made Stilicho and Serena the guardians of Honorius and his other children. Honorius, in 398, was married to Stilicho's daughter Maria, and in 408 to her sister Thermantia It was by Stilicho that Alaric in 396 was compelled to quit the Peloponnesus (see ALARIC), and that in 398 the revolt of the Mauretanian prince Gildo was repressed Stilicho again encountered Alaric at Pollentia in 402, and at Verona in 403, compelling his retreat into Illyria, and was rewarded with a triumph on his return to Rome In 405 he almost annihilated the army of Radagaisus, the leader of the Ostrogoths, at Fiesole The arrangements into which he subsequently entered with Alaric (see ALARIC) were made use of by his enemies to alienate the emperor from him, and when at last revolt was the only course that might possibly have saved him his continued loyalty proved fatal Abandoned by his troops he fled to Ravenna, and, having been induced by false promises to quit the church in which he had taken sanctuary, he was beheaded on August 23, 408 Stilicho is the hero of much of the poetry of CLAUDIAN (*q v*)

STILL, JOHN (*c* 1543–1607), bishop of Bath and Wells, and now best known as the probable author ("Mr S, Master of Arts") of *Gammer Gurton's Needle*, the earliest comedy but one in the English language (see DRAMA, vol vii. p 428), was a native of Grantham, Lincolnshire, and

was born about 1543 He became a student of Christ's College, Cambridge, where he duly graduated and took orders He was appointed in 1570 Lady Margaret's professor of divinity in his university, subsequently held livings in Suffolk and Yorkshire, and was master successively of St John's College (1574) and of Trinity College (1577) Still was raised to the bishopric of Bath and Wells in 1592, and, after enjoying considerable fame as a preacher and disputant, he died on February 26, 1607, leaving a large fortune from lead mines discovered in the Mendip Hills

STILLING, HEINRICH See JUNG

STILLINGFLEET, EDWARD (1635–1699), a conspicuous figure in the church of the Restoration, was descended from the Stillingfleets of Stillingfleet, in the neighbourhood of York, and was born at Cranbourne in Dorset on the 17th April 1635 There and at Ringwood he received his preliminary education, and at the age of thirteen was entered at St John's College, Cambridge, as Isaac Barrow five years before and at the same age had been entered at Peterhouse He took his bachelor's degree in 1652, and in the following year was elected to a fellowship After residing as tutor first in the family of Sir Roger Burgoin in Warwickshire and then with the Hon Francis Pierrepont in Nottingham, he was in 1657 presented by the former to the living of Sutton in Bedfordshire Here he brought to completion and published (1659) his *Irenicum*, in which he sought to give expression to the prevailing weariness of faction and to find some ecclesiastical compromise in which all could conscientiously unite Schemes of comprehension were then the most familiar topics of conversation There seemed every probability that a moderate Episcopacy might attract all parties, and it was to be expected that a learned and able scholar fresh from the atmosphere of Cambridge Platonism should desire to help present entanglements towards a liberal solution Much may still be learned from his cogent and earnest exposition of the great principle that it is unwarrantable for the church to make other conditions of her communion than our Saviour did of discipleship In 1662 he reprinted the *Irenicum* with an appendix, in which he sought to prove that "the church is a distinct society from the state, and has divers rights and privileges of its own, resulting from its constitution as a Christian society, and that these rights of the church cannot be alienated to the state after their being united in a Christian country" In the same year the country gave its answer to his and all similar proposals in the Act of Uniformity, which, by requiring that all clergymen should be episcopally ordained and should use the revised liturgy, lost to the church of England such men as Richard Baxter, John Howe, and Philip Henry Stillingfleet's actions were as liberal as his opinions He sheltered in his rectory at Sutton one ejected minister and took for another a large house to be used as a school But, as time wore on, his liberalism degenerated and gave occasion to Howe's remark that the rector of Sutton was a very different person from the dean of St Paul's But, though in 1680 he published his *Unreasonableness of Separation*, his willingness to serve on the ecclesiastical commission of 1689, and the interpretation he then proposed of the damnatory clauses of the Athanasian creed, are proof that to the end he leaned towards toleration Another work which Stillingfleet published in 1662 won for him the confidence and admiration of his church This was his *Origines Sacræ, or a Rational Account of the Christian Faith as to the Truth and Divine Authority of the Scriptures and the Matters therein contained* Rendered obsolete though it be by the general advance of the discussion, this apologetic made a deep impression at the time, and rapid preferment followed its publication Henchman, bishop of London, employed him to write a vindication of Laud's answer to Fisher the Jesuit In 1665 the earl of Southampton presented him to St Andrew's, Holborn, two years later he became prebendary of St Paul's, in 1668 chaplain to Charles II, in 1670 canon residentiary and in 1677 dean of St Paul's Finally, but under different auspices, he was consecrated bishop of Worcester 13th October 1689 During these years he was ceaselessly engaged in controversy with Nonconformists, Romanists, Deists, and Socinians His unrivalled and various learning, his dialectical expertness, and his massive judgment rendered him a formidable antagonist, but the respect entertained for him by his opponents was chiefly aroused by his recognized love of truth and superiority to personal considerations He had the courage, along with the saintly and noble-minded Ken and the other six bishops, to incur the anger of James II by resisting his proposed Declaration of Indulgence (1688) Strangely enough, he crossed swords both with Dryden and Locke,—with Dryden in connexion with the papers favourable to the authority of the Church of Rome which were found in the strong box of Charles II and were supposed to have been written by him, and with Locke because the theologian considered that the philosopher's definition of substance was prejudicial to the doctrine of the Trinity In most of his writings there is a small residuum of permanent value The range of his learning is most clearly seen in his *Bishops' Right to Vote in Parliament in Cases Capital* His *Origines Britannicæ, or Antiquities of the British Church* (1685), is a surprising mixture of critical and uncritical research, and his *Discourse concerning the True Reason of the Sufferings of Christ* (1669), written in answer to Crellius, contains a most forcible statement of the doctrine of Christ's substitution So handsome in person as to have earned the sobriquet of "the beauty of holiness," Stillingfleet was twice married,—first to Andrea, daughter of William Dobbyns of Wormington, by whom he had two daughters, who died in infancy, and one son, afterwards to Elizabeth, daughter of Sir Nicholas Pedley, by whom he had seven children He died in his house at Westminster, 28th March 1699, and was buried in his own cathedral, where a handsome monument briefly records his virtues His library was bought by Marsh, archbishop of Armagh, to form the foundation of a public library in Dublin

A collected edition of his works, with life prefixed, was published in London (1710), and a most useful edition of *The Doctrines and Practices of the Church of Rome Truly Represented* was published in 1845 by Dr Cunningham

STILLWATER, a city of the United States, at the head of Washington county, Minnesota, on the west bank of the St Croix river, 18 miles north-east of St Paul It is a great centre of the lumber trade, contains a State prison, a high school, and a public library, and increased its population from 4124 to 9055 between 1870 and 1880

STILT, or LONG-LEGGED PLOVER, a bird so called for reasons obvious to any one who has seen it, since, though no bigger than a Snipe, the length of its legs (their bare part measuring 8 inches), in proportion to the size of its body, exceeds that of any other bird's The first name (a translation of the French *Échasse*, given in 1760 by Brisson) seems to have been bestowed by Rennie only in 1831, but, recommended by its definiteness and brevity, it has wholly supplanted the second and older one The bird is the *Charadrius himantopus*[1] of Linnæus, the *Himantopus*

[1] The possible confusion by Pliny's transcribers of this word with *Hæmatopus* has been already mentioned (OYSTERCATCHER, vol xviii p 111, note 2) *Himantopus*, with its equivalent *Loripes*, "by an awkward metaphor," as remarked by Gilbert White, "implies that the legs are as slender and pliant as if cut out of a thong of leather"

candidus or *melanopterus* of modern writers, and belongs to the group *Limicolæ*, having been usually placed in the Family *Scolopacidæ*, though it might be quite as reasonably referred to the *Charadriidæ*, and, with its allies to be immediately mentioned, would seem to be not very distant from *Hæmatopus*, notwithstanding the wonderful development of its legs and the slenderness of its bill.

The very peculiar form of the Stilt naturally gave Buffon occasion (*Hist. Nat. Oiseaux*, viii. pp. 114–116) to lament the shortcomings of Nature in producing an animal with such "enormous defects,"—its long legs in particular, he supposed, scarcely allowing it to reach the ground with its bill. But he failed to notice the flexibility of its proportionately long neck, and admitted that he was ill-informed as to its habits. No doubt, if he had enjoyed even so slight an opportunity as occurred to a chance observer (*Ibis*, 1859, p. 397), he would have allowed that its structure and ways were in complete conformity, for the bird obtains its food by wading in shallow water and seizing the insects that fly over or float upon its surface or the small crustaceans that swim beneath, for which purpose its slender extremities are, as might be expected, admirably adapted. Widely spread over Asia, North Africa, and Southern Europe, the Stilt has many times visited Britain—though always as a straggler, for it is not known to breed to the northward of the Danube valley,—and its occurrence in Scotland (near Dumfries) was noticed by Sibbald so long ago as 1684. It chiefly resorts to pools or lakes with a margin of mud, on which it constructs a slight nest, banked round or just raised above the level so as to keep its eggs dry (*Ibis*, 1859, p. 360); but sometimes they are laid in a tuft of grass. They are four in number, and, except in size, closely resemble those of the OYSTERCATCHER (vol. xviii. p. 111). The bird has the head, neck, and lower parts white, the back and wings glossy black, the irides red, and the bare part of the legs pink. In America the genus has two representatives, one[1] (fig. 1) closely resembling that just described, but rather smaller and with a black crown and nape.

FIG. 1.—Black-Necked American Stilt. (After Gosse.)

This is *H. nigricollis* or *mexicanus*, and occurs from New England to the middle of South America, beyond which it is replaced by *H. brasiliensis*, which has the crown white. The Stilt inhabiting India is now recognized to be *H. candidus*, but Australia possesses a distinct species, *H. novæ-hollandiæ*, which also occurs in New Zealand, though that country has in addition a species peculiar to it, *H. novæ-zelandiæ*, differing from all the rest by assuming in the breeding-season an altogether black plumage. Australia, however, presents another form, which is the type of the genus *Cladorhynchus*, and differs from *Himantopus* both in its style of plumage (the male having a broad bay pectoral belt), in its shorter tarsi, and in having the toes (though, as in the Stilt's feet, three in number on each foot) webbed.

Allied in many ways to the Stilts, but differing in many undeniably generic characters, are the birds known as Avosets,[2] forming the genus *Recurvirostra* of Linnæus. Their bill, which is perhaps the most slender to be seen in the whole Class, curves upward towards the end, and has given the oldest known species two names which it formerly bore in England,—"Cobbler's-awl," from its likeness to the tool so called, and "Scooper," because it resembled the scoop with which mariners threw water on their sails. The legs, though long, are not extraordinarily so, and the feet, which are webbed, bear a small hind toe.

This species (fig. 2), the *R. avocetta* of ornithology, was of old time plentiful in England, though doubtless always restricted to certain

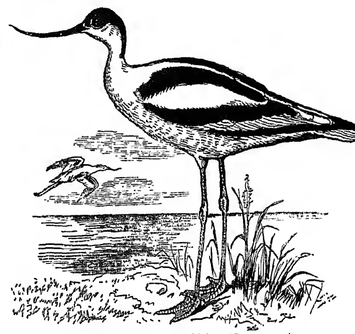

FIG. 2.—Avoset. (After Naumann.)

localities. Charleton in 1668 says that when a boy he had shot not a few on the Severn, and Plot mentions it so as to lead one to suppose that in his time (1686) it bred in Staffordshire, while Willughby (1676) knew of it as being in winter on the eastern coast, and Pennant in 1769 found it in great numbers opposite to Fossdyke Wash in Lincolnshire, and described the birds as hovering over the sportsman's head like Lapwings. In this district they were called "Yelpers" from their cry;[3] but whether that name was elsewhere applied is uncertain. At the end of the last century they frequented Romney Marsh in Kent, and in the first quarter of the present century they bred in various suitable spots in Suffolk and Norfolk,—the last place known to have been inhabited by them being Salthouse, where the people made puddings of their eggs, while the birds were killed for the sake of their feathers, which were used in making artificial flies for fishing. The extirpation of this settlement took place between 1822 and 1825 (*cf.* Stevenson, *Birds of Norfolk*, ii. pp. 240, 241).[4] The Avoset's mode of nesting is much like that of the Stilt, and the eggs are hardly to be distinguished from those of the latter but by their larger size, the bird being about as big as a LAPWING (vol. xiv. p. 308), white, with the exception of its crown, the back of the neck, the inner scapulars, some of the wing-coverts and the primaries, which are black, while the legs are of a fine light blue. It seems to get its food by working its bill from side to side in shallow pools, and catching the small crustaceans or larvæ of insects that may be swimming therein, but not, as has been stated, by sweeping the surface of the mud or sand—a process that would speedily destroy the delicate bill by friction. Two species of Avoset, *R. americana* and *R. andina*, are found in the New World; the former, which ranges so far to the northward as the Saskatchewan, is distinguished by its light cinnamon-coloured head, neck, and breast, and the latter, confined so far as known to the mountain lakes of Chili, has no white in the upper parts except the head and neck. Australia produces a fourth species, *R. novæ-hollandiæ* or *rubricollis*, with a chestnut head and neck; but the European *R. avocetta* extends over nearly the whole of middle and southern Asia as well as Africa.

A recent proposal (*Ibis*, 1886, pp. 224–239) to unite the Avosets and Stilts in a single genus seems to have little to recommend it but its novelty, and will hardly meet with acceptance by systematists. (A. N.)

[1] This species was made known to Ray by Sloane, who met with it in Jamaica, where in his day it was called "Longlegs."

[2] This word is from the Bolognese *Avosetta*, which is considered to be derived from the Latin *avis*—the termination expressing a diminutive of a graceful or delicate kind, as *donnetta* from *donna* (Prof. Salvadori *in epist.*).

[3] *Cf.* "Yarwhelp" (GODWIT, vol. x. p. 720) and "Yaup" or "Whaup" (CURLEW, vol. vi. p. 711). "Barker" and "Clinker" seem to have been names used in Norfolk.

[4] The same kind of lamentable destruction has of late been carried on in Holland and Denmark, to the extirpation probably of the species in each country.

STIRLING, a midland county of Scotland, is bounded N by Perthshire, N E by Clackmannan and the Firth of Forth, S E by Linlithgowshire, S by Lanarkshire and a detached portion of Dumbartonshire, and S W and W by Dumbartonshire In the north-east there are two isolated portions,—one forming the parish of Alva, bounded partly by Clackmannan and partly by Perthshire, and the other forming part of the parish of Logie and bounded by Perthshire The outlines of the main portion are extremely irregular, the boundary on the north following for the most part the windings of the Forth, while on the west it passes through the middle of Loch Lomond, and on the south coincides to a considerable extent with various streams The extreme length of the county from north-west to south-east is about 45 miles, and the greatest breadth from north to south about 18 miles The land area is 286,338 acres, and the total area 298,579 acres, or about 466 square miles Apart from the district round Loch Lomond, the principal charm of the scenery of Stirlingshire is in the views of the valley of the Forth with the winding river, and for background the distant peaks of the Grampians, or the nearer ranges of the Ochils, which encroach on the north-eastern corner and detached sections of the county The valley of the Forth runs along nearly the whole of the northern border, widening towards the east The centre of the county from north-east to south-west is occupied by the broad irregular ranges of the Lennox Hills, which are known under four different names, according to the parishes in which they are principally situated,—the Gargunnock Hills (attaining a height of 1591 feet), the Fintry Hills (1676), the Kilsyth Hills (1393), and the Campsie Fells (1894) Nearly the whole of the county to the north-east of Loch Lomond is occupied by a spur of the Grampians, reaching in Ben Lomond a height of 3192 feet Besides Loch Lomond, situated partly in Dumbartonshire, and Loch Katrine, which bounds the county at its north-western corner, the principal lakes are Loch Arklet to the south of Loch Katrine, Loch Coulter, in the south of St Ninians parish, Loch Elling in Falkirk parish, and Black Loch partly in Lanarkshire The river Forth, from its junction with the Kelty near Gartmore, forms the northern boundary of the county, except where it bounds on the north the part of Kippen parish which is in Perthshire and separates a portion of Lecropt parish from that of St Ninians and a portion of Logie from that of St Ninians and Stirling It receives from the north the Teith, which touches the county at Lecropt parish, and the Allan, which separates the parishes of Lecropt and Logie, and from the south the Boquhan burn, the Touch burn, and the Bannock burn The Carron water flows eastwards from the Fintry Hills to the Firth of Forth at Grangemouth On the south there are a number of streams which form at various places the boundary of the county,—the Endrick water flowing westwards from the Fintry Hills to Loch Lomond, the Kelvin from near Kilsyth flowing south-westwards to the Clyde, and the Avon from Lanarkshire flowing north-eastwards to the Firth of Forth The Forth and Clyde Canal crosses the south-eastern corner of the county from Castlecary to Grangemouth

The whole of the district to the north of Loch Lomond is occupied by the crystalline schists of the Highlands, which, by the existence of a great fault, are connected on the east with the Old Red Sandstone, which occupies the broad valley between the base of the Highland hills and the chain of the Ochils These latter heights, portions of which are included in detached areas of the county, consist of volcanic rocks associated with the Old Red Sandstone (see vol x p 343) The Lennox Hills in the centre of the county are formed by volcanic rocks of Carboniferous age resting on strata of red and white sandstone (see vol x p 346) The lower grounds are deeply buried under glacial drifts, and conspicuously marked by broad terraces that represent former sea-margins On one of these, at a height of 50 feet above the present sea-level, lies the Carse of Falkirk Another stands at an elevation of about 100 feet There are saline mineral springs at Bridge of Allan

The coalfield runs obliquely along the south-east of the county, the principal seams being in Denny, Kilsyth, Larbert, Falkirk, and Slamannan parishes Ironstone, fireclay, and oil-shale are also found Limestone is extensively wrought in the Campsie district, and there are a number of sandstone quarries in various parts of the county The total output of coal in 1884 was 1,182,891 tons, of ironstone 75,351 tons, of fireclay 15,872, and of oil-shale 4535

Agriculture —According to the landowners return of 1872–73 the land was held by 4257 proprietors, possessing 284,751 acres, at an annual valuation of £521,407, an average value all over of £1, 16s 3¾d Of the proprietors 3409 possessed less than one acre The following possessed over 5000 acres each —Duke of Montrose, 68,878, William Forbes, 13,041, Rear-admiral Sir William Edmonstone, 9778, Hon Mrs Margaret Lennox, 7606, Alex Graham Speirs, 7172, W C G Bontine, 6931, Lieutenant Col John Murray, 6813, Sir Alex C R Gibson-Maitland, 6023, Henry Fletcher Campbell, 5679, and James Johnstone, 5340 The two arable soils of Stirlingshire are distinguished locally as carse and dryfield, the remainder of the county being occupied by mountain pasture land, moor, and moss The Carse of Stirling extends along the banks of the Forth from Buchlyvie to the eastern extremity of the county,— a length of about 28 miles, with a breadth varying from 1 to 4 miles, the total area being about 30,000 acres The carse soil consists of the finest clays, without stones, but interspersed with strata of marine shells It has been partly reclaimed from superincumbent peat moss, of which there are still considerable areas adjoining it It requires a great deal of labour, but, by means of draining subsoil ploughing, and the use of lime, has been rendered one of the most fertile soils in Scotland, being specially well adapted for wheat and beans The dryfield occupies the slopes of the hills above the carse and the valleys in the interior of the county, which constitute the more fertile portions, the crops for which it is best suited being potatoes and turnips A great part of the dryfield has been reclaimed from moor within the present century The Lennox Hills, occupying about a fourth of the total area of the county, form one of the most valuable tracts of pasture land in Scotland The following table gives a classification of the holdings in 1875 and 1885 —

	50 acres and under		50 to 100 acres		100 to 300 acres		300 to 500 acres		500 to 1000 ac		Above 1000 ac		Total	
	No	Acres	No	Acres	No	Acres	No	Acres	No	Ac	No	Ac	No	Acres
1875	789	13 130	382	28,493	329	52,080	29	10,411	7	4299	1	1418	1537	109,831
1885	725	12,550	363	27,876	370	59,418	28	10,325	5	3489	1	1418	1492	115,076

According to the agricultural returns for 1886, out of a total of 295,285 acres 115,477, or nearly 39 per cent, were arable land, the area under corn crops amounting to 29,306 acres, under green crops to 8752, rotation grasses 30,664, permanent pasture 45,232, flax 15 and fallow 1508 Oats, the principal corn crop, occupied 19,662 acres, wheat 2065 acres (a decrease of about one half within twenty years), barley 4297 acres, rye 30, beans 3221, and pease 31 Of green crops the principal are potatoes (3500 acres) and turnips (4623 acres) Considerably more than half of the arable area is occupied by rotation grasses and permanent pasture, and their acreage is constantly increasing, which is sufficiently accounted for by the steady increase in the numbers of sheep and cattle The number of horses in 1886 was 4616, of which 3176 were used solely for purposes of agriculture, and 1440 were unbroken horses and mares kept solely for purposes of breeding The Clydesdale breed are in general use on the larger farms Cattle in 1886 numbered 29,422, of which 10,745 were cows and heifers in milk or in calf, and 8634 were other cattle two years old and above Butter-making is largely practised on the dryfield farms, the Ayrshire being the principal breed of cows, but cattle feeding is also an important industry, for which Irish cattle and cross breeds are frequently bought, a considerable number of shorthorns being also reared Sheep, chiefly blackfaced, for which there is extensive pasturage on the Lennox Hills and the slopes of the Grampians, numbered 109,897 in 1886, and pigs 1775

Though, as is evident from the remains of trees in the mosses, an extensive district of the county was at one time occupied by forest, it is now comparatively devoid of timber, the area under woods in 1881 being only 12,483 acres There is a natural tendency to the growth of birch on the lower slopes of the mountains in the parishes

of Buchanan and Drymen, and oaks grow extensively on the borders of Loch Lomond. Larch and Scotch firs principally occupy the modern plantations in the other parts of the county. In 1886 there were only 31 acres under orchards, 27 under market gardens, and 53 under nursery grounds.

Manufactures.—The Carron ironworks, founded in 1760, for a long time led the van in British iron manufacture, and are still among the most extensive in the kingdom. The Falkirk ironworks, founded in 1819, are the next to them in importance in the county, but there are many others in the same district. The woollen manufacture is next to iron in importance. It includes carpets, tartans, shawls, and tweeds, the principal seats of the industry being Alva, Bannockburn, Cambusbarron, and Stirling. Calico printing is carried on in the western part of the county, especially at Campsie and Milngavie. There are chemical works at Stirling, Falkirk, Denny, and Campsie. Throughout the county there are a considerable number of breweries and distilleries. At Grangemouth, the principal port in the county, shipbuilding is carried on.

Administration and Population.—Stirling is included with Dumbarton and Clackmannan in the same sheriffdom, but has two sheriff-substitutes, who sit at Stirling and Falkirk respectively, and there are prisons in both towns. The high court of justiciary holds circuit courts at Stirling. There are 21 entire civil parishes within the county and parts of 5 others. Stirling (population 12,194) is a royal and police burgh, Falkirk (13,170) a police burgh and burgh of regality, Kilsyth (5405) a police burgh and burgh of barony, and Alva (4961), Bridge of Allan (3005), Denny and Dunipace (4080), Grangemouth (4424), and Milngavie (2636) police burghs. In addition to these the following places had each upwards of 2000 inhabitants: Bannockburn (2549), Lennoxtown (3249), and Stenhousemuir (2617). From 39,761 in 1765 the population of the county had by 1801 increased to 50,825, by 1831 to 72,621, by 1861 to 91,926, by 1871 to 98,176, and by 1881 to 112,443, of whom 56,147 were males and 56,296 were females. The number of persons to the square mile is 251, and in point of density Stirling ranks ninth among the counties of Scotland. One member is returned to parliament by the county, and Stirling and Falkirk are members of separate districts of burghs, which are respectively named from them, each returning one member.

History.—In 81 A.D. the Romans under Agricola penetrated as far north as the firths of Clyde (Clota) and Forth (Bodotria). To secure their conquests they erected between these a line of forts or *præsidia*, generally two miles apart. In 139 Lollius Urbicus erected along the line of the forts the rampart of Antoninus's wall, afterwards known as Graham's dyke. The wall, after crossing the parish of East Kilpatrick, passed outside the present county of Stirling, till it reached Castlecary, whence it passed by Camelon and Falkirk to Carriden in Linlithgowshire. Castlecary, where many Roman remains have been found, was perhaps the principal Roman station on the line of the wall, and there was another important one at Camelon. A Roman road, the Camelon causeway, passed eastwards from Castlecary to the south of the rampart, and after two miles crossed it and held on to Camelon, whence it went northward by Bannockburn, St Ninians, and Stirling to the Forth, where there was an important station near the present bridge of Drip. Thence it passed north by Keir to Dunblane. To the north-east of the Carron ironworks there was at one time a finely preserved circular Roman building, called Arthur's Oon (oven) or Julius's Hof, which was demolished in 1743, but of which a drawing is preserved in Camden's *Britannia*. In the parish of Dunipace are two beautiful mounds called "the Hills of Dunipace," which some have supposed to have been erected as monuments of peace between the Romans and Caledonians, but which are more probably of natural origin. The remains of what was supposed to have been an early British stronghold were discovered at Torwood in 1864. A group of cairns at Craigmaddie, near Milngavie, is supposed to mark the scene of a battle between the Picts and Danes. Among the remains of old feudal castles may be mentioned Graham's castle, among the Fintry Hills, which belonged to Sir John de Graham, who was killed in the battle of Falkirk in 1298; Herbertshire, on the north bank of the Carron near Denny, originally a royal hunting seat, and still one of the finest embattled residences in the county (now a boarding school); the ancient keep of Castlecary, partly destroyed by the Highlanders in 1715; Torwood, surrounded by the remains of the Caledonian forest, in one of the oaks of which Wallace took refuge; and the round tower of Carnock, called Bruce's castle, of unknown history. Sir William Wallace lived occasionally with his uncle, the parson of Dunipace, and the county is specially associated with his exploits and those of Robert Bruce, being the scene of some of the principal battles in the struggle for Scottish independence (Stirling bridge, September 10, 1297; Falkirk, July 22, 1298; Bannockburn, June 24, 1314). At Sauchieburn, 11th June 1488, James III. was defeated by his insurgent nobles, and during his flight, having stopped at a cottage in the village of Milton, was there stabbed to death. Kilsyth saw the defeat of the Covenanters by Montrose, 15th August 1645, a result which for a time laid Scotland at Montrose's feet; and a hundred years afterwards—17th January 1746—the Highlanders under Prince Charles Edward routed the Hanoverians at Falkirk.

See Sir Robert Sibbald's *Description of Stirlingshire*, 1710, and Nimmo's *History of Stirlingshire*, 1777 (MacGregor Stirling's edition is the best). (T. F. H.)

Plan of Stirling

STIRLING, a royal and parliamentary burgh and the county town of Stirlingshire, is finely situated on the slopes of an isolated eminence overlooking the valley of the Forth and abruptly precipitous towards the north-west, at the junction of several railway lines, 36 miles west-north-west of Edinburgh and 30 north-north-east of Glasgow. Originally the town was protected on all the accessible sides of the rock by a wall, of which there are still some remains at the southern end of the Back Walk. There were two principal entries to the town,—the South Port, originally 100 yards more to the west of the present line of Port Street, and the bridge over the Forth to the north. The earliest bridge was at Kildean, a mile to the west; the existing old bridge, now disused, probably dates from about the end of the 13th century; the new bridge was erected in 1829, from the designs of Stevenson, at a cost of £17,000. The streets of the old town are for the most part steep, narrow, and irregular, and contain a large number of quaint and antique dwellings. The town has now much outgrown its ancient limits, and the surrounding suburbs on the low grounds contain numerous villas. The castle crowning the eminence, and commanding a splendid panoramic view of the wide valley between the Lennox Hills and the Highland mountains and Ochils, with the links of the Forth and the widening estuary to the east, is of unknown antiquity, but from the time that Alexander I. died within its walls in 1124 till James VI. ascended the throne of England it was intimately associated with the fortunes of the Scottish monarchs, and after the accession of the Stuarts it became a favourite royal residence. The building was extended by James III., who erected the parliament hall, now used as a barrack-room. The palace, begun by James V. and finished in the reign of Mary, is

at the south-west of the fortress, and forms a quadrangle, the front and pillars of which are adorned by quaintly sculptured figures. The royal chapel founded by Alexander I, rebuilt in the 15th century, and again by James VI, was subsequently converted into an armoury and is now used as a store. To the west of it is the Douglas room, the scene of the treacherous murder of William, eighth earl of Douglas, by James II in 1452. Below the castle on the north-east is the road of Ballangeich, which supplied a fictitious title to James V when wandering in disguise. Beyond it is the Gowan or Gowlan Hill, at the west corner of which is Mote Hill or Heading Hill, where Murdoch, duke of Albany, and several of his relatives were beheaded in 1425. On the north-east side of the esplanade a statue of King Robert Bruce was erected in 1877. Below the castle rock to the south-west were the king's gardens, now laid out in grass, with an octagonal mound, called the King's Knot, in the centre. Farther south is the King's Park, now used for recreation, and as a drill ground. In the cemetery to the south of the castle esplanade there are a number of interesting monuments. Near the main entrance to the esplanade is the building called Argyll's Lodging, erected by the poet, Sir William Alexander, who was created earl of Stirling by Charles I. It passed into the possession of the Argylls in 1640, and was the headquarters of John, duke of Argyll, during the rebellion of 1715. South-west of it is Mar's Work, the ruins of the palace built as a residence by the earl of Mar about 1570, from the ruins of Cambuskenneth Abbey. Next to the castle the most interesting public building is the Greyfriars church, some portions of which date from the 13th century, although the monastery with which it was connected was not founded till 1494. The greater part of it is in the Later Pointed style. The church was the scene of the coronation of James VI, 29th July 1567, when John Knox preached the coronation sermon. The site of the Dominican monastery founded by Alexander II in 1223 is now occupied by the National Bank. In the immediate neighbourhood of Stirling, on the other side of the Forth, in Clackmannan county, is the beautiful ruin of Cambuskenneth Abbey, chiefly Early English or First Pointed, founded by David I in 1147 for canons regular, associated with the meeting of parliaments and other interesting events in Scottish history, and the burial place of James III and his queen, Margaret of Denmark.

The principal secular buildings are the old town-house, erected in 1701, the new town buildings, the jail, erected in 1848 at a cost of £12,000, the county buildings (1875, £15,000), the Smith institute, founded by the bequest of £22,000 and a valuable collection of paintings by Thomas Stewart Smith, and embracing a picture gallery, a museum, and a reading room, the public halls (1883, £12,000), and the high school (1855, £5000, now being extended at a cost of £8000). Among the benefactions are Cowane's hospital, founded by the bequest of John Cowane, dean of guild in 1633, for twelve decayed members of the guildry, but the distribution of the charity has since been altered, and the building erected in 1639 now forms the guild hall, Spittal's hospital, founded by Robert Spittal, tailor to James IV, about 1530 for decayed tradesmen, Allan's hospital, founded in 1725 for the maintenance of children of poor townsmen, and Cunningham's mortification, founded in 1808 with an endowment of £4000 for the clothing and schooling of sons of mechanics. By the operation of the Endowed Schools and Hospitals Act the charities are now largely devoted to education.

As early as the 15th century Stirling had a trade with the Netherlands in worsted cloth, shalloons, stockings, and thread, but the manufactures afterwards declined. The cotton manufacture carried on in the beginning of the present century has now entirely ceased. During the last century the manufacture of tartans and carpets was carried on, but this also languished about the end of the century, and was not revived till about 1820. The woollen manufacture is now the staple industry, the principal goods being carpets, tartans, tweeds, and shawls. There are also breweries, coachbuilding works, and agricultural implement works. The population of the royal burgh in 1871 was 10,873, and in 1881 12,194. The population of the parliamentary burgh, which includes the village of St Ninians, in 1871 was 14,279, and in 1881 it was 16,001.

The town is of unknown antiquity, and undoubtedly owed its origin to the fortress on the rock, which became one of the most important strongholds in Scotland and the centre of the struggle between Scotland and England. As early as 1119 the town was a royal burgh, and under Alexander I it became one of the four towns which constituted the Court of the Four Burghs, superseded under James III by the Convention of Royal Burghs. Its earliest charter was that of Alexander II in 1226, who first made the castle a royal residence. Its last governing charter was obtained from Charles I in 1641. On account of a combination of three members of the council to retain themselves in office it was deprived of its corporate privileges in 1773, and they were not restored till 1781. The castle was held by William the Lion before 1174, was occupied by Edward I with his army in 1296, and was burned with the town in 1298 by the Scots on their retreat from the battle of Falkirk. Between this time and 1341 it was frequently besieged and taken by the English, the longest period during which it remained in their hands being from its capture by Edward I in 1304 till his son's defeat 10 years afterwards at the battle of Bannockburn. It was the birthplace of James II in 1430, and, it being the jointure house of his mother, he was removed to it in 1438 from Edinburgh to thwart the ambitious purposes of Sir William Crichton. It was in one of its rooms that James, as stated above, slew the earl of Douglas, after which the town was burned by the earl's brothers. James V took refuge in it after his escape from Falkland in 1528. During the reign of Mary and the period of the Reformation, Stirling occupied a position of almost as great prominence as during the wars of Scottish independence. Here the infant queen was crowned by the cardinal's party in 1543, here her son, afterwards James VI, was baptized according to the Roman Catholic ritual, 17th December 1566, and here he was crowned by the leaders of the congregation on July 29th of the following year. In 1571 rival parliaments were held by the queen's party in Edinburgh and the king's lords at Stirling, shortly after which an attempt was made by the queen's adherents to surprise Stirling castle, which was almost successful, the regent (Lennox) being slain in the fray. On the 26th April 1578 the castle was surprised by Morton, after which a reconciliation took place between the two parties. In 1584 the castle was occupied by the earls of Angus and Mar, the Protestant leaders, but on the approach of the king with a large force they fled to England. Returning with a formidable army collected in the south in the following year, they compelled James after the flight of Arran to open the gates to them, safety to his person having been guaranteed. The town was the scene of the baptism of Prince Henry with great pomp in August 1594, for which purpose the chapel royal was rebuilt on a larger scale "to entertain the great number of strangers expected." The meetings of the privy council and court of session were held in 1637 at Stirling on account of the disturbed condition of Edinburgh, and a parliament was held at it in 1645, on account of Edinburgh having been visited by the plague, but the outbreak of the disorder in Stirling caused an adjournment to Perth. During the Civil War Stirling was held by the Covenanters, and the committees of church and state adjourned to it after the victory of Cromwell at Dunbar 3d September 1650. In August of the following year the castle was taken by General Monk. In 1715 it was held by Argyll to prevent the passage of the Forth by the Jacobites, and during the rebellion of 1745 it was unsuccessfully besieged by the Highlanders.

STIRLING, EARL OF. See ALEXANDER, SIR WILLIAM, vol. i. p. 493.

STIRLING, JAMES (1692–1770), mathematician, third son of Archibald Stirling of Garden, and grandson of Sir Archibald Stirling of Keir (Lord Garden, a lord of session), was born at Garden, Stirlingshire, in 1692. Part of his early education was probably obtained at Glasgow, but at eighteen years of age he went to Oxford, where, chiefly through the influence of the earl of Mar he was nominated (1711) one of Bishop Warner's exhibitioners at Balliol. During his residence at Oxford he made for himself considerable reputation as a student of mathematics. In 1715, however, he was expelled on account of his correspondence with members of the Keir and Garden families, who were noted Jacobites, and had been accessory to the "Gathering of the Brig of Turk" in 1708. From Oxford he made his way to Venice, where he occupied himself as a professor of mathematics. In 1717 appeared his *Lineæ Tertii Ordinis Newtonianæ, sive* ... (8vo, Oxford), which contained one or two notable additions to the theory. While in Venice, also, he communicated,

through Sir Isaac Newton, to the Royal Society a paper entitled "Methodus Differentialis Newtoniana illustrata" (*Phil Trans*, 1718, p 1050, Abridg, vi p 428) Fearing assassination on account of having discovered a trade secret of the glass-makers of Venice, he returned with Newton's help to London about the year 1725 In London he remained for ten years, being most part of the time connected with an academy in Tower Street, and devoting his leisure to mathematics and correspondence with eminent mathematicians In 1730 his most important work was published, the *Methodus Differentialis, sive Tractatus de Summatione et Interpolatione Serierum Infinitarum* (4to, London), which, it must be noted, is something more than an expansion of the paper of 1718 In 1735 he communicated to the Royal Society a paper "On the Figure of the Earth, and on the Variation of the Force of Gravity at its Surface" (*Phil Trans*, Abridg, viii pp 26–30) In the same year his worldly fortunes changed permanently for the better, through his appointment to be manager for the Scots Mining Company at Leadhills, an appointment which gave scope both to his scientific talents and to his great, though hitherto latent, administrative ability, and which was eminently fortunate for his employers We are thus prepared to find that his next paper to the Royal Society was concerned, not with pure, but with applied science—"Description of a Machine to blow Fire by the Fall of Water" (*Phil Trans*, 1745, p 315, Abridg, ix pp 109, 110) His name is also connected with another practical undertaking since grown to vast dimensions The accounts of the city of Glasgow show that the very first instalment of ten millions sterling spent in making Glasgow a seaport, viz, a sum of £28, 4s 4d, was for a silver tea-kettle to be presented to "James Stirling, mathematician, for his service, pains, and trouble in surveying the river towards deepening it by locks" This was in 1752 Stirling died in Edinburgh on 5th December 1770

See W Fraser, *The Stirlings of Keir, and their Family Papers*, Edinburgh, 1858, "Modern History of Leadhills," in *Gentleman's Magazine*, June 1853, Brewster, *Memoirs of Sir Isaac Newton*, ii pp 300, 307, 411, 516, J Nicol, *Vital Statistics of Glasgow*, 1881–5, p 70, *Glasgow Herald*, 5th August 1886

Another edition of the *Lineæ Tertii Ordinis* was published in Paris in 1797, another edition of the *Methodus Differentialis* in London in 1764, and a translation of the latter into English by Halliday in London in 1749 A considerable collection of literary remains, consisting of papers, letters, and two manuscript volumes of a treatise on weights and measures, are still preserved at Garden by Stirling's great grandson and namesake

STOAT See ERMINE

STOBÆUS, JOANNES, a native of Stobi in Macedonia,—whence the surname Stobæus or Stobensis,—is known to us as the compiler of a very valuable series of extracts from Greek authors Of his life nothing is known, but he probably belongs to the latter half of the 5th century From his silence in regard to Christian authors, it is inferred with some probability that he was not a Christian, that he was a man of wide culture and general reading is clear from the anthology which bears his name

The extracts were intended by Stobæus for his son Septimius, and were preceded by a letter briefly explaining the purpose of the work and giving a summary of the contents From this summary (which is preserved in Photius's *Bibliotheca*) we learn that Stobæus divided his work into four books, the first contained sixty chapters, the second forty-six, the third forty two, and the fourth fifty-eight In most of our MSS the work is divided into three books, of which the first and second are generally called Ἐκλογαὶ φυσικαὶ καὶ ἠθικαί, and the third Ἀνθολόγιον (*Florilegium* or *Sermones*) As each of the four books is sometimes called Ἀνθολόγιον, it is probable that this name originally belonged to the entire work, the full title, as we know from Photius, was Ἐκλογῶν ἀποφθεγμάτων ὑποθηκῶν βιβλία τέτταρα Between the account which Photius gives of Stobæus's work and the form in which we have it there are several marked discrepancies The second book in particular is little more than a fragment From this and other indications Wachsmuth has made it probable that our Stobæus is only an epitome of the original work, made about the end of the 11th century at Byzantium, "ab homine Platonis Aristotelisque amantissimo"

The didactic aim of Stobæus's work is apparent throughout The first book teaches physics—in the wide sense which the Greeks assigned to this term—by means of extracts It is often untrustworthy Stobæus betrays a tendency to confound the dogmas of the early Ionic philosophers, and he occasionally mixes up Platonism with Pythagoreanism For part of this book and much of book ii he depended on the works of Aetius, a Peripatetic philosopher, and Didymus The third and fourth books, like the larger part of the second, treat of ethics, the third, of virtues and vices, in pairs, the fourth, of more general ethical and political subjects, frequently citing extracts to illustrate the pros and cons of a question in two successive chapters In all, Stobæus quotes more than five hundred writers, generally beginning with the poets, and then proceeding to the historians, orators, philosophers, and physicians It is to him that we owe many of our most important fragments of the dramatists, particularly of Euripides

The first complete edition of Stobæus was published at Geneva in 1609, the last is Meineke's (Leipsic, 1855–1864) The best critical edition of books i and ii is by Wachsmuth (Berlin, 1884), a companion edition of books iii and iv (the *Florilegium*) is promised by Otto Hense

STOCK EXCHANGE, a market for the purchase or sale of all descriptions of public securities Previous to 1773 the London stockbrokers conducted their business in and about the Royal Exchange, but in that year, having formed themselves into an association under the designation of the Stock Exchange, they, after temporarily locating their headquarters in Sweeting Ally, Threadneedle Street, removed to Capel Court, Bartholomew Lane The growth of business necessitating improved accommodation, a capital of £20,000 in four hundred shares of £50 each was raised in 1801 for the purpose of erecting a new building in Capel Court, which was finished and occupied in the following year, the members at that date numbering about five hundred With the occupation of the new building new rules came into force, all future members were admitted by ballot, while both members and their authorized clerks were required to pay a subscription of ten guineas each As only the wealthier members of the association had provided the capital for the new building, the Stock Exchange henceforth consisted of two distinct bodies—proprietors and subscribers In 1854, the membership having increased to about one thousand persons, an extension of the premises in Capel Court was effected at a cost of £16,000 A further and very extensive increase in the accommodation was made in 1885, the number of members and authorized clerks having risen at that date to above two thousand five hundred The extended buildings now occupy the whole of a triangle to the east of the Bank of England, having as its base Bartholomew Lane, its north side Throgmorton Street, and its south side portions of Threadneedle Street and Old Broad Street The completed buildings comprise two large halls, where the various markets are held, settlement rooms, reading room, committee rooms, managers' rooms, and various other offices It is intended ultimately to remove the partition between the two halls, when a vast business apartment,

having an area of about 16,000 square feet, will be available for the use of members The immensely valuable property of the Stock Exchange is now owned by about 1050 proprietors, additions both to the proprietary and to the capital invested in the buildings having been from time to time effected during the past fifty years The interests of the proprietors are attended to by nine of their number, who are termed managers, and by a secretary and staff of clerks The income of the association now amounts to about £130,000 per annum, and is derived from the annual subscriptions of members and their clerks, from entrance fees paid by new members, and from rents and investments All members of the Stock Exchange are not proprietors, neither are all proprietors necessarily members Admission as a member is open to any person not engaged in another business He must, however, be recommended by three members, who each guarantee to the committee of the house payment of £750 in the event of the new member being declared a defaulter within two years of his election A personal guarantee of this description is imperative, the object being to exclude all persons of doubtful character Elections are by ballot, and for one year only, all members being theoretically liable to exclusion at the expiry of that period

The stock exchange opens every morning at 11 o'clock and closes at 4, except on Saturday, on which day the doors are shut at 2 o'clock All members of the house are either jobbers or brokers, the former term being applied to those who are dealers in stocks It is contrary to the etiquette of the London Stock Exchange for brokers to deal with brokers, and all transactions are accordingly effected between brokers (representing their clients) and jobbers Brokers' charges vary from one-sixteenth to as much as one-half per cent, and the jobbers' "turn" or profit from one-eighth to two or three per cent, according to the character of the stock dealt in The turn of the jobber amounts in the aggregate to an enormous tax upon the British public, and the question of the utility of this intermediary has been much discussed at various times On buyers and sellers the tax operates in this way —A wishes to buy and B wishes to sell £1000 of Caledonian Railway stock, but, brokers being forbidden to deal with brokers, recourse is had to the jobber C, who makes a price to the brokers of say 98 to 98¼, that is to say, he offers to buy at 98 or to sell at 98¼, the buyer A accordingly pays 98¼ plus his broker's commission, and the seller B receives 98 minus his broker's commission, the jobber C pocketing the difference or "turn" of ¼ per cent The argument in favour of the jobber is that he supplies at all times and in all circumstances a ready market, and it must be allowed that in ordinary times he is a very convenient functionary But, as a matter of fact, in excited times the system often breaks down, as the jobbers frequently shut their books and refuse to deal at the very moment when their help is most needed What are known as the "markets" in the stock exchange are simply groups of jobbers distributed here and there on the floor of the house Habit or convenience seems to have determined the particular spots occupied, which are known as the consol market, the English railway market, the foreign stock market, and so on

In active times the business transacted daily on the London stock exchange amounts to an enormous total Yet no written contracts or notes pass between jobbers and brokers, verbal communications being alone in use Notwithstanding this apparent looseness of practice where millions of property are bought and sold almost hourly, there is hardly a single instance of attempted repudiation on record All transactions are entered into for the fortnightly settlements, the precise dates for which are always fixed a few weeks in advance by the committee of the house Each fortnightly settlement includes three days the first is the continuation or contango day, when all transactions of a merely speculative description are continued for another fortnight, the second the ticket day, when names are passed for actual purchases or sales, and the third the pay day, when all amounts or balances are paid or received As the great bulk of business is purely speculative, the contango or continuation day is by far the busiest of the entire fortnight The floor of the house is then crowded with an eager throng of from 2000 to 3000 brokers, jobbers, and clerks, and during the greater part of the day little is done beyond arranging the account Continuation rates or contangos vary with the value of money and the state of the account When money is dear, or speculative buying active, rates are high, but when speculative selling has preponderated, and the account has become what is called a "bear" account, rates are light An enormous amount of capital is engaged in stock exchange speculation in London Banks, financial companies, and private firms and individuals lend freely on stock exchange securities, and thus encourage, if they do not initiate, most of the great speculative movements Besides the great central institution in London, stock exchanges exist in nearly all the large cities of the United Kingdom The principal are those of Glasgow, Liverpool, and Manchester, which provide excellent markets for local stocks and shares

On the Continent the two chief centres for the transaction of stock exchange business are Paris and Berlin In Paris the business can be traced back for about five hundred years, but it was not until 1726 that the Bourse was legally recognized, sixty *agents de change* for the transaction of business being appointed in that year by the king The Bourse now consists of two distinct bodies, known as the *parquet* and the *coulisse* The *parquet* is composed of the sixty official brokers or *agents de change* appointed by the Government, who alone are admitted to the inner business ring of the Bourse The *coulisse* are the outside dealers or brokers, but, unlike the same class in London, these comprise firms of solid standing, bankers, and arbitrage houses Although a partial settlement occurs once a fortnight, the great bulk of the business on the Paris Bourse is settled for once a month, the arrangements connected therewith occupying no less than six days Another peculiarity in the mode of conducting business in Paris is that sellers can be compelled to deliver stock at any time during the currency of the account At Berlin the Bourse is not under Government control, and although a certain number of licences are issued any one may act as a broker The Bourse can be used by the public on payment of an annual subscription, and all debts incurred there are as obligatory in law as ordinary commercial debts The settlement occupies three days, and occurs at the end of each month

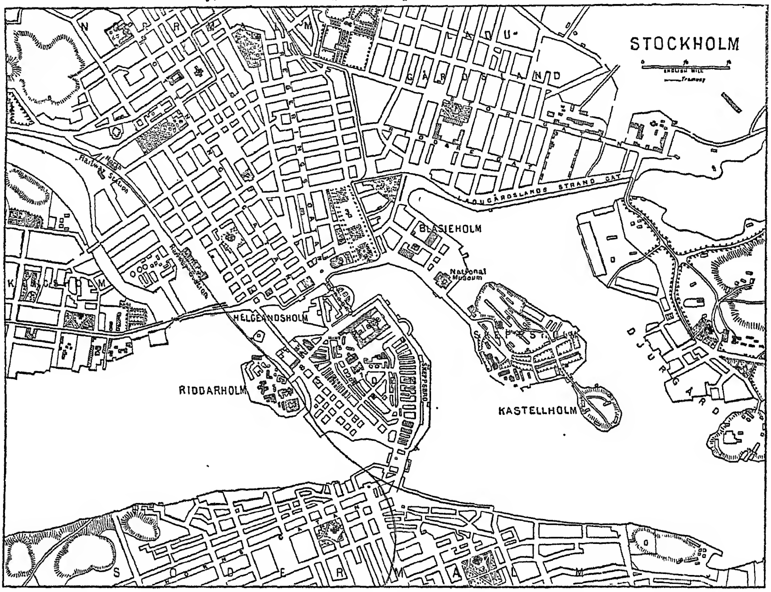
Although stock exchange business in the United States has now attained enormous proportions, it is of comparatively recent origin The first organization of brokers in New York dates from about 1820 The mode of conducting business in Wall Street differs in some respects from both the English and the Continental procedure Transactions entered into on one day are settled on the following, and the full amounts involved, and not the mere differences, are paid and received The jobber, who is of so much importance under the English system, is unknown in New York, as in all cases brokers deal direct with brokers While stock exchange business in London is of immense variety, and comprises all descriptions of home and foreign Government bonds, railway stocks, and miscellaneous shares, in New York it is confined almost entirely to American railway bonds and shares In these securities, however, the volume of business in active times is enormous, the vast railway system of the United States providing an ample choice for the investor and a wide field for speculative manipulation (W P H)

STOCKHOLM, the capital of Sweden, is situated at the point where Lake Malar mixes its waters with those of the Baltic, and at the meeting-place of two provinces, Upland and Sodermanland The old cities of Sweden are regularly found in places where in early times the inhabitants of neighbouring districts came together for purposes of exchange or sometimes of worship, or where a river brought the interior of the country into closer connexion with the coast By the passages that wind among the numerous isles off Stockholm ships at an early date came to the mouth of the lake, only to continue their voyage into its

remoter parts. The two provinces mentioned were densely peopled, and the cultivated regions extended to the mouth of the lake, as is shown by groups of tumuli still to be seen in the immediate neighbourhood of the present city. Still Stockholm does not rank among the oldest cities of Sweden; the exceedingly eligible site had long been neglected owing to its exposure to the incursions of pirates.[1]

Environs of Stockholm.

Stockholm was first founded by Birger Jarl, it is said, in the middle of the 13th century, at a time when pirate fleets were less common than they had been, and the Government was anxious to establish commercial relations with the towns which were now beginning to flourish on the southern coast of the Baltic. The city was originally founded as a fortress on an island at the mouth of Lake Mälar; this island, which is not large, consists of a hill of gravel resting upon rocky ground, having its highest side towards the north, and sloping in the other directions. The castle was erected on the north-eastern corner, and the city was surrounded with walls having fortified towers on the north and south. It came to be called Stockholm ("the isle of the log," Lat. *Holmia*, Germ. *Holm*); the true explanation of the name is not known. Soon the space



1. Church of St John. 2. Humlegård. | 3. Kungsträdgård. 4. Carl XII. Torg. | 5. Mint. 6. Church of St Nicholas. | 7. Stortorg. 8. Riddarhustorg. | 9. Birger Jarls Torg.

which had been enclosed was found to be insufficient, and houses were built outside the walls, which thus lost their defensive character. The castle, two towers belonging to the older works, and some newer walls nearer the water became the sole fortifications. The citizens began also to build on the neighbouring shores, though there, in the event of a siege, all houses had to be destroyed, so as not to give shelter to the enemy. A tendency to increased development has steadily showed itself throughout the Middle Ages and in modern times. On an islet in the stream, between the original Stockholm and the northern shore, was founded, in the 14th century, a hospital of the Holy Ghost, and a new tower was erected to defend the approach to the city. On another islet closely adjoining the original Stockholm on the west, a Franciscan monastery was founded towards the end of the 13th century.

The present city has an area of 12·6 square miles (·44 being water); its extreme length from north to south is about 3·8 miles and its circumference 14¼. The different parts of the actual city are the following. (1) *Staden* is the old "city"; its ancient origin is apparent in the narrow and winding streets. The individual houses are not very old, owing to the ravages of frequent fires; still, some are to be seen with very narrow frontage and gables turned towards the street, as in North Germany. The old market, still called Stortorget ("the great market"), is now one of the smallest in Stockholm. The royal palace, dating from the Middle Ages, but enlarged and partly rebuilt at a later

[1] Before the rise of Stockholm Björkö, Sigtuna, and Upsala were places of great importance. Björkö ("the isle of birches"), by foreign authors called Birca, was a kind of capital where the king lived occasionally at least; history speaks of its relations with Dorestad in the Netherlands, and the extensive refuse heaps of the old city, as well as the numerous sepulchral monuments, show that the population must have been large. But, though situated at a central point on the Mälar Lake, it was destroyed, apparently before the beginning of the 11th century, we do not exactly know when nor by whom; and, once destroyed, it never recovered. Sigtuna, lying on the shore of a far-reaching northern arm of Lake Mälar, also a royal residence and the seat of the first mint in Sweden, where English workmen were employed by King Olaf at the beginning of the 11th century, was, though much more sheltered than Björkö, destroyed in the course of the 12th century.

period, was destroyed by fire in 1697, the body of Charles XI being with difficulty rescued from the flames A new palace, after plans by Nicodemus Tessin, was not completed (owing to wars and the general distress) until 1754 it is a quadrangular structure on the summit of the hill, with two wings towards the east and four towards the west (two straight and two in a semicircle) The style of the building is noble and refined, the royal apartments rich in treasures of art In the immediate vicinity of the palace is the church of St Nicholas, the oldest in Stockholm, but in many parts changed from what it was, the chancel was demolished in the 16th century to give more room for the palace Staden is the commercial centre of the city, containing the exchange, the bank of Sweden, and the custom-house, as well as the offices of many merchants On the eastern side a very large quay, called the Skeppsbro ("the bridge of ships"), extends from the statue of Gustavus III opposite the palace to where the traffic between Lake Malar and the Baltic is carried on through a sluice or lock The Skeppsbro is the landing-place for steamers to the northern provinces of Sweden and foreign ports On the other side of the palace is the Kanslihus, containing the offices of most of the ministries, and a little farther on is a market, named from the palace on its northern side, the Riddarhus, belonging to the Swedish nobility The principal hall of the Riddarhus has its walls adorned with the armorial bearings of the noble families of Sweden The representatives of these families meet here every third year for consultation as to their common interests In front of the building stands the statue of Gustavus I The town-hall stands in the same square (2) *Riddarholmen* contains the old Franciscan church, which, however, is not now used for divine service Since the time of Gustavus Adolphus it has been the burial-place of the royal family, it also contains many trophies from the European wars of Sweden On one side of the church stand the houses of parliament, on the other is the statue of Birger Jarl, the founder of Stockholm A large part of the island is occupied by Government offices, including the record office Along the shore most of the steamers for different parts of Lake Malar and farther on through the canal of Sodertelge, for the Baltic, have their landing-places (3) *Helgeandsholmen* ("the isle of the Holy Ghost") is at present occupied by the royal stables The Norrbro ("north bridge"), connecting the old town with the northern shore, passes the eastern extremity of the island (4) *Norrmalmen* ("the northern suburb") begins at the Norrbro with the market of Gustavus Adolphus, where his statue stands between the theatre royal and the crown prince's palace Norrmalmen is one of the best-built parts of the city, with broad straight streets, it contains four parish churches and also the English church, the Roman Catholic church, and the Jewish synagogue In the south-eastern corner is a large open space, Kungstradgården ("the royal garden"), with the statues of Charles XII and Charles XIII and a fountain, one of the principal playgrounds for children Near it is another park, with the statue of Berzelius Norrmalmen has several public buildings, such as the post-office, the principal railway station, the academy of art, the academy of sciences, the high technical school, and the school of metallurgy, the technical school, the observatory, &c On the northern side of Norrmalmen lies the principal cemetery (5) *Blasieholmen*, united with Norrmalmen since the filling up of the canal which formerly separated them, contains the national museum, the academy of music, &c (6) *Skeppsholmen* ("the isle of ships") and (7) *Castellholmen* both belong to the admiralty (8) *Kungsholmen* ("the isle of the king"), to the west of Norrmalmen, contains a parish church, the mint, the high school of medicine, several hospitals, and many factories (9) *Ladugardslandet* takes its name from the farm yard (*ladugård*) of the royal castle, which formerly occupied a great part of its area It became a part of the city in the middle of the 17th century, but until recently played a very subordinate part, owing to want of water Since the introduction of the new water-supply this part of Stockholm has grown wonderfully, and is now the finest part of the city, with more than 40 000 inhabitants It has a fine park, Humlegården ("hop garden"), with the royal library and the statue of Linnæus Most of the barracks of Stockholm, as well as the high military school, are situated in this quarter of the town (10) *Djurgården* ("deer garden") is a royal park, with villas, restaurants, shipbuilding yards, &c (11) *Sodermalmen* ("the southern suburb") is separated from Staden by the sluice already mentioned On an open space at the side of the channel stands the statue of Charles XIV (Bernadotte) The larger part of this suburb, with its two parish churches, chapels, hospitals, &c, stands at a considerable elevation, and communication has been facilitated by the construction of two elevators On the outskirts are factories, foundries, &c

A glance at the map at once shows how important have been its water facilities in forming the character of Stockholm From all sides the water permeates the different parts of the city, separating them, yet at the same time helping to unite them Stretching far away to east and to west between shores and islands sometimes open and cultivated, sometimes rocky and covered with trees, the water entices the inhabitants to make excursions and to reside for a part of the year in the country, in the summer the city is largely deserted The site is universally recognized as extremely picturesque The great water-surface has also a beneficent influence upon the climate In 1884 the mean temperature was 42° 47 Fahr, the highest temperature of the year being 72° 4 Fahr (2nd and 5th July), the lowest −0° 4 Fahr (30th November) The year's rainfall amounted to 18 3 inches, the number of rainy days being 129 The best time for visiting Stockholm is the latter half of June, when the evening and morning lights, reflected from the water and seen through the young and luxuriant verdure, produce singularly beautiful and varied effects

In Sweden the cities formerly played a comparatively subordinate part During the Swedish Middle Ages the prominent classes were the nobility, the clergy, and the peasantry The anti-aristocratic revolution of the 14th and the 15th centuries had in Sweden its principal supporters among the peasants But the importance of the cities has gradually increased, and recent times have witnessed an accelerated development, which is best exemplified by the history of Stockholm The number of inhabitants was, in 1800, 75,517, in 1825, 79,473, in 1850, 93,070, in 1860, 112,391, in 1870, 136,016, in 1880, 168,775, in 1884, 205,123, and in December 1885, 215,688 In 1884 11,916 were qualified to take part in the election of members of the lower house of parliament Along with the rapid increase of population went a correspondingly increased industrial activity and a considerable development in the means of communication The number of mechanics in 1884 was 11,064 (8716 of the wage earning class), the corresponding numbers for 1880 being 9664 and 7483 The number of factories in 1884 was 275, employing 9810 workpeople (including 2638 women), and producing to the value of 32,355,565 Swedish crowns (£1,797,531) The merchants in 1884 numbered 3828, with 6554 assistants In the same year 37,561 vessels entered (21,460 steamers), while 37,699 (21,565 steamers) cleared Of these 1688 entered from and 1159 cleared for foreign ports In former times Stockholm had the command of all the foreign commerce for the country round Lake Malar, and for the whole of northern Sweden, but more recently the northern cities have made themselves to a certain extent independent of the capital

For communication between the different parts of Stockholm omnibuses and small rowing boats have now given place to small steamers, in 1884 sixty-three of these were in use in the city and its immediate vicinity In 1880 tramways were constructed for Staden, Norrmalmen, Kungsholmen, and Ladugårdslandet

The city forms a separate administrative district under a governor (*ofverstathallare*) In ecclesiastical matters it belongs to the archbishopric of Upsala, and the archbishop has the right to preside in its consistory, of which the president generally is the *pastor primarius*, the rector of St Nicholas The members of this consistory are the rectors of the other seven territorial parishes and the rectors of the Finnish and German congregations There is also a court consistory, presided over by the chief court preacher

It was not until modern times that Stockholm became the capital of Sweden The mediæval kings visited year by year

different parts of the kingdom, where they lived for a shorter or longer time When, from the development of state affairs, the need of a capital came to be felt, no city could compete with the claims of Stockholm It is the usual residence of the king, in the summer he lives generally in one of the palaces in the neighbourhood, some part of every year he passes in his Norwegian capital The supreme court of justice has its seat in Stockholm, as well as the *Svea Hofratt*, the next highest tribunal for central and northern Sweden It is also the seat of all the other central governmental boards

Stockholm is also the seat of seven academies (1) The Swedish Academy, with eighteen members, founded in 1786, deals with the language and literature of Sweden It is engaged upon a Swedish dictionary, and celebrates every year the memory of some renowned Swede (2) The academy of sciences, founded in 1739, with 100 ordinary members, distributed into nine classes, and 75 foreign members, has charge of the royal museum of natural history, the physical, astronomical, and meteorological institutes, and the botanical garden (3) The academy of belles lettres, history, and antiquities, founded in 1753, reformed in 1786, now occupies itself only with history and antiquities, it has 14 honorary members, 20 ordinary members, 16 foreign members and correspondents The secretary of this academy is, at the same time, as royal antiquary of Sweden and garde des médailles, director of the archæological, historical, and numismatical state collections, and inspector of the antiquities of the kingdom (4) The academy of agriculture, founded in 1811, with 24 honorary members, 136 ordinary and 75 foreign members, occupies itself with agriculture and fisheries It has an experimental institution for agricultural chemistry, physiology of plants, gardening, and practical agriculture (5) The academy of fine arts, founded in 1735, has charge of the official school of art (6) The academy of music, founded in 1771, has the care of the state conservatory of music (7) The academy of military sciences was founded in 1796 Each of these academies is a distinct body, most of them publish their transactions, and each has its own library

There are several private societies of a scientific character, such as the society for publication of historical documents, the historical society, the society of anthropology and geography, the society of national antiquities, the geological society, the society of natural sciences, the entomological society, &c

Stockholm has no state university, but there is a high school of medicine (*Carolinska Institute*), which has several professors of mathematics and natural science The city has also a high technical school, a technical school, a high military school, and a military school (in the palace of Carlberg, outside of the city), a veterinary school, a school of pharmacy, seven more or less complete secondary schools, and two seminaries for female teachers, besides private schools The number of pupils in the secondary schools in 1884 was 2294 and in the primary schools 14,351

The following are the principal public collections (1) The royal historical museum (in the national museum) contains a remarkably rich series of the prehistoric antiquities of the country Founded in the 17th century, it has made greatest progress since 1837 (2) The royal numismatical collection (in the national museum) contains about 90,000 coins and medals The series of Anglo-Saxon coins found in Sweden is very important (3) The numismatical collection of the Bank of Sweden (in the bank offices) contains very good series of Swedish coins and medals (4) The royal collection of armour and royal dresses (in the royal palace) is very rich in specimens of the 17th and 18th centuries (5) The royal museum of fine and industrial arts (in the national museum) contains sculptures, pictures, engravings, drawings, &c The collection of Swedish art is, of course, very rich Of foreign schools that of the Netherlands is best represented The collection illustrating the development of industrial arts consists principally of gifts of Charles XV and Count A Bjelke (6) The royal museum of natural history (in the palace of the academy of sciences), with very rich zoological, botanical, palæontological, and mineral series, is exceedingly rich in objects from the arctic regions Other collections deserving mention are (7) the museum of the geological survey of Sweden, (8) the museum of the school of medicine, (9) the northern museum, a private institution, a very rich collection representing the life of all social classes of the north, (10) the royal library, very rich in books and manuscripts, and (11) the royal archives

STOCKINGS See HOSIERY

STOCKPORT, a market-town and municipal and parliamentary borough of England, in Cheshire and partly in Lancashire, is situated on an elevation above the Mersey at the junction of the Tame and Goyt, and of a number of railway lines, 46 miles east-north east of Chester, 37 east of Liverpool, and 6 south-south-east of Manchester Owing to the lie of the ground the streets are very irregular and uneven, and occasionally precipitous, while in the south they rise above the river in tiers The Mersey is crossed by a number of bridges, including one of eleven arches opened in 1826 at a cost of £40,000 None of the ecclesiastical buildings are of special interest, the principal being the church of St Mary, erected in 1817, at a cost of £30,000, on the site of one of the 15th century, of which the chancel and vestry remain The free grammar school was founded and endowed in 1487 by Sir Edward Shaa or Shaw, knight The present building was erected in 1831 by the Goldsmiths' Company, who further endowed it with £290 a year, and handed it over to the corporation The Stockport Sunday school, erected in 1805, has accommodation for 4000 scholars There is a free public library, established in 1875 The principal public buildings are the court-house, the market-house, the union workhouse, the mechanics' institute, the infirmary, the institution for the blind and deaf and dumb, and the fine new public baths In St Peter's Square there is a statue, unveiled 27th November 1886, of Richard Cobden, who was elected member for the borough in 1841 and 1847 Vernon Park, finely situated about a mile from the town, contains a free museum, built in 1858 at the expense of the members for the borough, and since enlarged by the corporation The staple industries are the spinning and weaving of cotton and felt-hat making There are also breweries, foundries, machine-works, and flour-mills The limits of the municipal and parliamentary boroughs are co extensive The area is 2200 acres, with a population in 1871 of 53,014 and in 1881 of 59,553

Though not referred to in any of the Roman itineraries, and possessing neither Roman nor Saxon remains, Stockport is supposed to have been a Roman camp or outpost, which occupied the hill on which the Normans afterwards built a baronial castle It is not mentioned in Domesday The castle was held in 1173 by Geoffrey de Costentyn against Henry II, but whether in his own right or not is uncertain In the beginning of the 13th century it was possessed by the first Baron Ranulf de Dapifer, progenitor of the Despensers, from whom it passed to Robert de Stockeport, who in the reign of Henry III made the town a free borough, and in 1260 received for it from the earl of Chester the grant of a market The town was visited by the plague in 1605-6 It was of some importance during the Civil War, and was taken by the Royalists under Prince Rupert in May 1644 During the insurrection of 1745 Prince Charles Edward rested at the town on the 28th November The town was enfranchised in 1832, with the right, which it still retains, of returning two members, and was incorporated under the *Corporations Act* in 1835

STOCKS, as a form of punishment, are now quite obsolete They were originally established in England after the passing of the Statute of Labourers, 23 Edw III c 1 That Act enjoined that stocks (*ceppes*) should be made in every town between the passing of the Act and Pentecost of that year (1350) By numerous other statutes, until comparatively modern times, the punishment of the stocks was inflicted for offences of a less heinous kind, *e g*, breaches of the Sunday Observance Acts of Charles I and Charles II In the United States the stocks were formerly used as a means of punishing slaves

STOCKTON, a city of the United States, county seat of San Joaquin county, California, at the head of the Stockton navigable channel which joins the San Joaquin river, and 48 miles south-south-east of Sacramento, by the western division of the Central Pacific Railroad. It is the business centre of the San Joaquin valley, a great wheat market, and the seat of the State lunatic asylum (founded in 1853) Artesian wells 80 to 1000 feet deep provide the city with a perennial supply of water Two public libraries, several public schools, and a convent may be mentioned among its important institutions, and it manufactures leather, agricultural implements, paper, flour, &c The population was 10,066 in 1870 and 10,282 in

1880 Stockton was laid out in 1849, and was incorporated as a city in 1850

STOCKTON-ON-TEES, a market-town and municipal and parliamentary borough and seaport of Durham, on the borders of the North Riding of Yorkshire, into which the parliamentary borough extends, is situated on the Tees, which is crossed by an iron bridge (completed in 1887 at a cost over £80,000, to supersede the stone bridge of 1769) leading to South Stockton, and on the Stockton and Darlington and the Sunderland and West Hartlepool branches of the North-Eastern Railway, 20 miles south-south-east of Durham, and 4 miles west-south-west of Middlesborough The principal street is about a mile in length Of the ancient castle commanding the Tees, which was destroyed in 1652, the last remains were removed in 1865 Among the principal public buildings are the town-hall, with a clock-tower and spire, the borough hall (erected in 1852 at a cost of £32,000), the freemasons' hall, the temperance hall, the theatre, the exchange hall, the literary institute, the hospital, the dispensary, the free library, and the blue-coat school Stockton is a seaport of considerable importance The management of the Tees, vested in 1808 in the Tees Navigation Company, was in 1852 vested in the Tees Conservancy Commissioners, incorporated by Act of Parliament, under whose auspices the river has been greatly improved The trade of the port is chiefly with Holland and the ports of the Baltic, and there is a considerable coasting trade with the Tyne ports and with Hull and London Its chief exports are iron manufactures, coal, coke, and agricultural produce, the average annual value for the five years 1880–84 being about £72,000 The principal imports are timber, iron, grain, and provisions, the average annual value for the five years 1880–84 being about £240,000 In 1885 the number of vessels that entered the port was 649, of 149,628 tons, the number that cleared 700, of 175,647 tons The rapid increase of the town within the last quarter of a century is largely owing to the development of the iron and steel trade in the district There are extensive steel works, blast-furnaces, iron and brass foundries and rolling-mills, and iron-shipbuilding is also an important industry There are also sailcloth works, potteries, breweries, and brick and tile works The population of the municipal borough (area 1189 acres) in 1871 was 27,738, and in 1881 it was 41,015 The population of the parliamentary borough (area 7157 acres) in the same years was 37,612 and 55,457 The parliamentary borough includes the suburb of South Stockton on the opposite side of the river, forming a separate urban sanitary district (area 1052 acres), with a population in 1871 of 6794 and in 1881 of 10,665 It has a temperance hall, a mechanics' institute, and a national school, and its manufactures are similar to those of Stockton

The place is of great antiquity, and is supposed to have been occupied by the Romans Before the Conquest the manor belonged to the see of Durham It was probably first incorporated by Bishop Hugh de Pudsey, who in the reign of Richard I occupied the castle The castle, which was for a long time the residence of the bishops, stood on the north bank of the Tees The town was destroyed by the Scots in 1322, but the castle seems to have escaped During the Civil War it was garrisoned for the king, but was afterwards delivered up to the Parliamentary party, and in 1645 was held by the Scots The town suffered severely from inundations of the Tees in 1771, 1783, and 1822 Though Stockton was placed under the Municipal Act of 1835 it remained divided into two parts, the one called the "borough," where the land was freehold, governed by the corporation, and the other called the "town," where the land was copyhold or leasehold, held under the vicar and vestrymen, and outside the corporate jurisdiction To remedy this state of matters an "Extension and Improvement Act" was passed in 1852 The town was enfranchised in 1867, and returns one member

STOICS, a school of philosophers founded at the close of the 4th century B C by Zeno of Citium, and so called from the Stoa or painted corridor (στοὰ ποικίλη) on the north side of the market-place at Athens, which, after its restoration by Cimon, the celebrated painter Polygnotus had adorned with frescos representing scenes from the Trojan War But, though it arose on Hellenic soil, from lectures delivered in a public place at Athens, the school is scarcely to be considered a product of purely Greek intellect, but rather as the firstfruits of that interaction between West and East which followed the conquests of Alexander Hardly a single Stoic of eminence was a citizen of any city in the heart of Greece, unless we make Aristo of Chios, Cleanthes of Assus, and Panætius of Rhodes exceptions Such lands as Cyprus, Cilicia, and Syria, such cities as Citium, Soli, Heraclea in Pontus, Sidon, Carthage, Seleucia on the Tigris, Apamea by the Orontes, furnished the school with its scholars and presidents, Tarsus, Rhodes, and Alexandria became famous as its university towns As the first founder was of Phœnician descent, so he drew most of his adherents from the countries which were the seat of Hellenistic (as distinct from Hellenic) civilization, nor did Stoicism achieve its crowning triumph until it was brought to Rome, where the grave earnestness of the national character could appreciate its doctrine, and where for two centuries or more it was the creed, if not the philosophy, of all the best of the Romans Properly therefore it stands in marked antithesis to that fairest growth of old Hellas, the Academy, which saw the Stoa rise and fall,—the one the typical school of Greece and Greek intellect, the other of the Hellenized East, and, under the early Roman empire, of the whole civilized world The transcendent genius of its author, the vitality and romantic fortunes of his doctrine, claim our warmest sympathies for Platonism But it should not be forgotten that for more than four centuries the tide ran all the other way It was Stoicism, not Platonism, that filled men's imaginations, and exerted the wider and more active influence upon the ancient world at some of the busiest and most important times in all history And this was chiefly because before all things it was a practical philosophy, a rallying point for strong and noble spirits contending against odds Nevertheless, in some departments of theory, too, and notably in ethics and jurisprudence, Stoicism has dominated the thought of after ages to a degree not easy to exaggerate

The history of the Stoic school may conveniently be divided in the usual threefold manner the old Stoa, the middle or transition period (Diogenes of Seleucia, Boethus of Sidon, Panætius, Posidonius), and the later Stoicism of Roman times By the old Stoa is meant the period (*c* 304–205 B C) down to the death of Chrysippus, the second founder, then was laid the foundation of theory, to which hardly anything of importance was afterwards added Confined almost to Athens, the school made its way slowly among many rivals Aristo of Chios and Herillus of Carthage, Zeno's heterodox pupils, Persæus, his favourite disciple and housemate, the poet Aratus, and Sphærus, the adviser of the Spartan king Cleomenes, are noteworthy minor names, but the chief interest centres about Zeno, Cleanthes, Chrysippus, who in succession built up the wondrous system What originality it had—at first sight it would seem not much—belongs to these thinkers, but the loss of all their works except the hymn of Cleanthes, and the inconsistencies in such scraps of information as can be gleaned from unintelligent witnesses, for the most part of many centuries later, have rendered it a peculiarly difficult task to distinguish with certainty the work of each of the three The common standpoint, the relation to contemporary or earlier systems, with all that goes to make up the character and spirit of Stoicism, can, fortunately, be more certainly established, and may with reason be attributed to the founder Zeno's residence at Athens

Zeno fell at a time when the great movement which Socrates originated had spent itself in the second generation of his spiritual descendants Neither Theophrastus at the Lyceum, nor Xenocrates and Polemo at the Academy, nor Stilpo, who was drawing crowds to hear him at Megara, could be said to have inherited much of the great reformer's intellectual vigour, to say nothing of his moral earnestness Zeno visited all the schools in turn, but seems to have attached himself definitely to the Cynics, as a Cynic he composed at least one of his more important works, "the much admired *Republic*," which we know to have been later on a stumbling-block to the school In the Cynic school he found the practical spirit which he divined to be the great need of that stirring troublous age For a while his motto must have been "back to Socrates," or at least "back to Antisthenes" The Stoics always counted themselves amongst the Socratic schools, and canonized Antisthenes and Diogenes, while reverence for Socrates was the tie which united to them such an accomplished writer upon lighter ethical topics as the versatile Persæus, who at the capital of Antigonus Gonatas, with hardly anything of the professional philosopher about him, reminds us of Xenophon, or even Prodicus Zeno commenced, then, as a Cynic, and in the developed system we can point to a kernel of Cynic doctrine to which various philosophemes of other thinkers (more especially Heraclitus and Aristotle, but also Diogenes of Apollonia, the Pythagoreans, and the medical school of Hippocrates in a lesser degree) were added Thus, quite apart from the general similarity of their ethical doctrine, the Cynics were materialists, they were also nominalists, and combated the Platonic ideas, in their theory of knowledge they made use of "reason" (λόγος), which was also one of their leading ethical conceptions In all these particulars Zeno followed them, and the last is the more important, because, Chrysippus having adopted a new criterion of truth,—a clear and distinct perception of sense,—it is only from casual notices we learn that the elder Stoics had approximated to Cynicism in making right reason the standard At the same time, it is certain that the main outlines of the characteristic physical doctrine, which is after all the foundation of their ethics and logic, were the work of Zeno The Logos, which had been an ethical or psychological principle to the Cynics, received at his hands an extension throughout the natural world, in which Heraclitean influence is unmistakable Reading the Ephesian doctrine with the eyes of a Cynic, and the Cynic ethics in the light of Heracliteanism, he came to formulate his distinctive theory of the universe far in advance of either In taking this immense stride and identifying the Cynic "reason," which is a law for man, with the "reason" which is the law of the universe, Zeno has been compared with Plato, who similarly extended the Socratic "general notion" from the region of morals,—of justice, temperance, virtue,—to embrace all objects of all thought, the verity of all things that are If the recognition of physics and logic as two studies co ordinate with ethics is sufficient to differentiate the mature Zeno from the Cynic author of the *Republic*, no less than from his own heterodox disciple Aristo, the elaboration on all sides of Stoic natural philo-

Cleanthes sophy belongs to Cleanthes, who certainly was not the merely docile and receptive intelligence he is sometimes represented as being He carried on and completed the assimilation of Heraclitean doctrine, but his own contributions were more distinctive and original than those of any other Stoic Zeno's seeming dualism of God (or force) and formless matter he was able to transform into the lofty pantheism which breathes in every line of the famous hymn to Zeus. Heraclitus had indeed declared all to be in flux, but we ask in vain what is the cause for the unceasing process of his ever-living fire It was left for Cleanthes to discover this motive cause in a conception familiar to Zeno, as to the Cynics before him, but restricted to the region of ethics,—the conception of tension or effort. The soul of the sage, thought the Cynics, should be strained and braced for judgment and action, his first need is firmness (εὐτονία) and Socratic strength But the mind is a corporeal thing Then followed the flash of genius this varying tension of the one substance everywhere present, a purely physical fact, accounts for the diverse destinies of all innumerable particular things, it is the veritable cause of the flux and process of the universe Herein lies the key to the entire system of the Stoics, as Cleanthes's epoch-making discovery continually received fresh applications to physics, ethics, and epistemology Other of his innovations, the outcome of his crude materialism, found less favour with his successor, who declined to follow him in identifying the primary substance with fire, or in tracing all vitality to its ultimate source in the sun, the "ruling power" of the world,—a curious anticipation of scientific truth Yet under this poetical Heraclitean mystic the school was far from flourishing The eminent teachers of the time are said to have been Aristo, Zeno's heterodox pupil, and Arcesilas, who in Plato's name brought Megarian subtleties and Pyrrhonian agnosticism to bear upon the intruding doctrine, and after a vigorous upgrowth it seemed not unlikely to die out From all danger of such a fate it was rescued by its third great teacher, Chrysippus, "but for Chrysippus there had been no Porch" Zeno had caught the practical spirit of his age,—the desire for a popular philosophy to meet individual needs But there was another tendency in post-Aristotelian thought,—to lean upon authority and substitute learning for independent research,—which grew stronger just in proportion as the fresh interest in the problems of the universe and the zeal for discovery declined,—a shadow, we may call it, of the coming Scholasticism thrown a thousand years in advance The representative of this tendency, Chrysippus addressed himself to the congenial task of assimilating, developing, systematizing the doctrines bequeathed to him, and, above all, securing them in their stereotyped and final form, not simply from the assaults of the past, but, as after a long and successful career of controversy and polemical authorship he fondly hoped, from all possible attack in the future To his personal characteristics can be traced the hair-splitting and formal pedantry which ever afterwards marked the activity of the school, the dry repellent technical procedure of the Dialecticians *par excellence*, as they were called He created their formal logic and contributed much that was of value to their psychology and epistemology, but in the main his work was to new-label and new arrange in every department, and to lavish most care and attention on the least important parts,—the logical terminology and the refutation of fallacies, or, as his opponents declared, the excogitation of fallacies which even he could not refute In his *Republic* Zeno had gone so far as to declare the routine education of the day (*e g*, mathematics, grammar, &c) to be of no use Such Cynic crudity Chrysippus rightly judged to be out of keeping with the requirements of a great dogmatic school, and he laboured on all sides after thoroughness, erudition, and scientific completeness In short, Chrysippus made the Stoic system what it was, and as he left it we proceed to describe it

Chrysippus

Conception of philosophy. And first we will inquire, What is philosophy? No idle gratification of curiosity, as Aristotle fabled of his life intellectual (which would be but a disguise for refined pleasure), no theory divorced from practice, no pursuit of science for its own sake, but knowledge so far forth as it

can be realized in virtuous action, the learning of virtue by exercise and effort and training. So absolutely is the "rare and priceless wisdom" for which we strive identical with virtue itself that the three main divisions of philosophy current at the time and accepted by Zeno,—logic, physics, and ethics,—are defined as the most generic or comprehensive *virtues*. How otherwise could they claim our attention? Accordingly Aristo, holding to Cynicism when Zeno himself had got beyond it, rejected two of these parts of philosophy as useless and out of reach,—a divergence which excluded him from the school, but strictly consistent with his view that ethics alone is scientific knowledge. Of the three divisions logic is the least important; ethics is the outcome of the whole, and historically the all-important vital element; but the foundations of the whole system are best discerned in the science of nature, which deals pre-eminently with the macrocosm and the microcosm, the universe and man, including natural theology and an anthropology or psychology, the latter forming the direct introduction to ethics.

The Stoic system is in brief—(*a*) materialism, (*b*) dynamic materialism, lastly (*c*) monism or pantheism. (*a*) The first of these characters is described by anticipation in Plato's *Sophist* (246 C *sq*.), where, arguing with those "who drag everything down to the corporeal" (σῶμα), the Eleatic stranger would fain prove to them the existence of something incorporeal, as follows. "They admit the existence of an animate body. Is soul then something existent (οὐσία)? Yes. And the qualities of soul, as justice and wisdom—are they visible and tangible? No. Do they then exist? They are in a dilemma." Now, however effective against Plato's contemporary Cynics or Atomists, the reasoning is thrown away upon the Stoics, who take boldly the one horn of this dilemma. That qualities of bodies (and therefore of the corporeal soul) exist they do not deny; but they assert most uncompromisingly that they are one and all (wisdom, justice, &c.) corporeal. And they strengthen their position by taking Plato's own definition (247 D), namely, "being is that which has the power to act or be acted upon," and turning it against him. For this is only true of Body; action, except by contact, is inconceivable; and they reduce every form of causation to the efficient cause, which implies the communication of motion from one body to another. Again and again, therefore, only Body exists. The most real realities to Plato and Aristotle had been thought and the objects of thought, νοῦς and νοητά, whether abstracted from sensibles or inherent in "matter," as the incognizable basis of all concrete existence. But this was too great an effort to last long. Such spiritualistic theories were nowhere really maintained after Aristotle and outside the circle of his immediate followers. The reaction came and left nothing of it all; for five centuries the dominant tone of the older and the newer schools alike was frankly materialistic. "If," says Aristotle, "there is no other substance but the organic substances of nature, physics will be the highest of the sciences," a conclusion which passed for axiomatic until the rise of Neoplatonism. The analogues therefore of metaphysical problems must be sought in physics; particularly that problem of the causes of things for which the Platonic idea and the Peripatetic "constitutive form" had been in turn received solutions. (*b*) But the doctrine that all existence is confined within the limits of the sensible universe,—that there is no being save corporeal being or body,—does not suffice to characterize the Stoic system; it is no less a doctrine of the Epicureans. It is the idea of tension as the essential attribute of body, in contradistinction to passive inert matter, which is distinctively Stoic. The Epicureans leave unexplained the primary constitution and first movements of their atoms or elemental solids; chance or declination may account for them. Now, to the Stoics nothing passes unexplained; there is a reason (λόγος) for everything in nature. Everything which exists is at once capable of acting and being acted upon. In everything that exists, therefore, even the smallest particle, there are these two principles. By virtue of the passive principle the thing is susceptible of motion and modification; it is matter which determines substance (οὐσία). The active principle makes the matter a given determinate thing, characterizing and qualifying it, whence it is termed quality (ποιότης). For all that is or happens there is an immediate cause or antecedent; and as "cause" means "cause of motion," and only body can act upon body, it follows that this antecedent cause is itself as truly corporeal as the matter upon which it acts. Thus we are led to regard the active principle "force" as everywhere co-extensive with "matter," as pervading and permeating it, and together with it occupying and filling space. This is that famous doctrine of universal permeation (κρᾶσις δι' ὅλου), by which the axiom that two bodies cannot occupy the same space is practically denied. Thus that harmony of separate doctrines which contributes to the impressive simplicity of the Stoic physics is only attained at the cost of offending healthy common sense, for Body itself is robbed of a characteristic attribute. A thing is no longer, as Plato once thought, hot or hard or bright by partaking in abstract heat or hardness or brightness, but by containing within its own substance the material of these qualities, conceived as air-currents in various degrees of tension. We hear, too, of corporeal days and years, corporeal virtues, and actions (like walking) which are bodies (σώματα). Obviously, again, the Stoic quality corresponds to Aristotle's essential form; in both systems the active principle, "the cause of all that matter becomes," is that which accounts for the existence of a given concrete thing (λόγος τῆς οὐσίας). Only here, instead of assuming something immaterial (and therefore unverifiable), we fall back upon a current of air or gas (πνεῦμα); the essential reason of the thing is itself material, standing to it in the relation of a gaseous to a solid body. Here, too, the reason of things—that which accounts for them—is no longer some external end to which they are tending; it is something acting within them, "a spirit deeply interfused," germinating and developing as from a seed in the heart of each separate thing that exists (λόγος σπερματικός). By its prompting the thing grows, develops, and decays, while this "germinal reason," the element of quality in the thing, remains constant through all its changes. (*c*) What then, we ask, is the relation between the active and the passive principles? Is there, or is there not, an essential distinction between substance or matter and pervading force or cause or quality? Here the Stoa shows signs of a development of doctrine. Zeno began, perhaps, by adopting the formulas of the Peripatetics, though no doubt with a conscious difference, postulating that form was always attached to matter, no less than matter, as known to us, is everywhere shaped or informed. Whether he ever overcame the dualism which the sources, such as they are, unanimously ascribe to him is not clearly ascertained. It seems probable that he did not. But we can answer authoritatively that to Cleanthes and Chrysippus, if not to Zeno, there was no real difference between matter and its cause, which is always a corporeal current, and therefore matter, although the finest and subtlest matter. In fact they have reached the final result of unveiled hylozoism, from which the distinction of the active and passive principles is discerned to be a merely formal concession to Aristotle, a legacy from his dualistic doctrine. His technical term Form (εἶδος) they never use, but always Reason or God. This was not the first time

Matter and force.

Monism.

that approaches had been made to such a doctrine, and Diogenes of Apollonia in particular was led to oppose Anaxagoras, who distinguished Nous or Thought from every other agent within the cosmos which is its work, by postulating as his first principle something which should be at once physical substratum and thinking being. But until dualism had been thought out, as in the Peripatetic school, it was impossible that monism (or at any rate materialistic monism) should be definitely and consciously maintained. One thing is certain: the Stoics provided no loophole of escape by entrenching upon the "purely material" nature of matter; they laid down with rigid accuracy its two chief properties,—extension in three dimensions, and resistance, both being traced back to force. There were, it is true, certain inconsistent conceptions, creations of thought to which nothing real and external corresponded, namely, time, space, void, and the idea expressed in language (λεκτόν). But this inconsistency was covered by another: though each of these might be said to be something, they could not be said to exist.

Cosmogony

The distinction of force and matter is then something transitory and relative. Its history will serve as a sketch of the cosmogony of the Stoics, for they too, like earlier philosophers, have their "fairy tale of science." Before there was heaven or earth, there was primitive substance or Pneuma, the everlasting presupposition of particular things. This is the totality of all existence; out of it the whole visible universe proceeds, hereafter to be again resolved into it. Not the less is it the creative force, or deity, which develops and shapes this universal order or cosmos. To the question, What is God? Stoicism rejoins, What is God not? In this original state of Pneuma God and the world are absolutely identical. But even then tension, the essential attribute of matter, is at work. Though the force working everywhere is one, there are diversities of its operation, corresponding to various degrees of tension. In this primitive Pneuma there must reside the utmost tension and heat; for it is a fact of observation that most bodies expand when heated, whence we infer that there is a pressure in heat, an expansive and dispersive tendency. The Pneuma cannot long withstand this intense pressure. Motion backwards and forwards once set up goes to cool the glowing mass of fiery vapour and to weaken the tension. Hereupon follows the first differentiation of primitive substance,—the separation of force from matter, the emanation of the world from God. The germinal world-making powers (σπερματικοὶ λόγοι), which, in virtue of its tension, slumbered in Pneuma, now proceed upon their creative task. The primitive substance, be it remembered, is not Heraclitus's fire (though Cleanthes also called it flame of fire, φλόξ) any more than it is the air or "breath" of Anaximenes or Diogenes of Apollonia. Chrysippus determined it, following Zeno, to be fiery breath or ether, a spiritualized sublimed intermediate element. The cycle of its transformations and successive condensations constitutes the life of the universe, the mode of existence proper to finite and particular being. For the universe and all its parts are only different embodiments and stages in that metamorphosis of primitive being which Heraclitus had called a progress up and down (ὁδὸς ἄνω κάτω). Out of it is separated, first, elemental fire, the fire which we know, which burns and destroys; and this, again, condenses into air or aerial vapour; a further step in the downward path derives water and earth from the solidification of air. At every stage the degree of tension requisite for existence is slackened, and the resulting element approaches more and more to "inert" matter. But, just as one element does not wholly pass over into another (*e.g.*, only a part of air is transmuted into water or earth), so the Pneuma itself does not wholly pass over into the elements. The residue that remains in original purity with its tension yet undiminished is the ether in the highest sphere of the visible heavens, encircling the world of which it is lord and head. From the elements the one substance is transformed into the multitude of individual things in the orderly universe, which again is itself a living thing or being, and the Pneuma pervading it, and conditioning life and growth everywhere, is its soul. But this process of differentiation is not eternal; it continues only until the times of the restoration of all things. For the world which has grown up will in turn decay. The tension which has been relaxed will again be tightened; there will be a gradual resolution of things into elements, and of elements into the primary substance, to be consummated in a general conflagration when once more the world will be absorbed in God. Then in due order a new cycle of development begins, reproducing the last in every minutest detail, and so on for ever.

Pneuma

The doctrine of Pneuma, vital breath or "spirit," arose in the medical schools. The simplest reflexion among savages and half civilized men connects vitality with the air inhaled in respiration; the disciples of Hippocrates, without much modifying this primitive belief, explained the maintenance of vital warmth to be the function of the breath within the organism. In the time of Alexander the Great Praxagoras discovered the distinction between the arteries and the veins. Now in the corpse the former are empty; hence in the light of these preconceptions they were declared to be vessels for conveying Pneuma to the different parts of the body. A generation afterwards Erasistratus made this the basis of a new theory of diseases and their treatment. Vital spirit, inhaled from the outside air, rushes through the arteries till it reaches the various centres, especially the brain and the heart, and there causes thought and organic movement. But long before this the peculiar character of air had been recognized as something intermediate to the corporeal and the incorporeal: when Diogenes of Apollonia revived the old Ionian hylozoism in opposition to the dualism of Anaxagoras, he made this, the typical example of matter in the gaseous state, his one element. In Stoicism, for the moment, the two conceptions are united, soon, however, to diverge,—the medical conception to receive its final development under Galen, while the philosophical conception, passing over to Philo and others, was shaped and modified at Alexandria under the influence of Judaism, whence it played a great part in the developments of Jewish and Christian theology.

Contrast to Heraclitus

The influence upon Stoicism of Heraclitus has been differently conceived. Siebeck would reduce it within very small dimensions, but this is not borne out by the concise history found at Herculaneum (*Index Herc.*, ed. Comparetti, col. 4 *sq.*). They substituted primitive Pneuma for his primitive fire, but so far as they are hylozoists at all they stand upon the same ground with him. Moreover, the commentaries of Cleanthes, Aristo, and Sphærus on Heraclitean writings (Diog. L., vii. 174, ix. 5, 15) point to common study of these writings under Zeno. Others again (*e.g.*, Lassalle) represent the Stoics as merely diluting and distorting Heracliteanism. But this is altogether wrong, and the proofs offered, when rightly sifted, are often seen to rest upon the distortion of Heraclitean doctrine in the reports of later writers, to assimilate it to the better known but essentially distinct innovations of the Stoics. In Heraclitus the constant flux is a metaphysical notion replaced by the interchange of material elements which Chrysippus stated as a simple proposition of physics. Heraclitus offers no analogy to the doctrine of four (not three) elements as different grades of tension, to the conception of fire and air as the "form," in Aristotelian terminology, of particulars, nor to the function of organizing fire which works by methodic plan to produce and preserve the world (πῦρ τεχνικὸν ὁδῷ βαδίζον ἐπὶ γένεσιν κόσμου). Nor, again, is there any analogy to the peculiar Stoic doctrine of universal intermingling (κρᾶσις δι' ὅλου). The two active elements interpenetrate the two lower or more relaxed, winding through all parts of matter and so pervading the greater masses that there is no mechanical mixture, nor yet a chemical combination, since both "force" and "matter" retain their relative characters as before. Even the distinction between "force" and "matter"—so alien to the spirit of Heraclitus—is seen to be a necessary consequence. Once assume that every character and property of a particular thing is determined solely by the tension in it of a current of Pneuma, and (since that which causes currents in the thing cannot be absolutely the same with the thing itself) Pneuma, though present in all things, must be asserted to vary indefinitely in quantity and intensity. So condensed and coarsened is the indwelling air current of inorganic bodies that no trace of elasticity or life remains; it cannot even afford them the power of motion; all it can do is to hold them together (συνεκτικὴ δύναμις), and, in technical language, Pneuma is present in stone or metal as a retaining principle (ἕξις=hold), explaining the attributes of continuity and numerical identity (συνεχῆ καὶ ἡνωμένα) which even these natural substances possess. In plants again and all the vegetable kingdom it is manifest as something far purer and possessing greater tension, called a "nature," or principle of growth (φύσις). Further, a distinction was drawn between irrational animals, or the brute creation, and the rational, *i.e.*, gods and men, leaving room for a divergence, or rather development, of Stoic opinion. The older authorities conceded a vital principle, but denied a soul, to the brutes: animals, they say, are ζῷα but not ἔμψυχα. Later on much evidence goes to show that (by a divergence from the orthodox standard perhaps due to Platonic influence) it was a Stoic tenet to concede a soul, though not a rational soul, throughout the animal kingdom. To this higher manifestation of Pneuma can be traced back the "esprits animaux" of Descartes and Leibnitz, which continue to play so great a part even in Locke. The universal presence of Pneuma was confirmed by observation. A certain warmth, akin to the vital heat of organic being, seems to be found in inorganic nature: vapours from the earth, hot springs, sparks from the flint, were claimed as the last remnant of Pneuma not yet utterly slackened and cold. They appealed also to the velocity and dilatation of aeriform bodies, to whirlwinds and inflated balloons. The Logos is quick and powerful, and sharper than any two edged sword, piercing even to the

dividing asunder of the joints and marrow. Tension itself Cleanthes defined as a fiery flash (πληγὴ πυρός). Take the fundamental properties of body—extension and resistance. The former results from distance; but distances, or dimensions, are straight lines, *i.e.*, lines of greatest tension (εἰς ἄκρον τεταμένη). Tension produces dilatation, or increase in distance. Resistance, again, is explained by cohesion, which implies binding force. Again, the primary substance has rectilinear motion in two directions, backwards and forwards, at once a condensation, which produces cohesion and substance, and a dilatation, the cause of extension and qualities. How near this comes to the scientific truth of attraction and repulsion need hardly be noted. From the astronomers the Stoics borrowed their picture of the universe,—a *plenum* in the form of a series of layers or concentric rings, first the elements, then the planetary and stellar spheres, massed round the earth as centre,—a picture which dominated the imagination of men from the days of Eudoxus down to those of Dante or even Copernicus. As to the physical constitution of bodies, they were content to reproduce the Peripatetic doctrine with slight modifications in detail, of hardly any importance when compared with the change of spirit in the doctrine taught. But they rarely prosecuted researches in physics or astronomy, and the newly created sciences of biology and comparative anatomy received no adequate recognition from them.

Psychology.

If, however, in the science of nature the Stoics can lay claim to no striking originality, the case is different when we come to the science of man. In the rational creatures—man and the gods—Pneuma is manifested in a high degree of purity and intensity as an emanation from the world-soul, itself an emanation from the primary substance of purest ether,—a spark of the celestial fire, or, more accurately, fiery breath, which is a mean between fire and air, characterized by vital warmth more than by dryness. The physical basis of Stoic psychology deserves the closest attention. On the one hand, soul is corporeal, else it would have no real existence, would be incapable of extension in three dimensions (and therefore of equable diffusion all over the body), incapable of holding the body together, as the Stoics contended that it does, herein presenting a sharp contrast to the Epicurean tenet that it is the body which confines and shelters the light vagrant atoms of soul. On the other hand, this corporeal thing is veritably and identically reason, mind, and ruling principle (λόγος, νοῦς, ἡγεμονικόν), in virtue of its divine origin. Cleanthes can say to Zeus, "We too are thy offspring," and a Seneca can calmly insist that, if man and God are not on perfect equality, the superiority rests rather on our side. What God is for the world that the soul is for man. The Cosmos must be conceived as a single whole, its variety being referred to varying stages of condensation in Pneuma. So, too, the human soul must possess absolute simplicity, its varying functions being conditioned by the degrees or species of its tension. It follows that of "parts" of the soul, as previous thinkers imagined, there can be no question; all that can consistently be maintained is that from the centre of the body—the heart—seven distinct air-currents are discharged to various organs, which are so many modes of the one soul's activity.[1] The ethical consequences of this position will be seen at a later stage.

Theory of knowledge.

With this psychology is intimately connected the Stoic theory of knowledge. From the unity of soul it follows that all psychical processes,—sensation, assent, impulse,—proceed from reason, the ruling part; that is to say, there is no strife or division: the one rational soul alone has sensations, assents to judgments, is impelled towards objects of desire just as much as it thinks or reasons. Not that all these powers at once reach full maturity. The soul at first is void of content; in the embryo it has not developed beyond the nutritive principle of a plant (φύσις); at birth the "ruling part" is a blank tablet, although ready prepared to receive writing. This excludes all possibility of innate ideas or any faculty akin to intuitive reason. The source of all our knowledge is experience and discursive thought, which manipulates the materials of sense. Our ideas are copied from stored-up sensations. No other theory was possible upon the foundation of the Stoic physics.

Note the parallel between the macrocosm and the microcosm. The soul of the world fills and penetrates it: in like manner, the human soul pervades and breathes through all the body, informing and guiding it, stamping the man with his essential character of rational. There is in both alike a ruling part, though this is situate in the human heart at the centre,—not in the brain, as the analogy of the celestial ether would suggest. Finally, the same cause, a relaxation of tension, accounts for sleep, decay, and death of man and for the dissolution of the world; after death the disembodied soul can only maintain its separate existence, even for a limited time, by mounting to that region of the universe which is akin to its nature. It was a moot point whether all souls so survive, as Cleanthes thought, or the souls of the wise and good alone, which was the opinion of Chrysippus; in any case, sooner or later individual souls are merged in the soul of the universe, from which they proceeded. The relation of the soul of the universe to God is quite clear: it is an inherent property, a mode of His activity, an effluence or emanation from the fiery ether which surrounds the universe, penetrating and permeating it. A Stoic might consistently maintain that World Soul, Providence, Destiny, and Germinal Reason are not mere synonyms, for they express different aspects of God, different relations of God to things. We find ourselves on the verge of a system of abstractions, or "attributes turned into entities," as barren as any excogitated in mediæval times. In a certain sense, Scholasticism began with Chrysippus. To postulate different substances as underlying the different forces of nature would have been to surrender the fundamental thought of the system. What really *is*—the Pneuma—neither increases nor diminishes; but its modes of working, its different currents, can be conveniently distinguished and enumerated as evidence of so many distinct attributes.

Perception.

One inevitable consequence of materialism is that subject and object can no longer be regarded as one in the act of perception, as Plato and Aristotle tended to assume, however imperfectly the assumption was carried out. The presumption of some merely external connexion, as between any other two corporeal things, is alone admissible, and some form of the representative hypothesis is most easily called in to account for perception. The Stoics explained it as a transmission of the perceived quality of the object, by means of the sense organ, into the percipient's mind, the quality transmitted appearing as a disturbance or impression upon the corporeal surface of that "thinking thing," the soul. Sight is taken as the typical sense. A conical pencil of rays diverges from the pupil of the eye, so that its base covers the object seen. In sensation a presentation is conveyed by an air current, from the sense organ, here the eye, to the mind, *i.e.*, the soul's "ruling part" in the breast; the presentation, besides attesting its own existence, gives further information of its object,—visible colour or size, or whatever be the quality in the thing seen. That Zeno and Cleanthes crudely compared this presentation to the impression which a seal bears upon wax, with protuberances and indentations, while Chrysippus more prudently determined it vaguely as an occult modification or "mode" of mind, is an interesting but not intrinsically important detail. But the mind is no mere passive recipient of impressions from without; in the view of the Stoics. Their analysis of sensation supposes it to react, by a variation in tension, against the current from the sense-organ; and this is the mind's assent or dissent, which is inseparable from the sense presentation. The contents of experience are not all alike true or valid: hallucination is possible; here the Stoics join issue with Epicurus. It is necessary, therefore, that assent should not be given indiscriminately; we must determine a criterion of truth, a special formal test whereby reason may recognize the merely plausible and hold fast the true. In an earlier age such an inquiry would have seemed superfluous. To Plato and Aristotle the nature and operation of thought and reason constitute a sufficient criterion. Since their day not only had the opposition between sense and reason broken down, but the reasoned scepticism of Pyrrho and Arcesilaus had made the impossibility of attaining truth the primary condition of wellbeing. Yet the standard which ultimately found acceptance in the Stoic school was not put forward, in that form, by its founder. Zeno, we have reason to believe, adopted the Cynic Logos for his guidance to truth as well as to morality. As a disciple of the Cynics he must have started with a theory of knowledge somewhat like that developed in the third part of Plato's *Theætetus* (201 C *sq.*),—that simple ideas are given by sense, whereas "opinion," which is a complex of simple ideas, only becomes knowledge when joined with Logos. We may

[1] These derivative powers include the five senses, speech, and the reproductive faculty, and they bear to the soul the relation of qualities to a substance. The ingenious essay of Mr R. D. Archer Hind on the Platonic psychology (*Jour. of Phil.*, vol. x. p. 120) aims at establishing a parallel unification on the spiritualistic side; comp. *Rep.*, x. 612 A.

further suppose that the more obvious of Plato's objections had led to the correction of "reason" into "right reason" However that may be, it is certain from Aristotle (*Nic Eth*, vi 13, 1144b, 17) that virtue was defined as a "habit" in accordance with right reason, and (Diog Laer, vii 54) from that the earlier Stoics made right reason the standard of truth The law which regulates our action is thus the ultimate criterion of what we know,—practical knowledge being understood to be of paramount importance But this criterion was open to the persistent attacks of Epicureans and Academics, who made clear (1) that reason is dependent upon, it not derived from sense, and (2) that the utterances of reason lack consistency Chrysippus, therefore, conceded something to his opponents when he substituted for the Logos the new standards of sensation (αἴσθησις) and general conception (πρόληψις=anticipation, *i e*, the generic type formed in the mind unconsciously and spontaneously) At the same time he was more clearly defining and safeguarding his predecessors' position For reason is consistent in the general conceptions wherein all men agree, because in all alike they are of spontaneous growth Nor was the term sensation sufficiently definite The same Chrysippus fixed upon a certain characteristic of true presentations, which he denoted by the much disputed term "apprehensive" (καταληπτικὴ φαντασία) Provided the sense organ and the mind be healthy, provided an external object be really seen or heard, the presentation, in virtue of its clearness and distinctness, has the power to extort the assent which it always lies in our power to give or to withhold

Criterion of truth

Formerly this technical phrase was explained to mean "the perception which irresistibly compels the subject to assent to it as true" But this, though apparently supported by Sextus Empiricus (*Adv Math*, vii 257), is quite erroneous, for the presentation is called καταληπτόν, as well as καταληπτικὴ φαντασία, so that beyond all doubt it is something which the percipient subject grasps, and not that which grasps or "lays hold of" the percipient Nor, again, is it wholly satisfactory to explain καταληπτική as virtually passive, "apprehensible," like its opposite ἀκατάληπτος, for we find ἀντιληπτικὴ τῶν ὑποκειμένων used as an alternative phrase (*ib*, vii 218) It would seem that the perception intended to constitute the standard of truth is one which, by producing a mental counterpart of a really existent external thing, enables the percipient, in the very act of sense, to "lay hold of" or apprehend an object in virtue of the presentation or sense impression of it excited in his own mind The reality of the external object is a necessary condition, to exclude hallucinations of the senses, the exact correspondence between the external object and the internal precept is also necessary, but naturally hard to secure, for how can we compare the two? The external object is known only in perception However, the younger Stoics endeavoured to meet the assaults of their persistent critic Carneades by suggesting various modes of testing a single presentation, to see whether it were consistent with others, especially such as occurred in groups, &c, indeed, some went so far as to add to the definition "coming from a real object and exactly corresponding with it" the clause "provided it encounter no obstacle"

Degrees of knowledge

The same criterion was available for knowledge derived more directly from the intellect Like all materialists, the Stoics can only distinguish the sensible from the intelligible as thinking when the external object is present (αἰσθάνεσθαι) and thinking when it is absent (ἐννοεῖν) The product of the latter kind includes memory (though this is upon a strict analysis, something intermediate) and conceptions or general notions, under which were confusedly classed the products of the imaginative faculty The work of the mind is seen first in "assent", if to a true presentation the result is "simple apprehension" (κατάληψις this stands in close relation to the καταληπτικὴ φαντασία, of which it is the necessary complement), if to a false or unapprehensive presentation, the result is "opinion" (δόξα), always deprecated as akin to error and ignorance, unworthy of a wise man These processes are conceivable only as "modes" of mind, changes in the soul's substance, and the same is true of the higher conceptions, the products of generalization But the Stoics were not slow to exalt the part of reason, which seizes upon the generic qualities, the essential nature of things Where sense and reason conflict, it is the latter that must decide One isolated "apprehension," however firm its grasp, does not constitute knowledge or science (ἐπιστήμη), it must be of the firmest, such as reason cannot shake, and, further, it must be worked into a system of such apprehensions, which can only be by the mind's exercising the "habit" (ἕξις) of attaining truth by continuous tension Here the work of reason is assimilated to the force which binds together the parts of an inorganic body and resists their separation There is nothing more in the order of the universe than extended mobile bodies and forces in tension in these bodies So, too, in the order of knowledge there is nothing but sense and the force of reason maintaining its tension and connecting sensations and ideas in their proper sequence Zeno compared sensation to the outstretched hand, flat and open, bending the fingers was assent, the clenched fist was "simple apprehension," the mental grasp of an object, knowledge was the clenched fist tightly held in the other hand The illustration is valuable for the light it throws on the essential unity of diverse intellectual operations, as well as for enforcing once more the Stoic doctrine that different grades of knowledge are different grades of tension Good and evil, virtues and vices, remarks Plutarch, are all capable of being "perceived", sense, this common basis of all mental activity, is a sort of touch by which the ethereal Pneuma which is the soul's substance recognizes and measures tension

Logic.

With this exposition we have already invaded the province of logic To this the Stoics assigned a miscellany of studies—rhetoric, dialectic, including grammar, in addition to formal logic, —to all of which their industry made contributions Some of their innovations in grammatical terminology have lasted until now we still speak of oblique cases, genitive, dative, accusative, of verbs active (ὀρθά), passive (ὕπτια), neuter (οὐδέτερα), by the names they gave Their corrections and fancied improvements of the Aristotelian logic are mostly useless and pedantic Judgment (ἀξίωμα) they defined as a complete idea capable of expression in language (λεκτὸν αὐτοτελές), and to distinguish it from other enunciations, as a wish or a command, they added "which is either true or false" From simple judgments they proceeded to compound judgments, and declared the hypothetical syllogism to be the normal type of reason, of which the categorical syllogism is an abbreviation Perhaps it is worth while to quote their treatment of the categories Aristotle made ten, all co-ordinate, to serve as 'heads of predication' under which to collect distinct scraps of information respecting a subject, probably a man For this the Stoics substituted four *summa genera*, all subordinate, so that each in turn is more precisely determined by the next They are Something, or Being, determined as (1) substance or subject matter, (2) essential quality, *i e*, substance qualified, (3) mode or chance attribute, *i e*, qualified substance in a certain condition (πως ἔχον), and, lastly, (4) relation or relative mode (in full ὑποκείμενον ποιὸν πρός τί πως ἔχον) The zeal with which the school prosecuted logical inquiries had one practical result—they could use to perfection the unrivalled weapon of analysis Its chief employment was to lay things bare and sever them from their surroundings, in order that they might be contemplated in their simplicity, with rigid exactness, as objects of thought, apart from the illusion and exaggeration that attends them when presented to sense and imagination The very perfection and precision of this method constantly tempted the later Stoics to abuse it for the systematic depreciation of the objects analysed

Ethics

The practical philosophy of the Stoics stands in the closest connexion with their physics and psychology Holding that man is a being who acts as well as thinks, and that this is the all-important side of his life, they find the link between the two in the mind's assent, for, when impelled towards certain objects by a prompting or "impulse" (ὁρμή=movement of the soul seeking to possess itself of certain external things), whether of nature or reason, a man must needs judge the objects to be desirable, the subsequent movement, as it were, translates this judgment into action Against the sceptical position it was necessary to maintain—(1) that motion, and therefore moral action, cannot follow upon the mere presentment of an idea, unless the idea so suggested receive assent, and (2) that assent alone does not suffice without the motive faculty which is found in all animals [1] Of our various impulses, some in the mature man are (α) rational, some, as in the child, are (β) non-rational, because anterior to reason, while (γ) the impulse of the man may be contrary to reason, under the influence of the affections or passions (α) Now reason, as a spring of action, has for its aim harmony or self-consistency, a life proceeding upon a single plan (τὸ ὁμολογουμένως ζῆν, τοῦτο δ' ἐστὶ καθ' ἕνα λόγον καὶ συμφώνως ζῆν) in this there is a certain symmetry or beauty, the attraction which excites rational impulse towards it Clearly this definition of the end of action comes from the Cynics, who pithily expressed it by saying that in order to live man needs either reason or a halter (δεῖν λόγον ἢ βρόχον) But during Zeno's early studies another conception had been current, that of agreement with nature Apparently it had been started by the Old Academy, where probably the technical phrase "first

Rational impulse

[1] πάσας δὲ τὰς ὁρμὰς συγκαταθέσεις εἶναι, τὰς δὲ πρακτικὰς καὶ τὸ κινητικὸν περιέχειν,—Stobæus, *Ecl Eth*, ii 164

objects according to nature," τὰ πρῶτα κατὰ φύσιν, had its origin. Now the slightest acquaintance with Stoic physics shows that reason and nature are at one; we may therefore well believe that Zeno himself had explained his harmonious or self-consistent life to mean a life in harmony with nature (Diog. Laer., vii. 87, quoting Zeno, "On the Nature of Man"). At all events that was the orthodox formula adopted and interpreted by Cleanthes and Chrysippus,—the former, as we might have expected from his Heraclitean tendencies, representing it to mean "harmony with the universal nature," the latter emphasizing that not only is it the nature of the universe, but the particular nature of man, that is meant. Cleanthes's interpretation is at once novel and fruitful: reason being the true self or nature of man, and being essentially the same in him with the reason in the All, its procedure in him should correspond to and reproduce its procedure in the All. It is reasonable, therefore, for the individual to submit to and co-operate with the indwelling reason, or law of the universe, and in obedience to this universal law (κοινὸς νόμος) imitate the uniform methodic march of the divine creative fire. Here we note the conception of morality as obedience to an objective law, though, as reason attains to consciousness of itself only in man, it is a law of which he himself, *qua* rational, is lawgiver. But Chrysippus, in his reading of the formula, had no intention of relaxing the close dependence of ethics upon physics. A new light is thrown upon the study of external nature by the essential unity of reason in the macrocosm and in the microcosm: what we learn of its operations there is profitable for instruction here, and life should be directed in accordance with the experience we have acquired of the course of nature (ζῆν κατ' ἐμπειρίαν τῶν φύσει συμβαινόντων, Chrysippus ap. Stob., *Ecl.*, ii. 134). Whether man will comply with the commands of the universal law or not, whether therefore the ethical end is realized in him, must depend upon himself. The whole tendency of the physical theory is towards a system of rigid determinism, nay, almost of fatalism; but, so soon as we reach the ethical region, the problem of indeterminism is forced upon us in all its perplexity.

Instinct. (β) Having determined the end of rational action, we must now give a glance at the earlier, instinctive activity of beings properly without reason (*i.e.*, of children and the brute creation); this too has its importance, since before reason is developed the agent follows the "uncorrupted impulses" of nature. Here we come upon a controversy which still has an interest for the psychologist, for Epicurus had declared pleasure to be the end of all instinctive activity, while the Stoics combated his position and sought to prove that not pleasure but self-preservation is really sought. According to them, the child or the animal would speedily be crushed out of existence if it did not move at all or if its movements were not governed by some plan; a vague consciousness of itself and a love for its own constitution must be postulated to account for the impulse which, together with sensation, distinguishes animal life from the life of the plant.[1] That all motion is excited by pleasure in prospect, or the hope of cessation from pain, is (they argue) contrary to fact. Efforts to move are made perseveringly even where they occasion pain. The whole life of unreasoning infancy and of the brutes can be satisfactorily explained on the assumption of sense and impulse acting mechanically, somewhat after the fashion indicated rather than worked out in detail in the Peripatetic application of the practical syllogism to the motion of animals. In their theory of pleasure itself the Stoics approximate very decidedly to Aristotle. It is, as he said, a concomitant (ἐπιγέννημα), but not of all activities; on the contrary, the highest are without it, and it is invariably of no significance where it is found. Moreover, while Aristotle had asserted that it adds a certain zest or finish to natural activity, the Stoics declared that it never appears at all except as a mark of the decline or relaxation of vital energy, the bloom which is indeed a mark of ripeness but also the certain precursor of decay. Pleasure.

(γ) To return to impulse,—there remains the case of action against reason under the influence of the passions. Although nature may guide man towards the right objects, she does not control the impetus or velocity of the soul's movement. If this be in excess, the rational soul is hurried into an inflamed disorderly condition, the source of which is an erroneous judgment or false opinion, though its effects are seen in the evident elation or depression, and the stings of excitement, which are the symptoms of mental disorder. Anxious to uphold individual responsibility, the Stoics pronounced the false opinion to be voluntary; that once granted, the subsequent reaction of the mind (*i.e.*, the emotional effects on which Zeno especially dwelt), the compulsion and extravagance which are characteristic of the passions, may be said to follow inevitably, so that under the sway of blind impulses the man is still acting voluntarily. This sets in a striking light the close dependence of ethics upon psychology. The Peripatetics had made the intellectual soul with virtues of its own something altogether distinct from the lower nature, the seat of the emotions and of the moral virtues which consist in their regulation. The Stoic doctrine of the essential unity of soul is a vehement protest against all this: the soul's unity is shown in a unity of activity, whether it be in a healthy or a disordered state. As all virtues are essentially one, though they differ according to the different relations to which the knowledge of good and evil is applied, so, too, emotion is not something antagonistic to reason, but perverted reason. There is no such struggle of vicious inclinations against virtue, a contest waged by two separate powers, as Aristotle had imagined in his account of moral weakness; the proper simile is a mutiny or revolt in one and the same city, Mansoul now in allegiance to the rightful authority and now in open rebellion. The lower animals and children are incapable of emotion; it is only found where reason is fully developed. The analysis and classification of these affections start with the false opinion or judgment or imagination, which may relate to the present or the future, to fancied good or fancied ill. Hence there are four types of the affections: all are grouped around pleasure, an impulse towards present fancied good; desire, an impulse towards future fancied good; grief, an impulse to shun fancied evil in the present; fear, an impulse to shun fancied evil in the future. On the analogy of bodily disease, these disorders of the mind are further divided into (1) chronic ailments (νοσήματα), such as avarice, where the belief that money is a good is persistent and deep-seated, leading to a habit of feeling and acting, or ambition, a similar erroneous judgment in respect of public honours, and (2) infirmities (ἀρρωστήματα), sudden attacks of error to which the patient momentarily succumbs. This remarkable development of Stoic principles leads to the demand for the entire suppression of the affections (ἀπάθεια), in contradistinction to that regulation and governance of them for which Plato and The affections.

[1] πρῶτον οἰκεῖον εἶναι παντὶ ζῴῳ τὴν αὑτοῦ σύστασιν καὶ τὴν ταύτης συνείδησιν. The σύστασις of an organic being is an outcome of internal forces, a mutual relation of varying elements,—in man, a relation of the ruling part of the soul, *i.e.*, the rational soul, to the rest. By οἰκείωσις is meant that nature inspires this self love, "for it is improbable that nature should estrange the living thing from itself, or that she should leave the creature she had made without either estrangement from, or affection for, its own constitution."

the Old Academy contended (μετριοπάθεια) Further, it explains the incessant war which the later Stoics waged with imagination

Right reason

The end of action has then been explained to be a consistent life, a rational life, and, lastly, a life according to nature Now the Cynics had already traced back consistency to a certain Herculean strength or force of will, which again is an effect of the bracing or tension of the soul's substance, so that this ever-recurring attribute is as available to explain will as intelligence Herein we discover, as it were, an internal source of the external harmony and regularity of a consistent life Our will should be directed to this source rather than to its manifestations,—to "right" (*i e*, inflexible and straight) "reason," which has attained a character of intense rigidity, an intensive energy raised to an impassable degree For this infallible firmness of the reason the technical term is διάθεσις, a "disposition" which, like straightness or crookedness in a line, admits of no degrees of less or more, thence comes harmony, regularity, and consistency in all our acts, which alone is truly beautiful (καλόν = fair or noble, for which the Romans characteristically said *honestum* = honourable) Not even Christianity laid more stress upon inwardness, or taught more explicitly that motive counts for everything and external performance for very little Once let the reason become "right" and it imparts this same character to all that it affects First the soul is made strong, healthy, beautiful, when, therefore, it thus fulfils all the conditions of its being, it is absolutely perfect

Virtue

Now the perfection of anything is called its virtue, the virtue of man, then, is the perfection of his soul, *i e*, of the ruling part or rational soul But "out of the heart are the issues of life" make the soul perfect and you make the life perfect From such a "disposition" must proceed a life which flows on smoothly and uniformly, like a gentle river (εὔροια βίου) No longer is there anything to hope or fear, this harmonious accord between impulses and acts is itself man's wellbeing or welfare (εὐδαιμονία) Cleanthes scouts the notion of adding to such perfection that occasional result of a decaying activity entitled pleasure, Chrysippus remonstrates indignantly with Plato for appealing to the "moral bugbears" of future rewards or punishments There is no "wages of virtue," not even the continuance of her activity, for lapse of time can add nothing to perfect wellbeing, it is complete, whole, and indivisible now

Virtue, then, as right reason, is at once knowledge and strength of will, for a right comprehension of Stoic psychology shows that these two are identical The unity of all virtue is sufficiently apparent, but the Stoics also acknowledged a plurality of specific virtues grouped round the four cardinal virtues of Plato Wisdom (φρόνησις) was, according to Zeno and Cleanthes, the common element, according to Aristo, it should rather be termed knowledge (ἐπιστήμη), and this view was adopted in the school to avoid the awkwardness of using the same term (φρόνησις) both for a special virtue and for the generic attribute of them all Wisdom or knowledge in distributing to others is justice, in endeavour it is temperance, in endurance it is courage or fortitude, but in every virtuous act all four of the virtues are implicit Virtue is thus the unconditional good, it is at once the absolute end and the means to the end

Goodness must be interpreted, as Socrates used to interpret it, that which furnishes some advantage or true utility, its opposite, evil, as that which produces harm or disadvantage Obviously only virtue, and that which comes from virtue, confers any real advantage, only vice can really do harm Goodness is a wider genus than virtue, all virtue is good, but not all goods are virtues There are goods of soul, such as habits and happy aptitudes which may be acquired in varying degrees (*i e*, they are ἕξεις not διαθέσεις), others are only single actions (ἐνέργειαι) A friend again may be a means to good (ποιητικὸν τέλους) All these goods are utilities (ὠφελήματα), and therefore deserve to be sought (αἱρετά) Similarly evils may be classified as—(1) vices, settled dispositions contrary to right reason, proceeding from that ignorance which infallibly attends on a slackening of the soul's fibre, (2) evil habits or inclinations (εὐκαταφορίαι), (3) isolated vicious actions All these evils alike are to be shunned (φευκτά), all alike are harmful (βλάμματα), the moral responsibility rests with the individual, in so far as he is ignorant or has his soul relaxed

Things indifferent.

Good and evil, however, is not an exhaustive classification There is a large class of things which are neither the one nor the other, which do not conduce to our attainment of the end, nor hinder us therefrom, which are neither to be pursued nor shunned, but are simply indifferent (ἀδιάφορα) To all these objects the attitude of the Cynics was complete indifference, wherein they were followed by Aristo, that of the sceptics professedly utter insensibility Now the most original feature of the Stoic ethics is the classification of things indifferent and their arrangement in a certain scale in accordance with the value, positive or negative (ἀξία, ἀπαξία), to be assigned to them either intrinsically or in certain circumstances (κατὰ περίστασιν) Some objects are so unimportant that in regard to them Aristo's attitude of complete indifference is justified Placing them at the zero point, we may advance in both directions, assigning to all the objects of instinctive natural impulses a positive value, in virtue of which they are to be picked out (ληπτά) in preference to other indifferent things not of this description Thus bodily health, though not a good, is entitled to a certain value, disease, though not an evil, has a certain negative value The former class is according to nature, the latter contrary to nature, the former are instinctively sought by children as tending to maintain their "constitution" or nature, the latter their "uncorrupted impulses" (ἀδιάστροφοι ἀφορμαί) lead them to shun as tending to mar, cripple, or destroy life Similarly, actions may be classified all virtuous actions are right actions (κατορθώματα), all vicious actions are wrong actions or "sins" (ἁμαρτήματα) The attainment of any one of the objects in the class of things indifferent, looked at in itself, is neither right nor wrong But, if the object picked out be that object out of all at the moment present to us which has the highest value, then the action of selecting it admits of being defended on probable grounds, and as such is entitled to be called (quite apart from the agent's disposition, whether virtuous or vicious), *materialiter*, an act "meet and fit" to do (καθῆκον) Such an act need not be preceded by any reasoning at all, in the case of the brutes and of children it is always instinctive, yet in all cases it is capable of being justified on grounds of probability (ὃ πραχθὲν εὔλογον ἔχει ἀπολογίαν). Similarly with the selection of an object which has less value in preference to one of higher value such a blunder is not, taken in itself, a wrong action, but it violates fitness (παρὰ τὸ καθῆκον) Amongst fitting actions, some are always fitting, others only at times, under given circumstances, some indifferent objects we select for their own sakes, others merely as means The range of such human functions is wide enough to include the acquisition of information, the exercise of temperance and courage, even altruistic conduct And yet some actions in man are on a level with the nutritive functions of the plant (Diog Laer, vii 86) Again, our human functions compose our whole conscious life, even life, then, considered in itself, has in it no moral good, we may, if need be, under certain circumstances, voluntarily withdraw from it

Fitness, or external duty

The Stoics maintain that the variety of things indifferent is essential to virtue, because it is the field upon which reason is exercised Virtue is a body, therefore it is corporeal, therefore its active principle needs a passive material to act upon Things indifferent are capable of being put to a good or a bad use, though some lend themselves to use more easily than others Nor does virtue merely avail itself, now and then, of things indifferent,—it can do nothing else than avail itself of them Though they are not goods, and though their attainment does not confer wellbeing, yet all virtue is the selection or choice of them. For how is a

virtuous life manifested? In a series of external acts, each one of which is the choice of some natural end, some object according to nature, as possessing at the moment the highest value. The same external act may be done by an irrational agent, and in his case the act is not virtuous. For there is as great a gulf fixed between fitting and virtuous actions as between things indifferent having positive value and the good. No increase of value can raise a thing indifferent to the class of good, no degree of fitness in the external act done can render it virtuous. As right actions consist in following reason in the selection of things according to nature, it follows that such right actions (as distinct from the fitting actions of which all living things are capable) are the exclusive privilege of rational beings. So, too, with wrong actions: only rational beings can perform them, although children or the brutes may run counter to fitness, and pursue objects contrary to nature, they cannot be said to sin or do wrong. All actions, then, of rational beings must be either virtuous or vicious, there is no mean between the two. But what of fitting actions? Are not they also done by rational agents? Is not the distinction between right conduct and mere external fitness continually drawn when the Stoics are referring to the activity of rational human beings? Unquestionably so, but in examining a given act it is necessary to view it on the formal as well as on the material side,—as proceeding from a virtuous or vicious disposition, and again as tending, when taken in itself and apart from this disposition, to promote or destroy the agent's nature or constitution, *i e*, as something "meet and fit" to do, or as contrary to fitness (or, in rare cases, as having no tendency in either direction). Lastly, the analysis of conduct is incomplete unless the external object which the agent aims at attaining by the act is also taken into account: it may be natural, and may therefore excite desire, or it may be contrary to nature, and excite aversion, or it may be absolutely indifferent. Now the Stoic classifications of (*a*) external objects and (*b*) actions (as they have come down to us from not very discriminating sources) are hampered by the inclusion of right actions and wrong actions, which are made species of the wider genera. Under objects according to nature come (*α*) fitting actions, (*β*) right actions, (*γ*) virtues, *i e*, conduct which is perfect contains all that in the imperfect imitates perfection: a right action has *ipso facto* all the fitness of a fitting action, and all the accord with nature of a thing according to nature. So with the opposite class: the vicious man, by the very fact of not having the tension of soul which is virtue, commits a sin in his every action, all that he does, therefore, is on this ground contrary to fitness and contrary to nature. Any defect in external conduct proves it to be a sin, the mere absence of defect does not establish its claim to be right conduct. It is as easy to prove a given person is unwise (and therefore a sinner) as it is hard to prove him a sage. Virtue is one, vice is manifold.

No act in itself is either noble or base, even the grossest violation of fitness, if it could be done with the right intention, would count as virtue, and the most fitting deeds without that intention are naught (see Orig, *C Cels*, iv 45, Sext Emp, *Adv Math*, xi 190, *Pyrrh Hyp*, iii 245, is therefore wrong). It does not appear, then, that there is any divergence in principle between the doctrine of the end of action and the doctrine of fitness or relative duty, nor should the latter be regarded (as is done by Cicero and some modern expositors) as an afterthought, intended to soften the too rigorous demands of the Stoic ideal. For from the first it was an integral part of the system. Zeno wrote a treatise περὶ τοῦ καθήκοντος, indeed he adopted it as a technical term. That this doctrine was a stumbling-block to the small band of his early disciples seems not unlikely, for Aristo and Herillus, who left him, as is believed, on independent grounds, modified it in their own ethical theories afterwards put forth. According to Hirzel (*Untersuch*, ii p 54), however, the views of these two heterodox Stoics more closely approximated than at first sight appears. Herillus, as well as Aristo, maintained that all actions intermediate to vice and virtue are absolutely indifferent (Diog Laer, vii 155), and Aristo, like Herillus, defined virtue as knowledge, and held that the wise man will never form opinions, *i e*, will not act upon anything short of knowledge.

Cosmopolitanism

In their view of man's social relations the Stoics are greatly in advance of preceding schools. We saw that virtue is a law which governs the universe: that which Reason and God ordain must be accepted as binding upon the particle of reason which is in each one of us. Human law comes into existence when men recognize this obligation, justice is therefore natural, and not something merely conventional. The opposite tendencies, to allow to the individual responsibility and freedom, and to demand of him obedience to law, are both features of the system, but in virtue even of the freedom which belongs to him *qua* rational, he must recognize the society of rational beings of which he is a member, and subordinate his own ends to the ends and needs of this society. Those who own one law are citizens of one state, the city of Zeus, in which men and gods have their dwelling. In that city all is ordained by reason working intelligently, and the members exist for the sake of one another, there is an intimate connexion (συμπάθεια) between them which makes all the wise and virtuous friends, even if personally unknown, and leads them to contribute to one another's good. Their intercourse should find expression in justice, in friendship, in family and political life. But practically the Stoic philosopher always had some good excuse for withdrawing from the narrow political life of the city in which he found himself. The circumstances of the time, such as the decay of Greek city-life, the foundation of large territorial states under absolute Greek rulers which followed upon Alexander's conquests, and afterwards the rise of the world-empire of Rome, aided to develop the leading idea of Zeno's *Republic*. There he had anticipated a state without family life, without law courts or coins, without schools or temples, in which all differences of nationality would be merged in the common brotherhood of man. This cosmopolitan citizenship remained all through a distinctive Stoic dogma, when first announced it must have had a powerful influence upon the minds of men, diverting them from the distractions of almost parochial politics to a boundless vista. There was, then, no longer any difference between Greek and barbarian, between male and female, bond and free. All are members of one body as partaking in reason, all are equally men. Not that this led to any movement for the abolition of slavery. For the Stoics attached but slight importance to external circumstances, since only the wise man is really free, and all the unwise are slaves. Yet, while they accepted slavery as a permanent institution, philosophers as wide apart as Chrysippus and Seneca sought to mitigate its evils in practice, and urged upon masters humanity in the treatment of their slaves.

Religion

The religious problem had peculiar interest for the school which discerned God everywhere as the ruler and upholder, and at the same time the law, of the world that He had evolved from Himself. The physical groundwork lends a religious sanction to all moral duties, and Cleanthes's noble hymn is evidence how far a system of natural religion could go in providing satisfaction for the cravings of the religious temper:—

"Most glorious of immortals, O Zeus of many names, almighty and everlasting, sovereign of nature, directing all in accordance with law, thee it is fitting that all mortals should address. Thee all this universe, as it rolls circling round the earth, obeys wheresoever thou dost guide, and gladly owns thy sway. Such a minister thou holdest in thy invincible hands,—the two edged, fiery, ever-living thunderbolt, under whose stroke all nature shudders. No work upon earth is wrought apart from thee, lord, nor through the divine ethereal sphere, nor upon the sea, save only whatsoever deeds wicked men do in their own foolishness. Nay, thou knowest how to make even the rough smooth, and to bring order out of disorder, and things not friendly are friendly in thy sight. For so hast thou fitted all things together, the good with the evil, that there might be one eternal law over all. Deliver men from fell ignorance. Banish it, father, from their soul, and grant them to obtain wisdom, whereon relying thou rulest all things with justice."

To the orthodox theology of Greece and Rome the system stood in a twofold relation, as criticism and rationalism. That the popular religion contained gross errors hardly needed to be pointed out. The forms of worship were known to be trivial or mischievous, the myths unworthy or immoral. But Zeno declared images, shrines, temples, sacrifices, prayers, and worship to be of no avail. A really acceptable prayer, he taught, can only have reference to a virtuous and devout mind. God is best worshipped in the shrine of the heart by the desire to know

and obey Him At the same time the Stoics felt at liberty to defend and uphold the truth in polytheism Not only is the primitive substance God, the one supreme being, but divinity must be ascribed to His manifestations,—to the heavenly bodies, which are conceived, like Plato's created gods, as the highest of rational beings, to the forces of nature, even to deified men, and thus the world was peopled with divine agencies Moreover, the myths were rationalized and allegorized, which was not in either case an original procedure The search for a deeper hidden meaning beside the literal one had been begun by Democritus, Empedocles, the Sophists, and the Cynics It remained for Zeno to carry this to a much greater extent, and to seek out or invent "natural principles" (λόγοι φυσικοί) and moral ideas in all the legends and in the poetry of Homer and Hesiod In this sense he was the pattern if not the "father" of all such as allegorize and reconcile Etymology was pressed into the service, and the wildest conjectures as to the meaning of names did duty as a basis for mythological explanations The two favourite Stoic heroes were Hercules and Ulysses, and nearly every scene in their adventures was made to disclose some moral significance Lastly, the practice of divination and the consultation of oracles afforded a means of communication between God and man,—a concession to popular beliefs which may be explained when we reflect that to the faithful divination was something as essential as confession and spiritual direction to a devout Catholic now, or the study and interpretation of Scripture texts to a Protestant Chrysippus did his best to reconcile the superstition with his own rational doctrine of strict causation Omens and portents, he explained, are the natural symptoms of certain occurrences There must be countless indications of the course of Providence, for the most part unobserved, the meaning of only a few having become known to men His opponents argued, "if all events are foreordained, divination is superfluous", he replied that both divination and our behaviour under the warnings which it affords are included in the chain of causation Even here, however, the bent of the system is apparent They were at pains to insist upon purity of heart and life as an indispensable condition for success in prophesying and to enlist piety in the service of morality

Divination

Middle Stoa

When Chrysippus died (Ol 143 = 208-204 B C) the structure of Stoic doctrine was complete With the Middle Stoa we enter upon a period at first of comparative inaction, afterwards of internal reform Chrysippus's immediate successors were Zeno of Tarsus, Diogenes of Seleucia (often called the Babylonian), and Antipater of Tarsus, men of no originality, though not without ability, the two last-named, however, had all their energies taxed to sustain the conflict with CARNEADES (*q v*) This was the most formidable assault the school ever encountered, that it survived was due more to the foresight and elaborate precautions of Chrysippus than to any efforts of that "pen-doughty" pamphleteer, Antipater (καλαμοβόας), who shrank from opposing himself in person to the eloquence of Carneades The subsequent history testified to the importance of this controversy The special objects of attack were the Stoic theory of knowledge, their theology, and their ethics The physical basis of the system remained unchanged but neglected, all creative force or even original research in the departments of physics and metaphysics vanished Yet problems of interest bearing upon psychology and natural theology continued to be discussed Thus the cycles of the world's existence, and the universal conflagration which terminates each of them, excited some doubt Diogenes of Seleucia is said to have wavered in his belief at last, Boethus, one of his pupils, flatly denied it He regarded the Deity as the guide and upholder of the world, watching over it from the outside, not as the immanent soul within it, for according to him the world was as soulless as a plant We have here a compromise between Zeno's and Aristotle's doctrines But in the end the universal conflagration was handed down without question as an article of belief It is clear that the activity of these teachers was chiefly directed to ethics they elaborated fresh definitions of the chief good, designed either to make yet clearer the sense of the formulas of Chrysippus or else to meet the more urgent objections of the New Academy Carneades had emphasized one striking apparent inconsistency: it had been laid down that to choose what is natural is man's highest good, and yet the things chosen, the "first objects according to nature," had no place amongst goods Antipater may have met this by distinguishing "the attainment" of primary natural ends from the activity directed to their attainment (Plut, *De Comm Not*, 27, 14, p 1072 F), but, earlier still, Diogenes had put forward his gloss, viz, "The end is to calculate rightly in the selection and rejection of things according to nature" Archedemus, a contemporary of Diogenes, put this in plainer terms still "The end is to live in the performance of all fitting actions" (πάντα τὰ καθήκοντα ἐπιτελοῦντας ζῆν) Now it is highly improbable that the earlier Stoics would have sanctioned such interpretations of their dogmas The mere performance of relative or imperfect duties, they would have said, is something neither good nor evil, the essential constituent of human good is ignored And similar criticism is actually passed by Posidonius "This is not the end, but only its necessary concomitant, such a mode of expression may be useful for the refutation of objections put forward by the Sophists" (Carneades and the New Academy?), "but it contains nothing of morality or wellbeing" (Galen, *De Plac Hipp et Plat*, p 470 K) There is every ground, then, for concluding that we have here one concession extorted by the assaults of Carneades For a similar compromise there is express testimony "good repute" (εὐδοξία) had been regarded as a thing wholly indifferent in the school down to and including Diogenes Antipater was forced to assign to it "positive value," and to give it a place amongst "things preferred" (Cic, *De Fin*, iii 57) These modifications were retained by Antipater's successors Hence come the increased importance and fuller treatment which from this time forward fall to the lot of the "external duties" (καθήκοντα) The rigour and consistency of the older system became sensibly modified

The sage

To this result another important factor contributed In all that the older Stoics taught there breathes that enthusiasm for righteousness in which has been traced the earnestness of the Semitic spirit, but nothing presents more forcibly the pitch of their moral idealism than the doctrine of the Wise Man All mankind fall into two classes,—the wise or virtuous, the unwise or wicked,—the distinction being absolute He who possesses virtue possesses it whole and entire, he who lacks it lacks it altogether To be but a hand's-breadth below the surface of the sea ensures drowning as infallibly as to be five hundred fathoms deep Now the wise man is drawn as perfect All he does is right, all his opinions are true, he alone is free, rich, beautiful, skilled to govern, capable of giving or receiving a benefit And his happiness, since length of time cannot increase it, falls in nothing short of that of Zeus In contrast with all this, we have a picture of universal depravity Now, who could claim to have attained to the sage's wisdom? Doubtless, at the first founding of the school Zeno himself and Zeno's pupils were inspired with this hope; they emulated the Cynics Antisthenes and Diogenes, who never shrank out of

modesty from the name and its responsibilities But the development of the system led them gradually and reluctantly to renounce this hope, as they came to realize the arduous conditions involved Zeno indeed could hardly have been denied the title conferred upon Epicurus Cleanthes, the "second Hercules," held it possible for man to attain to virtue From anecdotes recorded of the tricks played upon Aristo and Sphærus (Diog Laer, vii 162, 117) it may be inferred that the former deemed himself infallible in his opinions, i e, set up for a sage, Persæus himself, who had exposed the pretensions of Aristo, is twitted with having failed to conform with the perfect generalship which was one trait of the wise man, when he allowed the citadel of Corinth to be taken by Aratus (Athen, iv 102 D) The trait of infallibility especially proved hard to establish when successive heads of the school seriously differed in their doctrine The prospect became daily more distant, and at length faded away Chrysippus declined to call himself or any of his contemporaries a sage One or two such manifestations there may have been—Socrates and Diogenes?—but the wise man was rarer, he thought, than the phœnix If his successors allowed one or two more exceptions, to Diogenes of Seleucia at any rate the sage was an unrealized ideal, as we learn from Plutarch (*De Comm Not*, 33, 1076 B), who does not fail to seize upon this extreme view Posidonius left even Socrates, Diogenes, and Antisthenes in the state of progress towards virtue

Modifications in practice

Although there was in the end a reaction from this extreme, yet it is impossible to mistake the bearing of all this upon a practical system of morals So long as dialectic subtleties and exciting polemics afforded food for the intellect, the gulf between theory and practice might be ignored But once let this system be presented to men in earnest about right living, and eager to profit by what they are taught, and an ethical reform is inevitable Conduct for us will be separated from conduct for the sage We shall be told not always to imitate him There will be a new law, dwelling specially upon the "external duties" required of all men, wise or unwise, and even the sufficiency of virtue for our happiness may be questioned The introducer and expositor of such a twofold morality was a remarkable man Born at Rhodes *c* 185 B C, a citizen of the most flourishing of Greek states and almost the only one which yet retained vigour and freedom, Panætius lived for years in the house of Scipio Africanus the younger at Rome, accompanied him on embassies and campaigns, and was perhaps the first Greek who in a private capacity had any insight into the working of the Roman state or the character of its citizens Later in life, as head of the Stoic school at Athens, he achieved a reputation second only to that of Chrysippus He is the earliest Stoic author from whom we have, even indirectly, any considerable piece of work, as books i and ii of the *De Officiis* are a *réchauffé*, in Cicero's fashion, of Panætius "Upon External Duty" (περὶ τοῦ καθήκοντος)

Stoicism in Rome

The introduction of Stoicism at Rome was the most momentous of the many changes that it saw After the first sharp collision with the jealousy of the national authorities it found a ready acceptance, and made rapid progress amongst the noblest families It has been well said that the old heroes of the republic were unconscious Stoics, fitted by their narrowness, their stern simplicity, and devotion to duty for the almost Semitic earnestness of the new doctrine In Greece its insensibility to art and the cultivation of life was a fatal defect, not so with the shrewd men of the world, desirous of qualifying as advocates or jurists It supplied them with an incentive to scientific research in archæology and grammar, it penetrated jurisprudence until the belief in the ultimate identity of the *jus gentium* with the law of nature modified the prætor's edicts for centuries Even to the prosaic religion of old Rome, with its narrow original conception and multitude of burdensome rites, it became in some sort a support Scævola, following Panætius, explained that the prudence of statesmen had established this public institution in the service of order midway between the errors of popular superstition and the barren truths of enlightened philosophy Soon the influence of the pupils reacted upon the doctrines taught Of speculative interest the ordinary Roman had as little as may be, for abstract discussion and controversy he cared nothing Indifferent to the scientific basis or logical development of doctrines, he selected from various writers and from different schools what he found most serviceable All had to be simplified and disengaged from technical subtleties

Panætius.

To attract his Roman pupils Panætius would naturally choose simple topics susceptible of rhetorical treatment or of application to individual details He was the representative, not merely of Stoicism, but of Greece and Greek literature, and would feel pride in introducing its greatest masterpieces amongst all that he studied, he valued most the writings of Plato He admired the classic style, the exquisite purity of language, the flights of imagination, but he admired above all the philosophy He marks a reaction of the genuine Hellenic spirit against the narrow austerity of the first Stoics Zeno and Chrysippus had introduced a repellent technical terminology, their writings lacked every grace of style With Panætius the Stoa became eloquent he did his best to improve upon the uncouth words in vogue, even at some slight cost of accuracy, *e g*, to discard προηγμένον for εὔχρηστον, or else designate it "so-called good," or even simply "good," if the context allowed

The part Panætius took in philological and historical studies is characteristic of the man We know much of the results of these studies, of his philosophy technically we know very little He wrote only upon ethics, where historical knowledge would be of use Crates of Mallus, one of his teachers, aimed at fulfilling the high functions of a "critic" according to his own definition,—that the critic must acquaint himself with all rational knowledge Panætius was competent to pass judgment upon the critical "divination" of an Aristarchus (who was perhaps himself also a Stoic), and took an interest in the restoration of Old Attic forms to the text of Plato Just then there had been a movement towards a wider and more liberal education, by which even contemporary Epicureans were affected Diogenes the Babylonian had written a treatise on language and one entitled *The Laws* Along with grammar, which had been a prominent branch of study under Chrysippus, philosophy, history, geography, chronology, and kindred subjects came to be recognized as fields of activity no less than philology proper It has been recently established that Polybius the historian was a Stoic, and it is clear that he was greatly influenced by the form of the system which he learned to know, in the society of Scipio and his friends, from Panætius [1] Nor is it improbable that works of the latter served Cicero as the originals of his *De Republica* and *De Legibus* [2] Thus the gulf between Stoicism and the later Cynics, who were persistently hostile to culture, could not fail to be widened

Eclecticism

A wave of eclecticism passed over all the Greek schools in the 1st century B C Platonism and scepticism had left undoubted traces upon the doctrine of such a reformer as Panætius He had doubts about a general conflagration, possibly (he thought) Aristotle was right in affirming the eternity of the present order of the world He doubted the entire system of divination On these points his disciples Posidonius and Hecato seem to have reverted to orthodoxy But in ethics his innovations were more suggestive and fertile He separated wisdom as a theoretic virtue from the other three which he called practical Hecato slightly modified this showing that precepts (θεωρήματα) are needed for justice and temperance also, he made them scientific virtues, reserving for his second class the unscientific virtue (ἀθεώρητος ἀρετή) of courage, together with

[1] Hirzel, *Untersuch*, ii p 841 *sq* Polybius's rejection of divination is decisive See, *e g*, his explanation upon natural causes of Scipio the elder's capture of New Carthage, "by the aid of Neptune," x 11 (*cf* x 2) P Voigt holds that in vi 5, 1, τισιν ἑτέροις τῶν φιλοσόφων is an allusion to Panætius

[2] This, at least, is maintained by Schmekel

health, strength, and such like "excellencies." Further, Panætius had maintained that pleasure is not altogether a thing indifferent: there is a natural as well as an unnatural pleasure. But, if so, it would follow that, since pleasure is an emotion, apathy or eradication of all emotions cannot be unconditionally required. The gloss he put upon the definition of the end was "a life in accordance with the promptings given us by nature"; the terms are all used by older Stoics, but the individual nature (ἡμῖν) seems to be emphasized.

Posidonius. From Posidonius, the last representative of a comprehensive study of nature and a subtle erudition, it is not surprising that we get the following definition: the end is to live in contemplation of the reality and order of the universe, promoting it to the best of our power, and never led astray by the irrational part of the soul. The heterodox phrase with which this definition ends points to innovations in psychology which were undoubtedly real and important, suggested by the difficulty of maintaining the essential unity of the soul. Panætius had referred two faculties (those of speech and of reproduction) to animal impulse and to the vegetative "nature" (φύσις) respectively. Yet the older Stoics held that this φύσις was changed to a true soul (ψυχή) at birth. Posidonius, unable to explain the emotions as "judgments" or the effects of judgments, postulated, like Plato, an irrational principle (including a concupiscent and a spirited element) to account for them, although he subordinated all these as faculties to the *one* substance of the soul lodged in the heart. This was a serious departure from the principles of the system, facilitating a return of later Stoicism to the dualism of God and the world, reason and the irrational part in man, which Chrysippus had striven to surmount.[1]

Yet in the general approximation and fusion of opposing views which had set in, the Stoics fared far better than rival schools. Their system became best known and most widely used by individual eclectics. All the assaults of the sceptical Academy had failed, and within fifty years of the death of Carneades his degenerate successors, unable to hold their ground on the question of the criterion, had capitulated to the enemy. Antiochus of Ascalon, the professed restorer of the Old Academy, taught a medley of Stoic and Peripatetic dogmas, which he boldly asserted Zeno had first borrowed from his school. The wide diffusion of Stoic phraseology and Stoic modes of thought may be seen on all hands,—in the language of the New Testament writers, in the compendious "histories of philosophy" industriously circulated by a host of writers about this time (*cf.* H. Diels, *Doxographi Græci*).

The later Stoics. The writings of the later Stoics have come down to us, if not entire, in great part, so that Seneca, Cornutus, Persius, Lucan, Epictetus, Marcus Aurelius are known at first hand. They do not profess to give a scientific exposition of doctrine, and may therefore be dismissed somewhat briefly (see EPICTETUS and AURELIUS). We learn much more about the Stoic system from the scanty fragments of the first founders,[2] or even from the epitomes of Diogenes Laertius and Stobæus, than from these writers. They testify to the restriction of philosophy to the practical side, and to the increasing tendency, ever since Panætius, towards a relaxation of the rigorous ethical doctrine and its approximation to the form of religious conviction. This finds most marked expression in the doctrines of submission to Providence and universal philanthropy. Only in this way could they hold their ground, however insecurely, in face of the religious reaction of the first century. In passing to Rome, Stoicism quitted the school for actual life. The fall of the republic was a gain, for it released so much intellectual activity from civic duties. The life and death of Cato fired the imagination of a degenerate age in which he stood out both as a Roman and a Stoic. To a long line of illustrious successors, men like Pætus Thrasea and Helvidius Priscus, Cato bequeathed his resolute opposition to the dominant power of the times; unsympathetic, impracticable, but fearless in demeanour, they were a standing reproach to the corruption and tyranny of their age. But when at first, under Augustus, the empire restored order, philosophy became bolder and addressed every class in society, public lectures and spiritual direction being the two forms in which it mainly showed activity. Books of direction were written by Sextius in Greek (as afterwards by Seneca in Latin), almost the only Roman who had the ambition to found a sect, though in ethics he mainly followed Stoicism. His contemporary Papirius Fabianus was the popular lecturer of that day, producing a powerful effect by his denunciations of the manners of the time. Under Tiberius, Sotion and Attalus were attended by crowds of hearers. In Seneca's time there was a professor, badly attended it is true, even in a provincial town like Naples. At the same time the antiquarian study of Stoic writings went on apace, especially those of the earliest teachers,—Zeno and Aristo and Cleanthes.

Seneca is the most prominent leader in the direction Seneca which Roman Stoicism now took. His penetrating intellect had mastered the subtleties of the system of Chrysippus, but they seldom appear in his works, at least without apology. Incidentally we meet there with the doctrines of Pneuma and of tension, of the corporeal nature of the virtues and the affections, and much more to the same effect. But his attention is claimed for physics chiefly as a means of elevating the mind, and as making known the wisdom of Providence and the moral government of the world. To reconcile the ways of God to man had been the ambition of Chrysippus, as we know from Plutarch's criticisms. He argued plausibly that natural evil was a thing indifferent,—that even moral evil was required in the divine economy as a foil to set off good. The really difficult problem why the prosperity of the wicked and the calamity of the just were permitted under the divine government he met in various ways: sometimes he alleged the forgetfulness of higher powers; sometimes he fell back upon the necessity of these contrasts and grotesque passages in the comedy of human life. Seneca gives the true Stoic answer in his treatise *On Providence*: the wise man cannot really meet with misfortune; all outward calamity is a divine instrument of training, designed to exercise his powers and teach the world the indifference of external conditions. In the soul Seneca recognizes an effluence of the divine spirit, a god in the human frame; in virtue of this he maintains the essential dignity and internal freedom of man in every human being. Yet, in striking contrast to this orthodox tenet is his vivid conception of the weakness and misery of men, the hopelessness of the struggle with evil, whether in society or in the individual. Thus he describes the body (which, after Epicurus, he calls the flesh) as a mere husk or fetter or prison of the soul, with its departure begins the soul's true life. Sometimes, too, he writes as if he accepted an irrational as well as a rational part of the soul. In ethics, if there is no novelty of doctrine, there is a surprising change in the mode of its application. The ideal sage has receded; philosophy comes as a physician, not to the whole but to the sick. We learn that there are various classes of patients in "progress" (προκοπή), *i.e.*, on their way to virtue, making painful efforts towards it. The first stage is the eradication of vicious habits: evil tendencies are to be corrected, and a guard kept on the corrupt propensities of the reason. Suppose this achieved, we have yet to struggle with single attacks of the passions: irascibility may be cured, but we may succumb to a fit of rage. To achieve this second stage the impulses must be trained in such a way that the fitness of things indifferent may be the guide of conduct. Even then it remains to give the will that property of rigid infallibility without which we are always liable to err, and this must be effected by the training of the judgment. Other

[1] Works of Posidonius and Hecato have served as the basis of extant Latin treatises: Cicero, *De Divinatione*, perhaps *De Natura Deorum*, i., ii., comes in part from Posidonius; Cicero, *De Finibus*, iii., and Seneca, *De Beneficiis*, i.-iv., from Hecato, who is also the source of Stobæus, *Ecl. Eth.*, ii. 110. *Cf.* H. H. Fowler, *Panætii et Hecatonis Fragmenta*, Bonn, 1885.

[2] *Cf.* C. Wachsmuth, *Commentationes II de Zenone Citiensi et Cleanthe Assio*, Gottingen, 1874. Baguet's *Chrysippus*, Louvain, 1822, is unfortunately very incomplete.

peculiarities of the later Stoic ethics are due to the condition of the times. In a time of moral corruption and oppressive rule, as the early empire repeatedly became to the privileged classes of Roman society, a general feeling of insecurity led the student of philosophy to seek in it a refuge against the vicissitudes of fortune which he daily beheld. The less any one man could do to interfere in the government, or even to safeguard his own life and property, the more heavily the common fate pressed upon all, levelling the ordinary distinctions of class and character. Driven inwards upon themselves, they employed their energy in severe self examination, or they cultivated resignation to the will of the universe, and towards their fellow-men forbearance and forgiveness and humility, the virtues of the philanthropic disposition. With Seneca this resignation took the form of a constant meditation upon death. Timid by nature, aware of his impending doom, and at times justly dissatisfied with himself, he tries all means of reconciling himself to the idea of suicide. The act had always been accounted allowable in the school, if circumstances should call for it; indeed, the first three teachers had found such circumstances in the infirmity of old age. But their attitude towards the "way out" (ἐξαγωγή) of incurable discomforts is quite unlike the anxious sentimentalism with which Seneca dwells upon death.

Musonius.

From Seneca we turn, not without satisfaction, to men of sterner mould, such as Musonius Rufus, who certainly deserves a place beside his more illustrious disciple, Epictetus. As a teacher he commanded universal respect, and wherever we catch a glimpse of his activity in these perilous times—whether banished by Nero, or excepted from banishment by Vespasian, as the judicial prosecutor of that foul traitor Egnatius Celer, or as thrusting himself between the ranks of Vespasianists and Vitellianists, to preach conciliation on the eve of a battle—he appears to advantage. His philosophy, however, is yet more concentrated upon practice than Seneca's, and in ethics he is almost at the position of Aristo. Virtue is the sole end, but virtue may be gained without many doctrines, mainly by habit and training. Epictetus testifies to the powerful hold he acquired upon his pupils, each of whom felt as if Musonius spoke to his heart. Amongst a mass of his practical precepts, we come across an original thought, the famous distinction between "things in our power," *i.e.*, our ideas and imaginations, and "things beyond our power," *i.e.*, the course of events and external advantages. The practical lesson drawn from it is, that we must school ourselves to accept willingly the inevitable.

Epictetus.

In the life and teaching of Epictetus this thought bore abundant fruit. The beautiful character which rose superior to weakness, poverty, and slave's estate is also presented to us in the *Discourses* of his disciple Arrian as a model of religious resignation, of forbearance and love towards our brethren, that is, towards all men, since God is our common father. With him even the "physical basis" of ethics takes the form of a religious dogma,—the providence of God and the perfection of the world. We learn that he regards the δαίμων or "guardian angel" as the divine part in each man; sometimes it is more nearly conscience, at other times reason. His ethics, too, has a religious character. He begins with human weakness and man's need of God: whoso would become good must first be convinced that he is evil. Submission is enforced by an argument which almost amounts to a retractation of the difference between things natural and things contrary to nature, as understood by Zeno. Would you be cut off from the universe? he asks. Go to, grow healthy and rich. But if not, if you are a part of it, then become resigned to your lot. Towards this goal of approximation to Cynicism the later Stoics had all along been tending. Withdrawal from the active duty of the world must lead to passive endurance, and, ere long, complete indifference. Musonius had recommended marriage and condemned unsparingly the exposure of infants. Epictetus, however, would have the sage hold aloof from domestic cares, another Cynic trait. So, too, in his great maxim "bear and *forbear*," the last is a command to refrain from the external advantages which nature offers.

Aurelius.

Epictetus is marked out amongst Stoics by his renunciation of the world. He is followed by a Stoic emperor, M. Aurelius Antoninus, who, though in the world, was not of it. The *Meditations* give no systematic exposition of belief, but there are many indications of the religious spirit we have already observed, together with an almost Platonic psychology. Following Epictetus, he speaks of man as a corpse bearing about a soul; at another time he has a threefold division—(1) body, (2) soul, the seat of impulse (πνευματίον), and (3) νοῦς or intelligence, the proper *ego*. In all he writes there is a vein of sadness: the flux of all things, the vanity of life, are thoughts which perpetually recur, along with resignation to the will of God and forbearance towards others, and the religious longing to be rid of the burden and to depart to God. These peculiarities in M. Antoninus may perhaps be explained in harmony with the older Stoic teaching; but, when taken in connexion with the rise of Neoplatonism and the revival of superstition, they are certainly significant. None of the ancient systems fell so rapidly as the Stoa. It had just touched the highest point of practical morality, and in a generation after M. Antoninus there is hardly a professor to be named. Its most valuable lessons to the world were preserved in Christianity; but the grand simplicity of its monism slumbered for fifteen centuries before it was revived by Spinoza.

Literature.—The best modern authority is Zeller, *Phil. d. Griech.*, iii. pt. i. (3d ed., 1880),—Eng. transl. *Stoics*, by Reichel (1879), and *Eclectics*, by S. F. Alleyne (1883). Of the 214 numbers to which the bibliography of Stoicism extends in Ueberweg-Heinze, *Grundriss der Gesch. der Phil.* (7th ed., 1886), may be cited F. Ravaisson, *Essai sur le Stoïcisme*, Paris, 1856; M. Heinze, *Die Lehre vom Logos*, Oldenburg, 1872; H. Siebeck, *Untersuchungen zur Phil. d. Griechen*, Halle, 1873, and *Gesch. d. Psychologie*, i. 2, Gotha, 1884; R. Hirzel, "Die Entwicklung der stoisch. Phil.," in *Untersuchungen zu Ciceros Schriften*, ii. pp. 1–566, Leipsic, 1882; Ogereau, *Essai sur le Système des Stoïciens*, Paris, 1885; L. Stein, *Die Psychologie der Stoa*, i., Berlin, 1886. (R. D. H.)

STOKE-UPON-TRENT, a market-town and municipal and parliamentary borough of Staffordshire, is situated on the Trent, on the Trent and Mersey Canal, where it unites with the Cauldon Canal, and on the London and North-Western and North Staffordshire railway lines, 2 miles east of Newcastle-under-Lyme, and 15 north of Stafford. It is connected with Burslem and other places by steam tramway. The principal public buildings are the town-hall (1835), with assembly rooms, the new market-hall (1883), the Minton memorial building (1858), containing rooms for art and science classes, the free library and museum (1878), and the North Staffordshire infirmary, founded in 1815 and removed to its present site in 1868. A cemetery 21 acres in extent was laid out in 1883. There are statues of Josiah Wedgewood (1863) and of Colin Minton Campbell (1886). The head offices of the North Staffordshire Railway Company are in the town. Stoke has no antiquarian interest, and owes its importance to the porcelain and earthenware manufactures. It may be regarded as the centre of the "Potteries" district. Stoke was created a parliamentary borough in 1832, with two members, but by the Act of 1885 a large part of this went to form the new borough of Hanley. The population of the municipal borough (formed in 1874, with an area of 1660 acres) was 19,261 in 1881; the area has since been increased to 1720 acres. The population of the

parliamentary borough (area 9081 acres) in 1871 was 130,985, and in 1881 it was 152,394; the population of the borough as adjusted in 1885, which returns only one member, is estimated at 65,000.

STOLBERG, or STOLLBERG, an industrial and mining town in Rhenish Prussia, is situated on the Vicht, 7 miles east of Aix-la-Chapelle. It is the centre of a very active and varied industry, exporting its produce to all parts of the world. The leading branch is metal-working, which is here carried on in important zinc, brass, and iron foundries, smelting-works of various kinds, puddling and rolling works, and manufactories of needles, pins, and other metal goods. The ore is mostly found in the mines around the town, but some is imported from a considerable distance. In or near the town there are also large chemical works, glass-works, a mirror-factory, and various minor establishments. Extensive coal mines in the neighbourhood provide the enormous supply of fuel demanded by the various industries. The population in 1885 was 11,841.

The industrial prosperity of the town was founded in the middle of the 17th century by French religious refugees, who introduced the art of brass-founding. An ancient castle in the town is popularly believed to have been a hunting-lodge of Charlemagne.

STOLBERG, COUNT CHRISTIAN (1748–1821), German poet, was born at Hamburg on the 15th October 1748. His father, Count Christian Gunther, was a privy councillor in Denmark. Stolberg studied at Gottingen, where he formed one of a "Dichterbund," which afterwards became famous. It included, besides Stolberg and his brother, Boie, Burger, Miller, Voss, Holty, and Leisewitz. In 1777 he became an official in the civil service at Tremsbuttel in Holstein, and married Louise, the countess of Reventlow, whose beauty he had often celebrated in his verses. He resigned his office in 1800, and afterwards lived upon his estate in Schleswig. He died January 18, 1821.

Stolberg was not a poet of high originality, but in some of his poems he gave vigorous expression to sincere and ardent feeling. He excelled, too, in the utterance of gentle and delicate sentiment. Much of his work appeared in association with that of his brother, whose genius was bolder and more impressive than his own. They published together a volume of poems in 1779, and *Schauspiele mit Chören* in 1787, their object in the latter work being to revive a love for the Greek drama. The dramas contributed to this volume by Christian Stolberg are *Balsazar* and *Otanes*. In 1815 the brothers issued a volume of *Vaterländische Gedichte*. Christian Stolberg was the sole author of *Gedichte aus dem Griechischen* (1782) and of a translation of the works of Sophocles (1787). All his poetical works are included in the *Werke der Brüder Stolberg* (20 vols., 1820–25).

STOLBERG, COUNT FREDERICK LEOPOLD (1750–1819), the brother of the preceding, was born on the 7th November 1750, at Bramstedt in Holstein. Like his brother he studied at Gottingen, and was a member of the "Dichterbund." In 1776 he went to Copenhagen as ambassador of the prince-bishop of Lubeck, and in 1789 he was sent to Berlin as the ambassador of the king of Denmark. His first wife, whom he had married in 1782, having died, he married the Countess Sophia von Redern in 1790, and in the following year he was appointed president of the government of the prince-bishop at Eutin. In 1800 he resigned his office, and at Munster joined the Church of Rome, taking with him all the members of his family except his eldest daughter Agnes, who had married Count Ferdinand von Stolberg-Wernigerode. Stolberg's friends and admirers were astonished by his conversion to the Roman Church, and he was hotly attacked by Voss, whose intervention gave rise to a bitter controversy. After his change of faith Stolberg issued an elaborate *Geschichte der Religion Jesu Christi*, in which he hardly even attempted to write with impartial judgment. He died near Osnabruck on the 5th December 1819.

In association with his brother he published *Gedichte*, *Schauspiele mit Chören*, and *Vaterländische Gedichte*. He also wrote *Jamben* (1784), a series of satires on the vices and prejudices of his time; and he translated the *Iliad*, some of Plato's dialogues, four tragedies of Æschylus, and Ossian's poems. Among his prose writings may be mentioned *Die Insel*, a romance (1788), *Eine Reise in Deutschland, der Schweiz, Italien, und Sicilien* (1794), and his *Leben Alfred's des Grossen* (1815). He was a master of many forms of poetical expression, and in his best period he produced a strong impression on his contemporaries by his passion for nature and freedom.

Biographies of Stolberg have been written by Nicolovius, Menge, Wiedel, Hennes, and Janssen.

STOLP, or STOLPE, an ancient trading town in the bleak coast plain of eastern Pomerania, Prussia, is situated on the Stolpe, 10 miles from the Baltic Sea and 64 miles to the west of Dantzic. The large church of St Mary, with a lofty tower, dating from the 14th century, the Renaissance castle of the 16th century, now used as a prison, and one of the ancient town gates restored in 1872 are memorials of the time when Stolp was a prosperous member of the Hanseatic League. The manufacture of amber articles, tobacco and cigars, cigar-boxes, &c., with some iron-founding, linen-weaving, and salmon-fishing in the Stolpe, are the chief industrial occupations of the inhabitants, who also carry on trade in grain, cattle, spirits, fish, and geese. Stolpmunde, a fishing-village and summer resort, at the mouth of the river, is the port of Stolp. The population of Stolp in 1885 was 22,431 (in 1816 5260), about 600 being Roman Catholics and about 1000 Jews.

Stolp, mentioned in the 11th century, received town rights in 1273. From the 14th to the 16th century it was a member of the Hanseatic League. Until 1637, when it passed to Brandenburg, the town was generally in the possession of the dukes of Pomerania.

STOMACH. See DIGESTIVE ORGANS.

STOMACH, DISEASES OF THE. Only the more common and serious varieties of gastric disease can be here referred to. The majority of them exhibit, as their most marked and sometimes their only feature, the symptoms of DYSPEPSIA (*q.v.*). Hence the diagnosis of the forms of stomach disease is frequently a matter of much difficulty. Nevertheless a careful consideration of the history and the manifested phenomena of a given case may often lead to a correct identification of its nature. The present notice refers in general terms to the most prominent symptoms which usually characterize the chief gastric disorders.

The stomach is liable to inflammatory affections, of which the condition of catarrh, or irritation of its mucous membrane, is the most frequent and most readily recognized. This may exist in an acute or a chronic form, and depends upon some condition either local or general, which produces a congested state of the circulation in the walls of the stomach.

Acute Gastric Catarrh may arise from various causes, of which the most important are—(1) constitutional conditions, such as the gouty or rheumatic, or an inherited tendency to irritability of the digestive organs, (2) errors in diet, particularly excessive quantity, indigestible quality, imperfect mastication, extremes of temperature of the food, toxic agents, especially alcohol, in excess, or food in a state of decomposition, (3) atmospheric influences, as appears evident from its tendency to occur in very warm or very cold weather or in the case of sudden temperature alternations.

The chief change the stomach undergoes affects its mucous membrane, which is in a state of congestion, either throughout or in parts. It is more than probable that this condition produces an alteration in the secreting function of the organ, and that its peptic juices become less potent, the effect of which will be to retard the process of digestion and favour the occurrence of decomposition and fermentation in its contents, thus aggravating the original evil. The symptoms are those well known as characterizing an acute "bilious attack," consisting in loss of appetite, sickness or nausea, and headache, frontal or occipital, often accompanied with giddiness. The tongue is furred, the breath fœtid, and there is pain or discomfort in the region of the stomach, with sour eructations, and frequently vomiting, first of food and then of bilious matter. An attack of this kind tends to subside in a few days, especially if the exciting cause be removed. Sometimes, however, the symptoms recur with such frequency as to lead to the more serious chronic form of the disease.

The treatment bears reference, in the first place, to any known source of irritation, which, if it exist, may be expelled by an emetic or purgative. This, however, is seldom necessary, since vomiting is usually present. For the relief of sickness and pain the sucking

of ice and counter-irritation over the region of the stomach are of service. Further, remedies which exercise a soothing effect upon an irritable mucous membrane, such as bismuth or weak alkaline fluids, and along with these the use of a light milk diet, are usually sufficient to remove the symptoms.

Chronic Gastric Catarrh may result from the acute or may arise independently. It is not unfrequently connected with antecedent disease in other organs, such as the lungs, heart, liver, or kidneys, and it is specially common in persons addicted to alcoholic excess. In this form the texture of the stomach is more seriously affected than in the acute. It is permanently in a state of congestion, and its mucous membrane and muscular coat undergo thickening and other changes, which, besides markedly affecting the function of digestion, may lead to stricture of the pyloric orifice of the stomach and its results, to be subsequently referred to. The symptoms are those of dyspepsia in an aggravated form (see DYSPEPSIA), of which discomfort and pain after food, with distension and frequently vomiting, are the chief, and the treatment must be conducted in reference to the causes giving rise to it. The careful regulation of the diet (see DIETETICS), both as to the amount, the quality, and the intervals between meals, demands special attention. Of medicinal agents, bismuth, arsenic, nux vomica, and the mineral acids are all of acknowledged efficacy, as are also preparations of pepsin.

Ulcer of the Stomach (gastric ulcer, perforating ulcer) is of not unfrequent occurrence, and is a disease of much gravity. Its causes are probably not fully understood, yet the following points may be regarded as generally admitted:—(1) that the disease is twice as common in females as in males, and that it is found to affect domestic servants more frequently than any other class; (2) that it occurs for the most part in early life, the period from twenty to thirty including the great majority of the cases; (3) that it appears to be connected in many instances with impairment of the circulation in the stomach and the formation of a clot in a small blood-vessel (thrombosis); (4) that such an occurrence may arise in connexion with an impoverished state of the blood (anæmia), which is actually the condition present in many of the cases, but that it may also arise from diseased blood-vessels, the result of long continued catarrh, or from the irritation and debilitating effects of hot or cold substances.

It is held that when any such obstruction takes place in a blood-vessel the nutrition of a limited area of the stomach is cut off, and the part is apt to undergo disintegration all the more readily from the unresisted action of the gastric juices upon it. Hence an ulcer is formed. This ulcer is usually of small size (½ to 1 inch in diameter), of round or oval form, and tends to advance, not superficially, but to penetrate through the coats of the stomach. Its most usual site is upon the posterior wall of the upper or lesser curvature of the stomach and near to the pyloric orifice. It may undergo a healing process at any stage, in which case it may leave but little trace of its existence; while, on the other hand, it may in the course of cicatrizing produce such an amount of contraction as to lead to stricture of the pylorus. But, again, perforation may take place, which in most cases is quickly fatal, unless previously the stomach has become, as it may, adherent to another organ, by which the dangerous effects of this occurrence may be averted. Usually there is but one ulcer, but sometimes there are more.

The symptoms to which this disease gives rise are often exceedingly indefinite and obscure, and in some cases the diagnosis has been first made out by the sudden occurrence of a fatal perforation. Generally, however, there are certain evidences more or less distinct which tend to indicate the probable presence of a gastric ulcer. First among these is *pain*, which is in some measure present at all times, but is markedly increased after food. This pain is situated either in front, at the lower end of the sternum, or fully more commonly behind, about the middle of the back. Sometimes it is felt at one or both sides. It is often extremely severe, and is usually accompanied with much tenderness to touch, and also with a sense of oppression and inability to wear tight clothing. The pain is probably largely due to the active movements of the stomach set up by the presence of the food. Accompanying the pain there is frequently *vomiting*, either very soon after the food is swallowed or at a later period. This tends in some measure to relieve the pain and discomfort, and in many instances the patient rather encourages this act. Vomiting of blood (hæmatemesis) is a frequent symptom, and is most important diagnostically. It may show itself either to a slight extent, and in the form of a brown or coffee-like mixture, or as an enormous discharge of pure blood of dark colour and containing clots. The source of the blood is some vessel or vessels which the ulcerative process has ruptured. Blood is also found mixed with the discharges from the bowels, rendering them dark and tarry looking. The general condition of a patient with gastric ulcer is as a rule that of ill-health, showing pallor, more or less emaciation, and debility. The tongue presents a red irritable appearance, and there is usually constipation of the bowels.

The course of a case of gastric ulcer is very variable. In some instances it would appear to be acute, making rapid progress to a favourable or unfavourable termination. In most, however, the disease is chronic, lasting for months or years, and in those cases where the ulcers are multiple or of extensive size incomplete healing may take place and relapses of the symptoms occur from time to time. Ulcers are sometimes present and give rise to no marked symptoms, and it has occurred to the writer to see more than one instance of this kind where fatal perforation suddenly took place, and where *post-mortem* examination revealed the existence of long-standing ulcers which could not possibly have been made out by any evidences furnished during life. While gastric ulcer is always to be regarded as a dangerous disease, its termination, in the great majority of cases, is in recovery. It frequently, however, leaves the stomach in a delicate condition, necessitating the utmost care as regards diet. Occasionally, though rarely, the disease proves fatal by sudden hæmorrhage, but a fatal result is more frequently due to perforation and the extrusion of the contents of the stomach into the peritoneal cavity, in which case death usually occurs in from twelve to forty-eight hours, either from shock or from peritonitis. Should the stomach become adherent to another organ, and fatal perforation be thus prevented, there may remain as the result of this a permanent condition of dyspepsia, owing to interference with the natural movements of the stomach during digestion; while again stricture of the pylorus and consequent dilatation of the stomach is an occasional result of the cicatrization of an ulcer in its neighbourhood.

Of prime importance in the treatment of this disease is the careful adjustment of the diet, the conditions existing in the stomach obviously requiring that the food administered should be of as bland and soft a character as possible. Of all substances milk forms the most suitable aliment, and, while there may be instances in which it fails to agree, even when mixed with lime water or previously boiled, these are comparatively few. The peptonized foods originally suggested by Sir Wm Roberts of Manchester are frequently found of much service in this disease. Light soups as well as milk may sometimes be administered in this way with benefit. The quantity, the intervals between the times of administration, and the temperature, as well as the quantity, of the food demand careful attention. In severe cases, where the presence of food in the stomach gives rise to much suffering, nourishment by the bowel may be given for a time with great advantage. Of medicinal remedies the most serviceable are large doses of bismuth, with which it may be necessary to conjoin small doses of opium or of hydrocyanic acid for the relief of pain. The careful administration of nitrate of silver has been recommended as a means of promoting the healing of the ulcers, but this end is probably more readily accomplished by the remedies and especially by the method of diet already referred to, combined with rest. When hæmorrhage occurs it is relieved by ice and by such styptics as gallic acid, ergot of rye, lead, alum, &c., while in the dread event of perforation the only means of affording relief is opium.

Cancer of the Stomach is one of the most common forms of internal cancerous disease. It occurs for the most part in persons at or after middle life, and in both sexes equally. Hereditary tendency may not unfrequently be traced.

The most common varieties of cancer affecting the stomach are scirrhus, medullary, and colloid, and the parts affected are usually the inlet or outlet orifices, but the morbid process may spread widely in the stomach wall. When in the neighbourhood of the pylorus a stricture is frequently produced as the disease advances. The cancerous growth usually commences in the submucous tissue, but as it progresses it tends to ulcerate through the mucous membrane, and in this process hæmorrhage and hæmatemesis may occur. The symptoms of this disease are in many instances so indefinite as to render the diagnosis for a long time conjectural. They are mostly those of dyspepsia, with more or less pain, discomfort, and vomiting, particularly after meals. The vomited matters are often of coffee-ground appearance, due to admixture with blood, but copious hæmatemesis is less frequent than in cases of gastric ulcer. The patient loses flesh and strength and soon comes to acquire the cachectic aspect commonly associated with cancer. The diagnosis is rendered all the more certain when, as is frequently the case, a tumour can be detected on examination over the region of the stomach, but there are many instances where no such evidence is obtained and where the nature of the disease is left to be made out by the age of the patient and by the intractable and progressive character of the symptoms. Cases of cancer of the stomach advance with more or less rapidity to a fatal termination, which is usually quickest in the medullary form. In most instances death takes place in from six to twelve months. The treatment can only be palliative, but much relief may often be afforded by a careful attention to diet, by the treatment applicable to dilatation of the stomach, and by the use of opium.

Stricture of the Pylorus may, as has been already indicated, result from the various morbid conditions affecting the stomach to which reference has been made, namely, catarrh, ulcer, and cancer. By whatever means produced, the effect is an obstruction to the transmission through the pyloric orifice into the intestines of the contents of the stomach, the occurrence of dilatation of the organ, with

weakening of its walls, and the consequent accumulation and fermentation of partially digested food This condition gives rise to much discomfort, heartburn, and pain, and to the occurrence every few days of a copious vomiting of fermenting material, in which may be found on microscopic examination the fungoid growths of *Sarcina* and *Torulæ* With the continuance of the disease the symptoms tend to increase and to wear out the patient's strength, since little or no assimilation is possible, and death sooner or later takes place from inanition For a long time this condition was regarded as incurable in every case, till the method of treatment, originally suggested by Kussmaul, of washing out the stomach daily or less frequently was found to yield remarkably beneficial results in almost all cases, and, in many instances of non-cancerous disease, to accomplish an actual cure This plan of treatment is now largely resorted to, and it has proved to be a valuable addition to the therapeutics of gastric diseases (J O A)

STONE, a market-town of Staffordshire, England, on the river Trent, and on the North Staffordshire Railway, 7 miles south of Stoke and 7 north of Stafford Part of the walls remain of an abbey which dates from the foundation of a college of canons in 670 The present church was opened in 1750 The inhabitants are employed chiefly in shoemaking, but malting, brewing, and tanning are also carried on The population of the urban sanitary district (estimated area 1000 acres) was 5669 in 1881

STONE See VESICAL DISEASES

STONEHENGE, one of the most remarkable examples of the ancient stone circles, is situated in Salisbury Plain, Wiltshire, about 7 miles north of Salisbury It consists of two circles and two ovals with a large stone in the centre The outer circle, about 300 feet in circumference, is composed of upright stones about 16 feet in height and 18 feet in circumference, with others of similar size placed horizontally on their tops Originally there were thirty uprights and thirty imposts, but now only seventeen uprights and seven imposts retain their position The inner circle, which is about 9 feet distant from the outer circle, consisted originally of forty single stones, much smaller in size, and, unlike those of the outer circle, showing no evidence of having been hewn The larger of the ovals was composed of five pairs of trilithons standing separate from each other, and rising gradually in height from east to west Only two of these now remain entire, one of the uprights of the grand central trilithon has fallen, and is broken in two pieces, the impost though fallen is entire, and the other impost is 9 feet out of the perpendicular, another trilithon fell outward on the 3d June 1797, and of a third one of the uprights is still standing, the other upright and the impost having in their fall been broken into three pieces The inner oval consisted originally of nineteen stones, of which there are remains of eleven, tapering in form and taller than those of the inner circle In the centre of the smaller oval is the supposed altar stone, 15 feet in length The whole is surrounded by a vallum and ditch about 370 yards in circumference From the north-east an avenue, marked by a bank and ditch on each side, proceeds for a distance of 594 yards, after which it divides into two branches, one going eastwards up a hill between two groups of barrows, and the other north-westwards about 300 yards to the cursus or race-course The cursus, which is enclosed between two parallel banks and ditches running east and west, is a mile and 176 yards in length, with a breadth of 110 yards There is a smaller cursus a little to the north In the avenue there is a cromlech or bowing-stone 16 feet in length, called the Friar's Heel, and in a line with it, within the area of the work, there is a large prostrate stone on which it is supposed the victims were immolated Barrows lie around on all sides

Stonehenge is first mentioned by Nennius, in the 9th century, who asserts that it was erected in commemoration of the 400 nobles who were treacherously slain near the spot by Hengist in 472 A similar account of its origin is given in the triads of the Welsh bards, where its erection is attributed to King Merlin, the successor of Vortigern Inigo Jones, in his work on Stonehenge, published in 1655, endeavours to prove that it was a temple of the Romans, but later writers of authority are generally agreed that it is of Druidical origin, although there are differences of opinion as to its probable date, some placing it at 100 years before Christ and others in the 5th century It seems most probable that the inner circle and inner oval, constructed of smaller stones of granite, which must have been brought from a distance, is of earlier origin than the outer circle and oval

Among numerous writings on Stonehenge may be mentioned *Stonehenge and Abury*, by Dr William Stukeley, 1740 reprinted in 1840, Davies s *Celtic Researches*, 1804, and *Mythology of the Druids*, 1809, Hoare s *Ancient Wiltshire*, vol i, 1812, Browne, *An Illustration of Stonehenge and Abury*, 1823, the article on Stonehenge in the *Quarterly Review* for July 1860, Long s *Stonehenge and its Barrows*, 1876, Gidley, *Stonehenge Viewed in the Light of Ancient History and Modern Observation*, 1877

STONE MASONRY See BUILDING, vol iv p 468

STONINGTON, a borough and seaport of the United States, in New London county, Connecticut, is situated on Long Island Sound, 139 miles from New York by the railway to Providence and Boston It is built on a narrow rocky point, and is a quiet quaint-looking town, largely frequented as a summer watering-place Its industries comprise silk-throwing and the manufacture of silk machinery, and it has a considerable interest in sealing Here and there may still be seen traces of the bombardment by the British under Sir Thomas Hardy in August 1814 The harbour is protected by two breakwaters, it is the terminus of a daily line of steamers from New York The population of the township was 6313 in 1870, and 7355 in 1880 Settled in 1649, the borough was incorporated in 1801

STORACE, STEPHEN (1763–1796), dramatic composer, was born in London in 1763 His father, Stefano Storace, an Italian contrabassist, taught him the violin so well that at ten years old he played successfully the most difficult music of the day After completing his education at the Conservatorio di Sant' Onofrio at Naples, he produced his first opera, *Gli Sposi Malcontenti*, at Vienna, in 1785 Here he made the acquaintance of Mozart, in whose *Nozze di Figaro* his sister, Anna Selina Storace, first sang the part of Susanna Here also he produced a second opera, *Gli Equivoci*, founded on Shakespeare's *Comedy of Errors*, and a "Singspiel" entitled *Der Doctor und der Apotheker* But his greatest triumphs were achieved in England, whither he returned in 1787 After creating a favourable impression by bringing out his "Singspiel" at Drury Lane, under the title of *The Doctor and the Apothecary*, Storace attained his first great success in 1789, in *The Haunted Tower*, a genuine English opera, which ran for fifty nights in succession, and retained its popularity long after the opening of the present century *No Song No Supper* was equally successful in 1790, and *The Siege of Belgrade* scarcely less so in 1791 The music of *The Pirates*, produced in 1792, was partly adapted from *Gli Equivoci*, and is remarkable as affording one of the earliest instances of the introduction of a grand *finale* into an English opera These works were followed by some less successful productions, but *The Cherokee* (1794) and *The Three and the Deuce* (1795) were very favourably received, and the music to Colman's play, *The Iron Chest*, first performed March 12, 1796, created even a greater sensation than *The Haunted Tower* This was Storace's last work He caught cold at the rehearsal, and died in consequence, March 19, 1796

The character of Storace's music is pre-eminently English, but his early intercourse with Mozart gave him an immense advantage over his contemporaries in his management of the orchestra, while for the excellence of his method of writing for the voice he was no doubt largely indebted to the charming vocalization of his sister Anna This lady, who has attained lasting honour as the original representative of Susanna in *Le Nozze di Figaro*, was born in London in 1766, completed her education at Venice under Sacchini, sang for Mozart at Vienna, and first appeared at the King's Theatre in London in 1787 After contributing greatly to the success of *The Haunted Tower* and her brother's later operas, she crowned a long and brilliant career by winning great laurels at

the Handel Commemoration at Westminster Abbey in 1791, retired from public life in 1808, and died August 24, 1817 During her stay in Vienna she married John Abraham Fisher, a celebrated violinist, but he used her so cruelly that she refused to bear his name, and in her will—bequeathing property to the amount of £50,000—styled herself "spinster"

STORAX It has been explained in INCENSE (vol xii p 718) and LIQUIDAMBAR (vol xiv p 687) that the storax of commerce and the pharmacopœia (used as an emollient) is derived from the Oriental liquidambar tree The storax of the ancients, on the other hand, a solid gum which does not now occur in commerce, appears to have been the product of the beautiful white-flowered shrub *Styrax officinalis*, which is still common on Carmel and elsewhere in Syria It was much used as an incense, and formed an early and important article of Phœnician trade (see Movers, *Phonizier*, ii 3 101, 223 *sq*) It is probable that the Greek word στύραξ is of Semitic origin, representing the Hebrew צרי, which the English version renders "balm" (Lagarde, *Mittheilungen*, p 234 *sq*)

STORK (A S *Storc*, Germ *Storch*), the *Ciconia alba* of ornithology, and, through picture and story, one of the best known of foreign birds, for, though often visiting Britain, it has never been a native or even inhabitant of the country It is a summer-visitant to most parts of the European continent,—the chief exceptions being France (where the native race has been destroyed), Italy, and Russia,—breeding from southern Sweden to Spain and Greece, and being especially common in Poland [1] It reappears again in Asia Minor, the Caucasus, Persia, and Turkestan, but further to the eastward it is replaced by an allied species, *C boyciana*, which reaches Japan Though occasionally using trees (as was most likely its original habit) for the purpose, the Stork most generally places its nest on buildings,[2] a fact familiar to travellers in Denmark, Holland, and Germany, and it is nearly everywhere a cherished guest, popular belief ascribing good luck to the house to which it attaches itself [3] Its food, consisting mainly of frogs and insects, is gathered in the neighbouring pastures, across which it may be seen stalking with an air of quiet dignity, but in the season of love it indulges in gestures which can only be called grotesque,—leaping from the ground with extended wings in a kind of dance, and, absolutely voiceless as it is, making a loud noise by the clattering of its mandibles At other times it may be seen gravely resting on one leg on an elevated place, thence to sweep aloft and circle with a slow and majestic flight Apart from its considerable size,—and a Stork stands more than three feet in height,—its contrasted plumage of pure white and deep black, with its bright red bill and legs, makes it a conspicuous and beautiful object, especially when seen against the fresh green grass of a luxuriant meadow In winter the Storks of Europe retire to Africa,—some of them, it would seem, reaching the Cape Colony,—while those of Asia visit India A second species, with much the same range, but with none of its relative's domestic disposition, is the Black Stork, *C nigra*, of which the upper parts are black, brilliantly glossed with purple, copper, and green, while it is white beneath,—the bill and legs, with a patch of bare skin round the eyes, being red. This bird breeds in lofty trees, generally those growing in a large forest Two other dark-coloured, but somewhat abnormal, species are the purely African *C abdimii*, and the *C episcopus*, which has a wider range, being found not only in Africa but in India, Java, and Sumatra The New World has only one true Stork, *C maguari*,[4] which inhabits South America, and resembles not a little the *C boyciana* above mentioned, differing therefrom in its greenish-white bill and black tail Both these species are very like *C alba*, but are larger, and have a bare patch of red skin round the eyes

The Storks form the *Pelargi* of Nitzsch, as separated by him from the Herons and the Ibises, but all three are united by Prof Huxley in his group *Pelargomorphæ* The relations of the Storks to the Herons may be doubtful, but there is no doubt that the former include the JABIRU (vol xiii p 529) and its allies, as well as the curious genus *Anastomus* (with its lower mandible hollowed out so as only to meet the maxilla at the base and the tip), of which there are an African and an Asiatic species Two other remarkable forms probably belong to the *Pelargi* These are *Balæniceps rex* and *Scopus*

Shoe-Bill or Whale-Headed Stork (After Wolf in *Trans Zool Soc*)

umbretta, each the sole member of its own genus, and both from Africa The former, first brought to Europe by Mr M Parkyns from the White Nile, was regarded by Gould, who described it in the Zoological *Proceedings* (1851, pp 1, 2, pl xxxv), as an abnormal Pelican This view was disputed by Reinhardt (*op cit*, 1860, p 377), and wholly dispelled by Prof Parker in the Zoological

[1] In that country its numbers are said to have greatly diminished since about 1858, when a disastrous spring-storm overtook the homeward-bound birds The like is to be said of Holland since about 1860

[2] To consult its convenience a stage of some kind, often a cartwheel, is in many places set up and generally occupied by successive generations of tenants

[3] Its common Dutch name is *Ooievaar*, which can be traced through many forms (Koolmann, *Worterb d Ostfries Sprache*, i p 8 *sub voce* "Ådebar") to the old word *Odeboro* ("the bringer of good") In countries where the Stork is abundant it enters largely into popular tales, songs, and proverbs, and from the days of Æsop has been a favourite in fable

[4] This was formerly believed to have occurred in Europe, but erroneously, as was shewn by Schlegel (*Rev Critique*, p 104)

Transactions (iv pp 269–351), though these two authors disagreed as to its affinities, the first placing it with the Storks, the last assigning it to the Herons In singularity of aspect few birds surpass *Balæniceps*, with its gaunt grey figure, some five feet in height, its large head surmounted by a little curled tuft, the scowling expression of its eyes, and its huge bill in form not unlike a whale's head—this last suggesting its generic name—but tipped with a formidable hook The shape of the bill has also prompted the Arabs to call it, according to their idiom, the "Father of a Shoe," and it has been designated "Shoe-bill" in English [1] The other form that remains to be noticed is the *Scopus umbretta* of ornithologists, called the "Umbre" by Pennant This was discovered by Adanson the French traveller in Senegal about the middle of the last century, and was described by Brisson in 1760 It has since been found to inhabit nearly the whole of Africa and Madagascar, and is the "Hammerkop" (Hammerhead) of the Cape colonists Though not larger than a Raven, it builds an enormous nest, some six feet in diameter, with a flat-topped roof and a small hole for entrance and exit, and placed either on a tree or a rocky ledge [2] The bird, of an almost uniform brown colour, slightly glossed with purple, and its tail barred with black, has a long occipital crest, generally borne horizontally, so as to give rise to its common name It is somewhat sluggish by day, but displays much activity at dusk, when it will go through a series of strange performances In all the Storks, so far as is known, the eggs are white, and in most forms distinguishable by the grain of their shell, which, without being rough, is closely pitted with pore-like depressions (A N)

STORMS See METEOROLOGY, vol xvi p 154

STORY, JOSEPH (1779–1845), was born at Marblehead, Massachusetts, September 18, 1779, graduated at Harvard in 1798, and was admitted to the bar in Massachusetts in 1801 He was a member of the Democratic party, then weak in New England but all-powerful in the rest of the Union, and his district made him its representative in Congress for 1808–9 In 1811 one of the associate justiceships of the United States supreme court became vacant, and Story was appointed to it, retaining the office for life Here he found his true sphere of work The traditions of the American people, their strong prejudice for the local supremacy of the States and against a centralized government, had yielded reluctantly to the establishment of the federal legislative and executive in 1789 The federal judiciary had been organized at the same time, but had never grasped the full measure of its powers Soon after Story's appointment the supreme court began to bring out into plain view the powers which the constitution had given it over State courts and State legislation The leading place in this work belongs to Chief-Justice John Marshall, but Story has a very large share in that remarkable series of decisions and opinions, from 1812 until 1832, by which the work was accomplished In addition to this he built up the department of admiralty law in the United States courts, and his *Commentaries on the American Constitution* are still the leading authority on the interpretation of that instrument He died at Cambridge, Massachusetts, where he was the head of the Harvard law school, September 10, 1845

See Story's *Life and Letters of Joseph Story*, Story's *Miscellaneous Works*, Story's *Commentaries on the Constitution of the United States*, and a great number of standard law-books of which he was the author His supreme court decisions are in Cranch's, Wheaton's, and Peters's *Reports*, his circuit decisions in Gallison's, Mason's, Sumner's, and Story's *Reports*

[1] Under one or other of these names it is mentioned by many African travellers, but the best account of it is that given by Von Heuglin (*Orn Nordost Afrika's*, pp 1095–1099) In 1860 two living birds were brought to England by Mr Petherick and exhibited in the Zoological Gardens

[2] Two figures of the nest are given by Holub and Von Pelzeln (*Beitr. Orn Südafrikas*, p 279)

STOTHARD, CHARLES ALFRED (1786–1821), antiquarian draughtsman, son of Thomas Stothard, noticed below, was born in London on July 5, 1786 After studying in the schools of the Royal Academy, he began, in 1810, his first historical piece, the Death of Richard II in Pomfret Castle Having taken a strong interest from an early period in the costumes of different ages and nations, he published in 1811 the first part of his valuable work, *The Monumental Effigies of Great Britain* He was appointed historical draughtsman to the Society of Antiquaries, and was deputed by that body to visit Bayeux, to make drawings of the well-known tapestry He was made a fellow of the society in 1819, and subsequently engaged in numerous journeys with the view of illustrating the works of D Lysons While engaged in tracing a portrait from one of the windows of the church of Beer-Ferrers, Devonshire, he fell and was killed on the spot (May 27, 1821) His widow (afterwards Mrs Bray), along with her brother, completed his *Monumental Effigies*, left unfinished at his death A biography, by his widow, was published in 1823

STOTHARD, THOMAS (1755–1834), subject painter, was born in London on August 17, 1755, the son of a well-to-do innkeeper in Long Acre Being a delicate child, he was sent at the age of five to a relative in Yorkshire, and attended school at Acomb, and afterwards at Tadcastle and at Ilford in Essex Showing a turn for drawing he was apprenticed to a draughtsman of patterns for brocaded silks in Spitalfields, and during his leisure hours he attempted illustrations to the works of his favourite poets Some of these drawings were praised by Harrison, the editor of the *Novelist's Library*, and, Stothard's master having died, he resolved to devote himself to art In 1778 he became a student of the Royal Academy, of which he was elected associate in 1791, full academician in 1794, and librarian in 1817 He married before he was thirty, and it is recorded that, after attending the wedding ceremony, he spent the afternoon in quietly drawing in the schools and, on leaving, requested a fellow student to accompany him "to a family party" "Do come," he said, "for I have this day taken unto myself a wife" He died in London on the 27th of April 1834

Among his earliest book illustrations are plates engraved for *Ossian* and for *Bell's Poets*, and in 1780 he became a regular contributor to the *Novelist's Library*, for which he executed one hundred and forty eight designs, including his eleven admirable illustrations to *Peregrine Pickle* and his graceful subjects from *Clarissa* and *Sir Charles Grandison* Soon his hands were full of work, for all commissions were welcome to him He contentedly designed plates for pocket-books, tickets for concerts, illustrations to almanacs, portraits of popular players,—and into even the slightest and most trivial sketches he infused a grace and distinction which render them of value to the collectors of the present time Among his more important series are the two sets of illustrations to *Robinson Crusoe*, and the plates to *The Pilgrim's Progress* (1788), to *The Rape of the Lock* (1798), to the works of Gessner (1802), to Cowper's *Poems* (1825), and to *The Decameron*, while his figure subjects in the superb editions of Roger's *Italy* (1830) and *Poems* (1834) prove that even in latest age his fancy was still unexhausted and his hand hardly at all enfeebled He is at his best in subjects of a domestic or a gracefully ideal sort, the heroic and the tragic were beyond his powers The designs by Stothard have been estimated by Mr Wornum to number five thousand, and of these about three thousand have been engraved His oil pictures are usually small in size, and rather sketchy in handling Their colouring is often rich and glowing, being founded upon the practice of Rubens, of whom Stothard was a great admirer He was a contributor to Boydell's *Shakespeare Gallery*, but his best known painting is the Procession of the Canterbury Pilgrims, the engraving from which, begun by Schiavonetti and finished by Heath, attained an immense popularity It was followed by a companion work, the Flitch of Bacon, which was drawn in sepia for the engraver, but was never carried out in colour

In addition to his easel pictures Stothard adorned the grand

staircase of Burleigh House with subjects of War, Intemperance, and the Descent of Orpheus in Hell (1799–1803), the mansion of Hafod, North Wales, with a series of scenes from Froissart and Monstrelet (1810), the cupola of the upper hall of the Advocates' Library, Edinburgh (now occupied by the Signet Library), with Apollo and the Muses, and figures of poets, orators, &c (1822), and he prepared designs for a frieze and other decorations for St James's Palace He also designed the magnificent shield presented to the duke of Wellington by the merchants of London, and executed with his own hand a series of eight etchings from the various subjects which adorned it

An interesting, but most indiscriminately eulogistic biography of Stothard, by his daughter in law Mrs Bray, was published in 1851

STOURBRIDGE, a market-town of Worcestershire, England, stands on an eminence on the south bank of the Stour, and on the Great Western Railway, on the borders of Staffordshire, 4 miles south-west of Dudley and 10 west of Birmingham A branch canal connects the town with the Staffordshire and Worcestershire Canal The Stour is crossed by a railway viaduct erected in 1882 at a cost of £13,835 The town possesses a corn exchange, a mechanics' institute, an Edward VI grammar school, a Government school of art, and a blue-coat or hospital school The manufacture of glass was established in 1556 by emigrants from Hungary, the place where they erected their manufactory being still known as Hungary Hill Valuable fire-clay is obtained in the neighbourhood, and a great variety of fine bricks are made There are also large iron and leather works The town was originally called Bedcote, a name which the manor still retains The population of the urban sanitary district (area 450 acres) in 1871 was 9376, and in 1881 it was 9757

STOVES AND FIREPLACES are structures of iron and other materials in which fuel is burned for heating and ventilating apartments and for cooking food Following the primitive open hearth, the first separate heating apparatus used by Egyptians, Greeks, and Romans was the brazier, an open basin of metal in which charcoal was consumed The brazier is still in common use for industrial purposes, and in Continental countries it is widely employed both for cooking and for domestic heating The Romans further were acquainted with the hypocaust, a separate chamber under the floor of the apartment to be heated (see BATHS, vol iii p 434) In an improved form of hypocaust, flues were provided which conveyed the heat and products of combustion to the floors of other apartments at some distance from the fire In the remains of Roman villas found in Britain the hypocaust is an invariable feature The introduction of chimneys into houses in the early part of the 14th century opened the way to all modern improvements in the heating arrangements of apartments, and the efforts of inventors have been devoted to the securing of the thorough combustion of the fuel used, and to the utilization of the maximum amount of heat therefrom in the most healthful and agreeable manner Compare SMOKE ABATEMENT

The stove or close range, as distinguished from the open fireplace, distributes the largest amount of heat from the fuel it burns In its simplest form the common stove consists of a case of iron, closed above, with its sole raised from the floor on which it stands It has two small openings in one side, one on the level of the fire-bars for draught, and the other above for supplying fuel, and on the opposite side the products of combustion are carried away by a flue-pipe passing into a chimney In a more complex form the height of the case or body is increased, and a series of horizontal flues or spaces are formed inside, through which the heated air and smoke pass, thus extracting more thoroughly the heat before it enters the chimney, and giving a greatly increased heating surface Such stoves overdry the air in rooms, and, when they are externally heated to a high degree, floating particles are burned by falling on their surfaces, whence arises the disagreeable stuffy smell almost inseparable from their use To mitigate this evil of overheating, linings of tiles, firebricks, and other non-conducting materials are with great advantage introduced between the heated iron and the air of the apartment In ventilating stoves the outside casing of iron is entirely protected from the direct action of fire by a lining of firebrick The inside is divided into several spaces or flues, and air drawn from without enters by a separate flue, and passing through these spaces is heated and delivered into the apartment as a warm current In another class, of which the gill stove is the type, there radiates from the fire-case a range of flanges or gills a few inches apart, which conduct the heat outwards and enormously extend the heating surface, counteracting at the same time the tendency to overheating Cooking stoves or ranges have in their centre a fire space covered above with a removable top-plate, in which are circular openings whereby the cooking vessels can be brought into direct contact with the fire At both sides there are one or more compartments which form ovens, and around these the heat from the fire is carried by flues, or at one side a water boiler may be placed, although generally a high pressure boiler occupies a space immediately behind the fire The flues which pass around all these spaces, and that also leading directly to the chimney, are controlled by dampers, so that the heat can be directed along any desired course

Both as a heating and cooking agent coal gas is now being largely used, and many forms of stoves have been devised to meet its peculiar conditions as a gaseous fuel Gas stoves present the obvious advantages of cleanliness, comparative freedom from smoke, and immediate readiness for use, and the flame and heat are under the most perfect control Gas is used in open fireplaces as well as in stoves, a most efficient open heating arrangement being that devised by the late Sir Chas W Siemens, in which a combined fire of charcoal and coal gas is made Small lamp stoves for burning mineral oils are also in use, but they share the serious disadvantage of certain simple gas stoves, from which the whole products of combustion pass into the room in which they are placed

Fireplaces are entirely open in front, they radiate heat into the apartment, and flame, smoke, &c, pass direct into the chimney The rapid passage of the heated air into the chimney carries away a large proportion of the heat, and this loss is particularly great in grates made entirely of iron In modern grates of good quality the sides and back of the fire basket are of fire-brick, which retains and throws out much heat In slow-combustion grates the fire-basket is set low on the hearth, and air is admitted to the fuel only through the fire-bars in front The back of the grate slopes in towards the hearth, where the fire space is comparatively narrow By means of a door sliding down over the front from the upper part of the grate, the indraught of air can be modified at pleasure In ventilating fireplaces the fire-basket is of iron lined with fire-brick, and in the space between the back of the grate and the wall flues are formed which are heated from the fire Into these flues air from without is introduced, which, after being there warmed, passes into the apartment at suitable openings

STOW, JOHN (1525–1605), historian and antiquary, was the son of Thomas Stow, a tailor, and was born in London, in the parish of St Michael, Cornhill, in 1525 His parents do not appear to have been rich, for his father's whole rent for his house and garden was only 6s 6d a year, and Stow himself in his youth went every morning to fetch the milk for the family from a farm belonging to the nunnery of Minories He learned the trade of his father, but possibly did not practise it much after he grew up to manhood In 1549 he "kept house" near the well within Aldgate, but afterwards he removed to Lime Street ward, where he resided till his death His first publication was *A Summary of Englysche Chronicles* in 1561, which was frequently reprinted, with slight variations, during his lifetime Of the first edition a copy was said to have been at one time in the Grenville library In the British Museum there are at present copies of the editions of 1567, 1573, 1587, 1590, 1598, and 1604 Stow having in his dedication of 1567 referred to the rival publication of Richard Grafton in contemptuous terms, the dispute between them became extremely embittered Stow's antiquarian tastes brought him under ecclesiastical suspicion as a person "with many dangerous and superstitious books in his possession," and in 1568 Grindal, bishop of London, caused his study to be searched An inventory was taken of certain books he possessed "in defence of Papistry," but he was apparently able to satisfy his interrogators of the soundness of his Protestantism A second attempt to incriminate him in 1570 was also without result In 1580 Stow published his *Annales, or a Generale Chronicle of England from Brute until the present yeare of Christ 1580*, it was reprinted in 1592, 1601, and 1605, the last being continued to the 26th March 1605, or within ten days of

his death, editions "amended" by Howes appeared in 1615 and 1631. The work by which Stow is best known is his *Survey of London*, published in 1598, not only interesting from the quaint simplicity of its style and its amusing descriptions and anecdotes, but of unique value from its minute account of the buildings, social condition, and customs of London in the time of Elizabeth. A second edition appeared in his lifetime in 1603, a third with additions by Anthony Munday in 1618, a fourth by Munday and Dyson in 1633, a fifth with interpolated amendments by Strype in 1720, and a sixth by the same editor in 1754. The edition of 1598 was reprinted, edited by W. J. Thoms, in 1842, in 1846, and with illustrations in 1876. Through the patronage of Archbishop Parker Stow was enabled to print the *Flores Historiarum* of Matthew of Westminster in 1567, the *Chronicle* of Matthew Paris in 1571, and the *Historia Brevis* of Thomas Walsingham in 1574. At the request of Parker he had himself compiled a "farre larger volume," but circumstances were unfavourable to its publication and the manuscript is now lost. Additions to the previously published works of Chaucer were twice made through Stow's "own painful labours" in editions of 1561 and 1597. A number of Stow's manuscripts are in the Harleian collection in the British Museum. Some are in the Lambeth Library (No. 306), and from the volume which includes them were published by the Camden Society, edited by James Gairdner, *Three Fifteenth-Century Chronicles, with Historical Memoranda by John Stowe the Antiquary, and Contemporary Notes of Occurrences written by him* (1880). Stow's literary labours did not prove very remunerative, but he accepted poverty in a cheerful spirit. Ben Jonson relates that once when walking with him Stow jocularly asked two mendicant cripples "what they would have to take him to their order." This favour he, however, obtained from King James, who in March 1604 authorized him and his deputies to collect "amongst our loving subjects their voluntary contributions and kind gratuities," and himself began "the largesse for the example of others." If the royal appeal was successful Stow did not live long to enjoy the increased comfort resulting from it, as he died on the 6th April following. He was buried in the church of St Andrew Undershaft, where the monument erected by his widow, exhibiting a terra-cotta figure of him, still remains.

STOWELL, WILLIAM SCOTT, BARON (1745–1836), one of the ablest and most accomplished of English judges, especially in international law, was born at Heworth, a village about four miles from Newcastle, on 17th October 1745. His father was a "coalfitter" (or tradesman engaged in the transport of coal); his mother was the daughter of a small tradesman, Atkinson by name; his younger brother John became the famous Lord Chancellor ELDON (*q.v.*). Scott was educated at the Newcastle grammar school under the able tuition of the Rev. Hugh Moises. In February 1761 he gained a Durham scholarship at Corpus Christi College, Oxford, and was immediately admitted as a student of the university. In 1764 he graduated as bachelor of arts, and became first a probationary fellow and then—as successor to William (afterwards the well known Sir William) Jones—a tutor of University College. In 1767 he took his M.A. degree. In 1772 he graduated as bachelor of civil law. As Camden reader of ancient history he rivalled the reputation of Blackstone (1774). Although he had joined the Middle Temple in 1762 (June 24), it was not till 1776 that Scott devoted himself to a systematic study of law. In 1779 (June 23) he graduated as doctor of civil law, and, after the customary "year of silence," commenced practice in the ecclesiastical courts. His professional success was rapid. In 1783 he became registrar of the Court of Faculties, and in 1788 judge of the Consistory Court and advocate-general, in that year too receiving the honour of knighthood; and in 1798 he was made judge of the High Court of Admiralty. Sir William Scott twice contested the representation of Oxford university,—in 1780 without success, but successfully in 1801. He also sat for Downton in 1790. Upon the coronation of George IV. (1821) he was raised to the peerage as Baron Stowell. After a life of distinguished judicial service Lord Stowell retired from the bench,—from the Consistory Court in August 1821, and from the High Court of Admiralty in December 1827. His mental faculties became gradually feebler in his old age, and he died on January 28, 1836. Lord Stowell was twice married,—on April 7, 1781, to Anna Maria, eldest daughter and heiress of John Bagnall of Early Court, Berks, and on April 10, 1813, to the dowager marchioness of Sligo. By his first marriage he had four children, of whom two (a son and a daughter) died in infancy, a third (a son) died unmarried in middle life, while the eldest (a daughter) was twice married and survived her father.

Lord Stowell's judgments are models alike of literary execution and of judicial reasoning. His style is chaste yet not inornate, nervous without abruptness, and perfectly adjusted in every instance to the subject with which he deals. His decisions in the cases of Dalrymple *v.* Dalrymple (Dr Dodson's *Report*) and Evans *v.* Evans (1 Hagg., 35)—from their combined force and grace, from the steadiness with which every collateral issue is set aside, from their subtle insight into human motives, and from the light which they cast on the philosophy and dark history of marriage law—deserve and will repay attentive perusal. Lord Stowell composed with great care, and some of the MSS. which he revised for Haggard and Phillimore's *Reports* were as full of interlineations as a bill of the Lower House corrected by the Lords. Stowell's mind was judicial rather than forensic,—reasoning, not as for a dialectic victory nor so as to convince the parties on whose suit he was deciding, but only with sufficient clearness, fulness, and force to justify the decision at which he had arrived.

The chief doctrines of international law with the assertion and illustration of which the name of Lord Stowell is identified are these:—the perfect equality and entire independence of all states (Le Louis, 2 Dod., 243)—a logical deduction from the Austinian philosophy and still one of the fundamental principles of English jurisprudence; that the elementary rules of international law bind even semi-barbarous states (Hurtige Hans, 2 Rob., 325); that blockade to be binding must be effectual (The "Betsoy," 1 Rob., 93), that there cannot be a legal where there is no actual blockade; and that contraband of war is to be determined by "probable destination" (The "Jonge Margaretha," 1 Rob., 189). In the famous Swedish convoy case (The "Maria," 1 Rob., 350; see too The "Recovery," 6 C. Rob., 348–9) Lord Stowell, in defiance of the complaints of those greedy merchants who, as Pufendorf, himself by choice a Swedish civilian, tells us, cared not how things went provided they could but satisfy their thirst of gain, asserted that "a prize court is a court not merely of the country in which it sits but of the law of nations." "The seat of judicial authority," he added, in words which have become classic, "is indeed locally here, in the belligerent country, but the law itself has no locality."

The judgments of Lord Stowell were, almost without exception, confirmed on appeal, are to this day the international law of England, and have become presumptive though not conclusive evidence of the international law of America. "I have taken care," wrote Justice Story, "that they shall form the basis of the maritime law of the United States, and I have no hesitation in saying that they ought to do so in that of every civilized country in the world."

STRABISMUS. See OPHTHALMOLOGY, vol. xvii. p. 785.

STRABO, the famous geographer and historian, was born at Amasea in Pontus, a city which had been Hellenized to a great extent. Of his father's family we know nothing; but several of his mother's relations, who were probably Greeks, had held important posts under Mithradates Euergetes and his famous son Mithradates Eupator. Dorylaus, a distinguished general of Mithradates Euergetes, was the great-grandfather of Strabo's mother. After the murder of that king, Dorylaus, who at that time was collecting mercenaries in Crete, where he had obtained the command

in a successful war of the Cnossians against Gortyn, settled at Cnossus By Sterope, a Macedonian, he had a daughter and two sons,—Lagetas and Stratarchus Dorylaus had a brother Philetærus, whose son Dorylaus was brought up with Mithradates Eupator This king, at the instance of his friend invited back to Pontus the family of Dorylaus, who was himself now dead, as was also his son Lagetas Strabo saw Stratarchus in extreme old age The daughter of Lagetas was the mother of Strabo's mother Moaphernes, an uncle of Strabo's mother, probably on the father's side, was governor of Colchis under Mithradates Eupator His mother's father must have held an important position, for, seeing the impending downfall of the king, and also in anger against him for having put to death his kinsmen Tibius and Theophilus, he handed over fifteen forts to Lucullus In spite of this, with the ruin of the king the fortunes of the family fell, since Pompey refused to ratify the rewards promised by Lucullus

Life—Though the exact date of Strabo's birth is unknown, a close approximation is possible Clinton places it not later than 54 B C The most probable date lies between 64 and 62, since he speaks of certain events occurring at the former as "a little before my time," whilst he describes an occurrence in the latter year as "in my own time," phrases which he uses elsewhere with great exactness in speaking of persons and events He received a good education in the Greek poets, especially Homer, he studied at Nysa under the grammarian Aristodemus, under Tyrannio the grammarian at Rome, under the philosopher Xenarchus either at Rome or Alexandria, and he had studied Aristotle along with Boethus (possibly at Rome under Tyrannio, who had access to the Aristotelian writings in Sulla's library) It is to be noted that from none of those teachers was he likely to learn mathematics or astronomy He was at Corinth in 29 B C, where he saw Octavian on his return from Egypt to celebrate his triumph for Actium He was in Egypt in 24 B C, and took the opportunity of ascending the Nile in company with the prefect Ælius Gallus He was at Rome after 14 A D, for he describes (v 236) as an eyewitness the place where the body of Augustus was burnt in the Campus He was still writing in 21 A D The date of his death is unknown Strabo's statement that he saw P Servilius Isauricus has caused some difficulty This Servilius died at Rome in 44 B C at an advanced age Some suppose that Strabo confused him with P Servilius Casca, also called Isauricus, or some other distinguished Roman whom he had seen in Asia, but by his words he clearly means the conqueror of the Isaurians This difficulty only arises from an entirely unwarranted assumption that Strabo was on his way to Rome for the first time in 29 B C We have seen that he studied under Tyrannio in that city, if he did so after 29 B C Tyrannio must have been very old, which Strabo would probably have mentioned, as he does in the case of Aristodemus Although he had seen a comparatively small portion of the regions which he describes, he had travelled much, as he states himself "Westward I have journeyed to the parts of Etruria opposite Sardinia, towards the south from the Euxine to the borders of Ethiopia, and perhaps not one of those who have written geographies has visited more places than I have between those limits For those who have gone farther west have not gone so far eastward, and the case is the same with the regions between the northern and southern limits" The fulness of his description in certain places, contrasted with the meagreness and inaccuracy in others, seems to indicate that in the former cases he had actually visited the places, but that he is dependent on second-hand information for the latter He tells us that he had seen Egypt as far south as Syene and Philæ, Comana in Cappadocia, Ephesus, Mylasa, Nysa and Hierapolis in Phrygia, Gyarus, and Populonia Of Greece proper he saw but little, he visited Corinth, Athens, Megara, and places in their vicinity, and perhaps Argos, although he was not aware that the ruins of Mycenæ still existed, he had seen Cyrene from the sea, probably on his voyage from Puteoli to Alexandria He remained at the latter place a long time, probably amassing materials, and studying astronomy and mathematics For nowhere could he have had a better means of consulting the works of historians, geographers, and astronomers, such as Eratosthenes, Posidonius, Hipparchus, and Apollodorus When and where he went from Egypt we know not It has been commonly assumed that he returned home to Amasea For this there are no grounds Probabilities are in favour of his having returned to Rome, where he undoubtedly resided in his old age The place of his death is unknown, but, since we find him at Rome in what must in the course of nature have been the closing years of his life, it is not unreasonable to suppose that there he died Various passages in his work indicate that he held by the Stoic rule

Works—His earliest writings were two (not one, as commonly stated) historical works now lost, which he himself describes (xi 515) as his *Historical Memoirs* and his *Continuation of Polybius* There can be no doubt but that these were two distinct works, for he speaks (ii 70) of having treated of the exploits of Alexander in his *Memoirs*, a topic which could not have found a place in a work which began where that of Polybius ended (146 B C) According to Suidas, the continuation of Polybius was in forty-three books Plutarch, who calls him "the Philosopher," quotes Strabo's *Memoirs* (*Luc*, 28), and cites him as an historian (*Sulla*, 26) Josephus, who constantly calls him "the Cappadocian," often quotes from him, but does not mention the title of the work

The *Geography* is the most important work on that science which antiquity has left us It was, as far as we know, the first attempt to collect all the geographical knowledge at the time attainable, and to compose a general treatise on geography It must not be regarded as nothing more than a new edition of Eratosthenes In general outline it follows necessarily the work of the last-named geographer, who had first laid down a scientific basis for geography on which his successors could not help building Strabo made considerable alterations, but not always for the better The three books of the older work formed a strictly technical geographical treatise Its small size prevented it from containing any such general description of separate countries as Strabo rightly conceived to fall within the scope of the geographer "Strabo indeed appears to be the first who conceived a complete geographical treatise as comprising the four divisions of mathematical, physical, political, and historical geography, and he endeavoured, however imperfectly, to keep all these objects in view" Moreover, the incidental historical notices, which are often of great value and interest, are all his own These digressions at times interrupt the symmetry of his plan, but Strabo had all the Greek love of legendary lore, and he discusses questions relating to the journeyings of Heracles as earnestly as if they were events within recent history He regarded Homer as the source of all wisdom and knowledge, and consequently accepted the Homeric geography in its entirety, as needing only proper explanation for the removal of all difficulties. On the other hand, he treats the work of Herodotus with undeserved contempt, and classes him with Ctesias and other "marvel-mongers", and yet in some respects Herodotus had better information—for instance, in regard to the Caspian—than that possessed by Strabo himself

Again, Strabo may be censured for discarding the statements of Pytheas respecting the west and north of Europe, accepted as they had been by Eratosthenes. But in this he relied on Polybius, whom he might justly consider as having from his position at Rome far better means of gaining accurate information about those regions. A critical sagacity far stronger than that of Strabo might well have erred at a time when the data for forming accurate judgments on such questions were so meagre and chaotic. It must be admitted that the statements of Pytheas did not accord with the theory of Strabo just in those very points where he was at variance with Eratosthenes. He showed likewise an unwarranted scepticism in reference to the island of Cerne on the west coast of Africa, which without doubt the Carthaginians had long used as an emporium. Strabo has been censured for not making a greater use of Roman authorities. Although the Roman arms had opened up much of the north and west, he follows the Greek writers almost exclusively in his description of Spain, Gaul, Britain, Germany, and even Italy. For, although he refers to Cæsar's *Commentaries* once by name, and has evidently made use of them in other passages, he but imperfectly availed himself of that work. He designed his geography as a sequel to his historical writings, and it had as it were grown out of his historical materials. Such materials were chiefly Greek. We cannot wonder if a man who at an advanced age has commenced a new work utilizes his old material, and has not the energy to undertake fresh researches. Again, if Strabo amassed his material in the library of Alexandria, Greek authorities would naturally furnish the great bulk of his collections. This involves the questions—When and where did he compose the work? He began it probably later than 9 B.C. For he says that, just as Alexander had opened up knowledge of the East, so the Roman arms had now opened up the geography of the West as far as the Elbe. This Drusus accomplished in 9 B.C. Strabo was still engaged on the work, or certain parts of it, in 19 A.D., for he mentions in the fourth book the conquest of the Taurisci as having taken place thirty-three years before; he also speaks, in the sixth book, of Germanicus, who died in 20 A.D., as still alive, and in the seventeenth book he speaks of the death of Juba II. (21 A.D.) as a recent event. As it is not probable that he wrote for the first time all of his work except the first three books between 19 and 21 A.D., we must not make use of these passages as data for determining the date of composition of the whole work, or even of particular books, but rather ought we to regard them as insertions. Strabo, as already pointed out, was at Rome after the death of Augustus (14 A.D.); in book vii. 290 and in book xiii. 609 he uses the terms "here" and "hither" in reference to Rome. It may be inferred from these passages that Strabo certainly revised, if he did not write, the entire work at Rome. If he returned to Rome after a long sojourn in Alexandria, this explains the defectiveness of his information about the countries to the east of his native land, and renders it possible for him to have made use of the chorography of Agrippa, and to have obtained the few incidents from Roman sources which here and there appear in his work.

He designed the work for the statesman rather than for the student. He therefore endeavours to give a general sketch of the character, physical peculiarities, and natural productions of each country, and consequently gives us much valuable information respecting ethnology, trade, and metallurgy. It was almost necessary that in such an attempt he should select what he thought most important for description, and at times omit what we deem of more importance. With respect to physical geography, his work is a great advance on all preceding ones. Judged by modern standards, his description of the direction of rivers and mountain-chains seems defective, but allowance must be made for difficulties in procuring information, and for want of accurate instruments. In respect of mathematical geography, his want of high scientific training was of no great hindrance. He had before him the results of Eratosthenes, Hipparchus, and Posidonius. The chief conclusions of astronomers concerning the spherical figure and dimensions of the earth, its relation to the heavenly bodies, and the great circles of the globe—the equator, the ecliptic, and the tropics—were considered as well established. He accepted also the division into five zones; he quotes approvingly the assertion of Hipparchus that it was impossible to make real advances in geography without astronomical observations for determining latitudes and longitudes.

The work consists of seventeen books, of which the seventh is imperfect. The first two books form a general introduction; the next ten deal with Europe, the four following with Asia, and the last with Africa. The first two books are meant to comprise a general survey of the progress of geography from the earliest times down to his own day. Unmethodical though they are, we owe to these books almost all we know of the geographical systems of his predecessors, especially that of Eratosthenes. Unfortunately he contents himself with disjointed criticism of detail instead of giving us an orderly statement of the previous systems. The first book begins with his claim to have geography regarded as a branch of philosophy, and he supports this claim by enumerating the philosophers who have studied it, beginning from Homer, as proofs of whose knowledge he adduces his acquaintance with the Ocean, the Ethiopians, and the Scythians. This discussion of Homer's geography takes up more than half the book. Passing over the early geographers, not even mentioning Herodotus, he censures Eratosthenes for using unreliable authorities, and for casting doubts on the voyages of Jason and other early navigators. He next criticizes the physical views of Eratosthenes concerning the changes in the earth's surface, and especially the hypothesis, adopted from Strato, that by sudden disruptions of land the Euxine and Mediterranean had become united to the ocean, and had sunk to their present level, which theory they supported by pointing to sea shells at places high above the sea. This doctrine Strabo rightly rejected, and referred such phenomena to those changes which with constant operation produce subsidences and elevations of the land; and he quotes many instances of places engulfed by earthquakes, the disappearance of some islands, and the appearing of others. Hence he thinks it possible that even Sicily has been thrown up by the fires of Etna. Sir C. Lyell eulogizes Strabo's geological speculations for a soundness of view very unusual on such subjects amongst the ancients. Examining the second book of Eratosthenes, he discusses the length and breadth of the inhabited world, and its division into three continents. He blames Eratosthenes for believing Pytheas, and denies the existence of Thule, consequently rejecting the latitude assigned to it by Eratosthenes, who had taken it as the northernmost limit of the inhabited world. Strabo holds Ierne (Ireland), which lies north of Britain, to be the farthest land in that direction, and brings the northern limit much farther south. As he adopts Eratosthenes's southern limit,—that through the Cinnamon Region and Taprobane (Ceylon),—it follows that in his view Eratosthenes had made the inhabited world too broad. As the Greeks assumed that the world was twice as long as it was broad, Eratosthenes accordingly had made it too long likewise; but, though Strabo shortens it on the west, there is no material difference between him and Eratosthenes. In this connexion he gives his remarkable speculation that, as the inhabited world was only one third of the globe's circumference, there might be two or more inhabited worlds besides. In the second book he discusses the changes introduced by Eratosthenes, and rightly defends him from the attacks of Hipparchus. He adopts for Asia the map of Eratosthenes as a whole, for little additional knowledge had been gained in the interval. He even still regards the Caspian as opening into the Northern Ocean, as stated by Patrocles. In the general outline of Africa he makes no change, but he rejects the statement of Eratosthenes about Cerne. It is with respect to western and northern Europe that Strabo had knowledge denied to Eratosthenes. Roman conquest had opened up many places and peoples, yet his general map of Europe is inferior to that of his predecessor. After discussing the "seals" of Eratosthenes, he considers the views of Posidonius and Polybius, and recounts the voyages of Eudoxus of Cyzicus. Then having dealt with the division into zones, due to Parmenides, he states his own views, discussing briefly the mathematical geography: the earth is spherical and placed in the centre of the universe; he assumes five zones, and the circles on the sphere—the equator, the ecliptic or

zodiac, the tropics, and the arctic circles; he assumes the earth's circumference as given by Eratosthenes, 252,000 stades (=25,200 geographical miles), and his division of the great circle into sixtieth parts; the habitable world, the geographer's proper province, shaped like a chlamys, occupies a quadrilateral space in the northern hemisphere, filling little more than one-third of the north temperate zone; its maximum length is 70,000 stades, its breadth less than 30,000 stades. Whilst correcting the error by which his predecessors placed Massilia and Byzantium in the same latitude, he falls into an equal mistake by placing the former city two degrees south, instead of two degrees north of Byzantium. As Massilia is his cardinal point for measurements, this error distorts his whole map of the Mediterranean and western Europe, the mouths of the Rhine and Danube being in the same latitude. He next gives directions for making a plane map of the world, as a globe of sufficient size, like that of Crates, is too cumbrous. All lines that are circles on a globe must be straight lines on the map. Before describing each country in detail, he gives a general sketch of the habitable world with reference to seas, continents, and peoples, and explains the doctrine of climate and of the shadows projected by objects in consequence of the sun's varying position with respect to them. In the third book, starting from the Straits, he begins his description with Iberia, which he likens in shape to a bull's hide. His chief authorities were Artemidorus, whom he uses for the coasts of the Mediterranean and ocean generally, Eratosthenes, Posidonius, Polybius, Pherecydes, Timosthenes, Asclepiades, Myrleanus, and Dicæarchus. He gives a valuable account of the Roman administrative system, probably gained from his own inquiries, also of the native tribes, of the mines and methods of mining, and of the remains of the Greek and Phœnician settlements; he describes the Balearic Isles, following Artemidorus, and at the end of the book mentions the Cassiterides, which he seems to have identified with the Scilly Isles, probably erroneously, and describes their inhabitants as wearing long black garments, and walking about with long wands in their hands, looking like the Furies of tragedy. It is remarkable that he has no notion of the proximity of the Tin Islands to Britain, but treats them in connexion with Spain. The fourth book deals with Gaul in its fourfold division under Augustus, gives a meagre account of Britain, its trade and relations with Rome, and mentions Ireland, the natives of which were said to be cannibals and to hold their women in common, and finally treats of the Alps. His authorities were Posidonius, who had travelled in Gaul and Britain, Artemidorus, Ephorus, Timagenes, Aristotle, Polybius, Asinius Pollio, and Cæsar. For Britain Pytheas, as quoted by others, furnished some important details. His description of Gallia Narbonensis is fuller than that of the rest of Gaul. He mentions the four great Roman roads converging at Lyons, probably following the chorography of Agrippa. He conceives the Pyrenees as running north and south, and parallel to the Rhine, and Britain as lying north of Gaul, extending from the Pyrenees to the Rhine's mouths. Of the Alpine region he gives an excellent description. He undoubtedly must have gathered much information for this book at Rome. The fifth and sixth books contain an accurate description of Italy and the adjacent islands. Besides his own observation he used Eratosthenes, Polybius, Artemidorus, Ephorus, Fabius Pictor, Cœlius, Antiochus of Syracuse for southern Italy, and the "chorographer," who was certainly a Roman, as he gave his distances in miles, and who probably was Agrippa, the chief objection to such an authorship being the wrong assumption that Strabo was not in Italy after 24 B.C., whilst Agrippa's work was not published until after his death 12 B.C. The sixth book ends with a short but valuable sketch of the extent and condition of the Roman empire. The seventh comprises northern and eastern Europe, both north and south of the Danube, Illyricum, Pannonia, Dalmatia, the coast of Thrace and the Euxine, and Epirus. The part which dealt with Macedonia and Thrace is only known to us from the epitomes. We do not know his authorities for the German tribes, but he probably used Roman materials. For the other northern tribes he had Posidonius, whilst for the region south of the Danube he had Aristotle's lost work on *Polities*, Polybius, Posidonius, Theopompus, and Ephorus. The eighth, ninth, and tenth books contain his description of the mainland of Greece and the islands, which he treats rather as an antiquarian than a geographer, using chiefly, besides Homer, Apollodorus, Demetrius of Scepsis, Ephorus, and Eudoxus. Personally he had but little knowledge. With the eleventh begins Asia. Divided from Europe by the Don, it is split up into two large masses by the Taurus. Beginning with the region bounded by the Taurus, Caspian, and Euxine, he next describes the part east of the Caspian, then those south of the Caucasus, Media, and Armenia. His authorities are Artemidorus, Eratosthenes, Theophanes, Herodotus, Apollodorus of Artemita, Patrocles, Metrodorus of Scepsis, Hypsicrates of Amisus, Posidonius, and Aristobulus. In the twelfth he describes Asia Minor, basing his description on oral information, personal observation, and the Greek writers. In the thirteenth he continues with Asia Minor, devoting much space to the Troad, his sources being Demetrius, Menecrates, and the Greek mythographers. With the fourteenth he ends Asia Minor and the islands lying off it, using, in addition to the authorities for the last, Pherecydes, Thucydides, Anaximenes of Lampsacus, Herodotus, Ephorus, Artemidorus, Eratosthenes, and Posidonius. The fifteenth deals with India and Persia, giving much valuable information from Patrocles, Aristobulus, Nearchus, the historians of the campaigns of Alexander and Seleucus, and with reserve from Megasthenes, Onesicritus, Deimachus, and Clitarchus. In the sixteenth he treats of Assyria, under which he includes Babylonia and Mesopotamia, Syria, Phœnicia, Palestine, the Persian Gulf, the Red Sea and the coast of Ethiopia, and Arabia. For Asia he used the historians of Alexander, Eratosthenes and Herodotus, for Judæa and Syria probably Posidonius, himself a native of Apamea, for Arabia and the coast of Libya Eratosthenes and Artemidorus, the latter of whom followed Agatharchides of Cnidus. Strabo must have got many details about Arabia from Ælius Gallus and the Stoic Athenodorus. The last book comprises Egypt, Ethiopia, and the north coast of Libya. He describes Egypt from his own observation, having gained much information at Alexandria in addition to that of Eudoxus, Aristo, Eratosthenes, Polybius, and Posidonius, using the last three with the addition of Iphicrates for Libya, and for Ethiopia Petronius, Herodotus, and Agatharchides. Though probably acquainted with the work of Juba, he did not make much use of it. The book concludes with a summary of the provinces of the Roman empire, as organized by Augustus into senatorial and imperial.

EDITIONS.—Aldus, Venice, 1516; Hopper and Heresbach, Basel, 1549; Xylander, Basel, 1571; Casaubon, Geneva, 1587, Paris, 1620 (Casaubon revised the text); Almeloveen, Amsterdam, 1707, reprinted Casaubon's text; Falconer, Oxford, 1807, reprinted Almeloveen's text; Siebenkees and Tzschucke, Leipsic, 1811; Koray, Paris, 1815-18, the first really critical edition; Kramer, Berlin, 1844-52; C. Muller, Paris, 1853; Meineke, Leipsic, 1877. TRANSLATIONS.—*Latin*: Guarini and Gregorio, 1471; Xylander, 1571. *French*: Koray and Letronne, 1805-19. *German*: Groskurd, 1833 (with dissertations). *Italian*: Ambrosoli, 1828. DISSERTATIONS, &c.—Bunbury, *Ancient Geography*; Heeren; Hasenmuller; Niese, *Hermes*, 1878. (W. RI.)

STRADELLA, ALESSANDRO, composer, singer, and performer on various instruments, was one of the most accomplished Italian musicians of the 17th century. The generally accepted statement that he was born at Naples about 1645 rests upon no trustworthy foundation; and the few biographical notices that we possess savour so strongly of romance that we can only be said to know him truly through his works, which show extraordinary genius, and have exercised a highly beneficial influence upon Italian art. The story of his life was first circumstantially narrated in Bonnet-Bourdelot's *Histoire de la Musique et de ses Effets* (Paris, 1715). According to this account, Stradella not only produced some successful operas at Venice, but also attained so great a reputation by the beauty of his voice that a Venetian nobleman engaged him to instruct his mistress, Ortensia, in singing. Stradella, the narrative goes on to say, shamefully betrayed his trust, and eloped with Ortensia to Rome, whither the outraged Venetian sent two paid *bravi* to put him to death. On their arrival in Rome the assassins learned that Stradella had just completed a new oratorio, over the performance of which he was to preside on the following day at S. Giovanni in Laterano. Taking advantage of this circumstance, they determined to kill him as he left the church; but the beauty of the music affected them so deeply that their hearts failed them at the critical moment, and, confessing their treachery, they entreated the composer to ensure his safety by quitting Rome immediately. Thereupon Stradella fled with Ortensia to Turin, where, notwithstanding the favour shown to him by the regent of Savoy, he was attacked one night by another band of assassins, who, headed by Ortensia's father, left him on the ramparts for dead. Through the connivance of the French ambassador the ruffians succeeded in making their escape; and in the meantime Stradella, recovering from his wounds, married Ortensia, by consent of the regent, and removed with her to Genoa. Here he believed himself safe; but a year later he and Ortensia were murdered in their house by a third party of assassins in the pay of the implacable Venetian.

Bonnet-Bourdelot gives 1670 as the date at which the assassination actually took place; but the oratorio *San Giovanni Battista*, assumed to be that which saved its author's life, is dated "Roma,

1676", and a cantata, called *Il Barcheggio*, is known to have been composed by Stradella for the marriage of Carlo Spinola and Paola Brignolo in 1681 These discrepancies are not, however, of sufficient moment to justify the rejection of Bonnet-Bourdelot's account, which has been accepted as genuine by Burney, Hawkins, Fétis, and many other careful writers, including the remarkably accurate and conscientious Wanley [1] And it must be remembered, in its defence, that Pierre Bourdelot, by whom the materials for the *Histoire de la Musique et de ses Effets* were originally compiled, was an actual contemporary of Stradella, and died as early as 1685, when a host of the composer's friends must still have been living, and able to give evidence on the subject of his fate It seems therefore only reasonable to assume that the main facts of the narrative are correctly given, though the dates may need confirmation, while for the embroidered versions of later writers the authors of the *Histoire* are certainly not responsible

The finest collection of Stradella's works extant is that at the Biblioteca Palatina at Modena, which contains 148 MSS, including eleven operas and six oratorios A collection of *canti a voce sola* was bequeathed by the Contarini family to the library of St Mark at Venice, and some MSS are also preserved at Naples and in Paris Eight madrigals, three duets, and a sonata for two violins and bass will be found among the Additional MSS at the British Museum, five pieces among the Harleian MSS, and eight cantatas and a motet among those in the library at Christ Church, Oxford Very few of these compositions have been published, but an extremely beautiful *aria di chiesa*, entitled *Pietà Signore*,[2] has been frequently printed, under the name of Stradella, and popularly accepted as the air which produced so marvellous an effect upon the assassins The piece, however, is not to be found in *San Giovanni Battista*, and its style so little resembles that of Stradella's other works that no less decisive evidence than the discovery of an undoubted autograph could justify its ascription to him On the other hand, no more extravagant mistake could be made than that of describing it, as some have done, as a forgery, perpetrated either by Fétis, Rossini, or Niedermeyer Not one of these great musicians could have written it, and it is certainly no forgery, but a genuine work of the 17th century or the opening decade of the 18th In the absence of trustworthy documentary evidence, all attempts to ascertain the real authorship of the piece must necessarily end in mere conjecture, but the extraordinary similarity of its style to that cultivated by Francesco de' Rossi, who is known to have been flourishing at Bari at the time of Stradella's death, is very significant

Much controversy has also been excited by another work, lately attributed to Stradella, viz, a *serenata* for voices and instruments, of which two copies only are known to exist,—one at the Conservatoire at Paris, and the other, a late transcript, now at the Royal College of Music in London The date of this *serenata* is absolutely unknown Of evidence proving it to be a genuine work by Stradella there is none in existence Yet the question of its authenticity is a most important one, for upon the strength of it Handel may perhaps be some day gravely accused of having stolen from the Italian composer some of the finest passages in *Israel in Egypt*

The compositions of Stradella are remarkable for their graceful form and the tenderness of their expression Detached movements will be found in Burney's *History of Music* and the modern collection called *Gemme d'Antichità*

STRADIVARIUS See VIOLIN

STRAFFORD, THOMAS WENTWORTH, EARL OF (1593–1641), son of Sir William Wentworth, of Wentworth Woodhouse, near Rotherham, was born in 1593 in Chancery Lane, London He was educated at St John's College, Cambridge, and in 1611 was knighted, and married Margaret, daughter of Francis, earl of Cumberland In 1614 he represented Yorkshire in the Addled Parliament, but, as far as is now known, it was not till the parliament of 1621 that he took part in the debates His position towards the popular party was peculiar He did not sympathize with their eagerness for war with Spain, and he was eager, as no man of that time except Bacon was eager, for increased activity in domestic legislation He was what, in modern times, would be called a reformer, and in those days a reformer was necessarily an upholder of the authority of the crown, in whose service the most experienced statesmen might be expected to be found, whilst the members of a House of Commons only summoned at considerable intervals would be deficient in the qualities necessary for undertaking successful legislation On the other hand, James's conduct of the diplomatic struggle with Spain was not such as to inspire confidence, and Wentworth's bearing was therefore marked by a certain amount of hesitation He was, however, more than most men prone to magnify his office, and James's contemptuous refusal to allow the House of Commons to give an opinion on foreign politics seems to have stung him to join in the vindication of the claims of the House of which he was a member He was at all events a warm supporter of the protestation which drew down a sentence of dissolution upon the third parliament of James

In 1622 Wentworth's wife died, and in February 1625 he married Arabella Holles, the daughter of the earl of Clare Of the parliament of 1624 he had not been a member, but in the first parliament of Charles I he again represented Yorkshire, and at once marked his hostility to the proposed war with Spain by supporting a motion for an adjournment before the House proceeded to business His election was declared void, but he was re-elected When he returned to parliament he took part in the opposition to the demand made under the influence of Buckingham for war subsidies, and was consequently, after the dissolution, made sheriff of Yorkshire, in order to exclude him, as hostile to the court, from the parliament which met in 1626 After the dissolution of that parliament he was dismissed from the justiceship of the peace and the office of *custos rotulorum* of Yorkshire

Wentworth's position was very different from that of the regular opposition He was anxious to serve the crown, but he disapproved of the king's policy "My rule," he wrote December 1625, "which I will never transgress, is never to contend with the prerogative out of parliament, nor yet to contest with a king but when I am constrained thereunto or else make shipwreck of my peace of conscience" In January 1626 he had asked for the presidency of the Council of the North, and had visited and made overtures to Buckingham His subsequent dismissal was probably the result of his resolution not to support the court in its design to force the country to contribute money without a parliamentary grant At all events, he refused in 1627 to contribute to the forced loan, and was placed in confinement in Kent for his refusal

Wentworth's position in the parliament of 1628 was a striking one He joined the popular leaders in resistance to arbitrary taxation and imprisonment, but he tried to obtain his end with the least possible infringement of the prerogative of the crown, to which he looked as a reserve force in times of crisis With the approbation of the House he led the movement for a bill which would have secured the liberties of the subject as completely as the Petition of Right afterwards did, but in a manner less offensive to the king. The proposal was wrecked upon Charles's refusal to make the necessary concessions, and the leadership was thus snatched from Wentworth's hands by Eliot and Coke Later in the session he fell into conflict with Eliot, as, though he supported the Petition of Right in substance, he was anxious to come to a compromise with the Lords, so as to leave room to the king to act unchecked in special emergencies

On July 22, 1628, not long after the prorogation, Wentworth was created Lord Wentworth, and received a promise of the presidentship of the Council of the North at the next vacancy Even on political matters he had never been quite at unison with the parliamentary opposition, and in church matters he was diametrically opposed to them Since the close of the discussion on the Petition of Right, church matters had come into greater prominence

[1] See No 1272 in *Cat Harl MSS*, *Brit Mus* Wanley, however, believed Stradella alone to have been murdered and the lady to have escaped

[2] Called in some editions *Se i miei sospiri*.

than ever, and Wentworth was therefore thrown strongly on the side of Charles, from whom alone opposition to Puritanism could possibly come. This attachment to Charles was doubtless cemented by Buckingham's murder, but, if he took the king's part with decision and vigour, it must be remembered that, as has been already said, he was above all a man prone to magnify his office, and that things would look differently to him than they had done before he was in his new position. For the charge of apostasy in its ordinary meaning there is no foundation.

As yet Wentworth took no part in the general government of the country. In December he became Viscount Wentworth and president of the Council of the North. In the speech delivered at York on his taking office he announced his intention of doing his utmost to bind up the prerogative of the crown and the liberties of the subject in indistinguishable union. "Whoever," he said, "ravels forth into questions the right of a king and of a people shall never be able to wrap them up again into the comeliness and order he found them."

The session of 1629 ended in a breach between the king and the parliament which made the task of a moderator hopeless. Wentworth had to choose between helping a Puritan House of Commons to dominate the king and helping the king to dominate a Puritan House of Commons. He instinctively chose the latter course, and he threw himself into the work of repression with characteristic energy, as if the establishment of the royal power was the one thing needful. Yet even when he was most resolute in crushing resistance he held that he and not his antagonists were maintaining the old constitution which they had attempted to alter by claiming supremacy for parliament.

In November 1629 Wentworth became a privy councillor. In October 1631 he lost his second wife, and in October 1632 he married Elizabeth Rhodes. In January 1632 he had been named lord-deputy of Ireland, having performed his duties at York to the king's satisfaction, though he had given grave offence to the northern gentry by the enforcement of his authority. It was a cardinal point of his system that no wealth or station should exempt its possessor from obedience to the king. Not only was the announcement of this principle likely to give offence to those who were touched by it, but in its application Wentworth was frequently harsh and overbearing. In general he may have been said to have worked rather for equality under a strong Government than for liberty.

In Ireland Wentworth would have to deal with a people which had not arrived at national cohesion, and amongst which had been from time to time introduced English colonists, some of them, like the early Norman settlers, sharing in the Catholicism of the natives, whilst the later importations stood aloof and preserved their Protestantism. There was also a class of officials of English derivation, many of whom failed to reach a high standard of efficiency. Against these Wentworth, who arrived in Dublin in July 1633, waged war sometimes with scanty regard to the forms of justice, as in the case of Lord Mountnorris, whom he sent before a court-martial on a merely formal charge, which necessarily entailed a death sentence, not because he wanted to execute him, but because he knew of no other way of excluding him from official life.

The purifying of official life, however, was but a small part of Wentworth's task. In one way, indeed, he conceived his duty in the best spirit. He tried at the same time to strengthen the crown and to benefit the poor by making the mass of the nation less dependent on their chiefs and lords than they had been before, and, though Wentworth could not do away with the effects of previous mistakes, he might do much to soften down the existing antagonism between the native population and the English Government. Unhappily his intentions were frustrated by causes resulting partly from his own character and partly from the circumstances in which he was placed.

In the first place, Wentworth's want of money to carry on the Government was deplorable. In 1634 he called a parliament at Dublin, and obtained from it a considerable grant, as well as its co-operation in a remarkable series of legislative enactments. The king, however, had previously engaged his word to make certain concessions known as the "graces," and Wentworth resolved that some of these should not be granted, and took upon himself to refuse what his master had promised. The money granted by parliament, however, would not last for ever, and Wentworth resolved to create a balance between revenue and expenditure before the supply was exhausted. This he succeeded in doing, partly by making a vast improvement in the material condition of the country, and partly by the introduction of monopolies and other irregular payments, which created wide dissatisfaction, especially amongst the wealthier class.

Towards the native Irish Wentworth's bearing was benevolent but thoroughly unsympathetic. Having no notion of developing their qualities by a process of natural growth, his only hope for them lay in converting them into Englishmen as soon as possible. They must be made English in their habits, in their laws, and in their religion. "I see plainly," he once wrote, "that, so long as this kingdom continues Popish, they are not a people for the crown of England to be confident of." It is true that he had too much ability to adopt a system of irritating persecution, but from time to time some word or act escaped from him which allowed all who were concerned to know what his real opinion was. For the present, however, he had to content himself with forging the instrument by which the hoped-for conversion was to be effected. The Established Church of Ireland was in a miserable plight, and Wentworth busied himself with rescuing from the hands of such men as the earl of Cork the property of the church, which had in troublous times been diverted from its true purpose, and with enforcing the strict observance of the practices of the English Church, on the one hand upon recalcitrant Puritans, and on the other hand upon lawless disregarders of all decency. In this way he hoped to obtain a church to which the Irish might be expected to rally.

Till that time came, he must rely on force to keep order and to prevent any understanding growing up between the Irish and foreign powers. With this object in view he resolved on pouring English colonists into Connaught as James had poured them into Ulster. To do this he had taken upon himself to set at naught Charles's promise that no colonists should be forced into Connaught, and in 1635 he proceeded to that province, where, raking up an obsolete title, he insisted upon the grand juries in all the counties finding verdicts for the king. One only, that of Galway, resisted, and the confiscation of Galway was effected by the Court of Exchequer, whilst he fined the sheriff £1000 for summoning such a jury, and cited the jurymen to the castle chamber to answer for their offence. He had succeeded in setting all Ireland against him.

High-handed as Wentworth was by nature, his rule in Ireland made him more high-handed than ever. As yet he had never been consulted on English affairs, and it was only in February 1637 that Charles asked his opinion on a proposed interference in the affairs of the Continent. In reply, he assured Charles that it would be unwise to

undertake even naval operations till he had secured absolute power at home. The opinion of the judges had given the king the right to levy ship-money, but, unless his Majesty had "the like power declared to raise a land army, the crown" seemed "to stand upon one leg at home, to be considerable but by halves to foreign princes abroad." The power so gained indeed must be shown to be beneficent by the maintenance of good government, but it ought to exist. A beneficent despotism supported by popular gratitude was now Wentworth's ideal.

In his own case Wentworth had cause to discover that Charles's absolutism was marred by human imperfections. Charles gave ear to courtiers far too often, and frequently wanted to do them a good turn by promoting incompetent persons to Irish offices. To a request from Wentworth to strengthen the position of the deputy by raising him to an earldom he turned a deaf ear. Yet to make Charles more absolute continued to be the dominant note of his policy, and, when the Scottish Puritans rebelled, he advocated the most decided measures of repression, and in February 1639 he offered the king £2000 as his contribution to the expenses of the coming war. He was, however, too clear-sighted to do otherwise than deprecate an invasion of Scotland before the English army was trained.

In September 1639, after Charles's failure in the first Bishops' War, Wentworth arrived in England to conduct in the star-chamber a case in which the Irish chancellor was being prosecuted for resisting the deputy. From that moment he stepped into the place of Charles's principal adviser. Ignorant of the extent to which opposition had developed in England during his absence, he recommended the calling of a parliament to support a renewal of the war, hoping that by the offer of a loan from the privy councillors, to which he himself contributed £20,000, he would place Charles above the necessity of submitting to the new parliament if it should prove restive. In January 1640 he was created earl of Strafford, and in March he went to Ireland to hold a parliament, where the Catholic vote secured a grant of subsidies to be used against the Presbyterian Scots. An Irish army was to be levied to assist in the coming war. When in April Strafford returned to England he found the Commons holding back from a grant of supply, and tried to enlist the peers on the side of resistance. On the other hand, he attempted to induce Charles to be content with a smaller grant than he had originally asked for. The Commons, however, insisted on peace with the Scots, and on May 9, at the privy council, Strafford, though reluctantly, voted for a dissolution.

After this Strafford supported the harshest measures. He urged the king to invade Scotland, and, in meeting the objection that England might resist, he uttered the words which cost him dear, "You have an army in Ireland,"—the army which, in the regular course of affairs, was to have been employed to operate in the west of Scotland,—"you may employ here to reduce this kingdom." He tried to force the citizens of London to lend money. He supported a project for debasing the coinage and for seizing bullion in the Tower, the property of foreign merchants. He also advocated the purchasing a loan from Spain by the offer of a future alliance. He was ultimately appointed to command the English army, but he was seized with illness, and the rout of Newburn made the position hopeless. In the great council at York he showed his hope that if Charles maintained the defensive the country would still rally round him, whilst he proposed, in order to secure Ireland, that the Scots of Ulster should be ruthlessly driven from their homes.

When the Long Parliament met it was preparing to impeach Strafford, when tidings reached its leaders that Strafford, now lord-lieutenant of Ireland, had come to London and had advised the king to take the initiative by accusing his chief opponents of treason. On this the impeachment was hurried on, and the Lords committed Strafford to the Tower. At his trial in Westminster Hall he stood on the ground that each charge against him, even if true, did not amount to treason, whilst Pym urged that, taken as a whole, they showed an intention to change the Government, which in itself was treason. Undoubtedly the project of bringing over the Irish army, probably never seriously entertained, did the prisoner most damage, and when the Lords showed reluctance to condemn him the Commons dropped the impeachment and brought in a bill of attainder. The Lords would probably have refused to pass it if they could have relied on Charles's assurance to relegate Strafford to private life if the bill were rejected. Charles unwisely took part in projects for effecting Strafford's escape and even for raising a military force to accomplish that end. The Lords took alarm and passed the bill. On May 9, 1641, the king, frightened by popular tumults, reluctantly signed a commission for the purpose of giving to it the royal assent, and on the 12th Strafford was executed on Tower Hill. (S. R. G.)

STRAITS SETTLEMENTS, the collective name given to the British possessions in the MALAY PENINSULA (see vol. xv. p. 320, and Plate VI.), derived from the straits which separate the peninsula from Sumatra and which form so important a sea-gate between India and China. The Straits Settlements are defined, by letters patent 17th June 1885, as consisting of the island of Singapore (which contains the seat of government), the town and province of Malacca, the territory and islands of the Dindings (off Perak), the island of Penang, and Province Wellesley, with their dependencies actual or prospective. The Cocos or KEELING ISLANDS (q.v.), formerly attached to Ceylon, were transferred to the Straits Settlements in 1886. These possessions have formed a crown colony since 1867, previous to which they were administered as a presidency of the Indian empire. The governor, appointed for six years, is assisted by an executive and a legislative council. Resident councillors are stationed at Penang and Malacca, and since 1874 British residents have exercised supervision at the native courts of Perak, Selangor, and Sungei Ujong, and are assisted by a staff of European officials.

The following are the area and population (with details of race divisions) of the settlements:—

	Area in sq. miles	Population in 1871	Population in 1881				
			Total	Europeans	Malays	Chinese	Natives of India
Singapore	206	97,131	139,208	2,769	22,155	86,766	12,058
Penang	107	131,889 (Penang and Province Wellesley)	90,951	612	21,772	45,135	15,730
Province Wellesley	270		97,324	76	58,723	21,637	10,616
Malacca	659	77,755	93,579	40	67,513	19,741	1,891
Dindings			2,322				

The population, which thus was 306,775 in 1871 and 423,384 in 1881, was estimated at 473,000 in 1884. The increase is solely produced by immigration of Chinese and natives of India, for, while the total number of births registered in Singapore, Penang, Province Wellesley, and Malacca was in the three years 1881–83 only 21,134, the deaths were 37,151.[1] In 1883 61,206 Chinese landed at Singapore and 48,419 in Penang; and, though the influx of Indian coolies has been retarded by the stringent protective laws of the Indian Government, the stream of immigration has been steadily increasing in volume. The number of Chinese is probably below the truth, as they were very reluctant to fill up the returns. In 1867, the date of the transfer to the crown, the colony had, it was estimated, not more than 283,384 inhabitants.

The revenue, which was in 1868 only about 1,301,843 dollars, had risen by 1886 to 3,710,639, a large proportion being derived

[1] The number of hospital cases, and consequently the death-rate, is affected, however, by the fact that natives from the rest of the peninsula, whose diseases prove beyond native skill, are often brought to the colonial hospitals.

from opium and spirit taxation (712,600 dollars in 1868 and 2,152,700 in 1884). The expenditure in the same period increased from 1,197,177 to 3,652,771 dollars. In 1868 12,400 dollars were credited to education (95,600 in 1884). Public works were credited with 146,800 dollars in 1868 but with 1,170,000 in 1884. The ports of the Straits Settlements are all free. In 1867 the total burden was 1,237,700 tons, in 1873 2,507,000 tons, and in 1883 4,290,600. The value of the united imports and exports was in 1867 about £14,040,000, and in 1883 it was estimated by Sir Frederick Weld at £38,624,200. The imports usually somewhat exceed the exports.

MALACCA.—The territory of Malacca lies between the river Linggi and the Kesang, which separate it respectively from Sungei Ujong to the north-west and the Moar district of Johor to the east. To the north it marches with Negri Sembilan. Forest conservancy is beginning to be carefully attended to, and pepper growing has recently been started with success at Aria Kudah by Achinese settlers. Tapioca and tin are among the exports, the latter, brought from the Selangor mines, being smelted in Malacca. The average birth rate in 1881–83 was 2046 and the death-rate 2642. The city of Malacca has already been described, vol. xv. p. 312.

PRINCE OF WALES ISLAND (or Penang) and SINGAPORE are treated in separate articles.

PROVINCE WELLESLEY, which lies opposite Penang, was at one time part of the Kedah territory, from which it is now separated by the Kwala Muda river. Southwards it extends (since 1874) a little to the south of the Krian river and marches with Perak. The boundary was rectified by treaty with Siam in 1867. Butterworth is the seat of the Government headquarters. The country consists for the most part of fertile plain, and the remainder, about one-eleventh of the whole, is low wooded hills (highest 1843 feet). Some of the low land is rich dark alluvial soil, and much of it is sandy; in the hills a ferruginous sandy loam of rather poor quality prevails. Sugar-growing has long been a staple industry, and tea plantations began to be formed in 1869–70.

THE DINDINGS belonged originally to the state of Perak. The British territory extends some 26 miles from north to south. Though it has a magnificent natural harbour, "it has not hitherto," says Sir Frederick Weld, "been a progressive district. But I think its time is at hand. It produces tin, timber, and ebony, and turtles frequent the neighbouring islands." Dinding Island lies off the mouth of the river of the same name.

PERAK is an extensive tract of country, comprising the great part of the basin of the Perak river (which runs north and south, almost parallel with the coast of the peninsula, for upwards of 130 miles, excluding the windings, before it turns abruptly west to the Strait) and all the basin of the Bernam river. The boundary towards Patani cuts the Perak river at the rapids of Jeram Panjang. The population of the states is about 110,000, among the more noteworthy tribes being the Sakeis. Perak was brought into closer relation to Britain by the treaty signed at Pankor (Pangkore) in the Dindings, 20th January 1874, which authorized the appointment of a British resident and assistant resident. The first resident, J. W. Birch, was murdered in November 1875, but British troops from India and China, under General (Sir Francis) Colborne, soon suppressed the insurrectionary movement. One column crossed from Larut to Kwala Kungsa and defeated the rebels at Kotah Lamah, Enggar, and Prek, and another advanced from Banda Baru (where Mr Birch was buried) to Blanja, the residence of the ex-sultan Ismail, and thence to Kinta on the Kinta river, the capital of Perak. As it was discovered that Abdullah, the ruling sultan, had been accessory to the murder of Mr Birch, he was deposed in 1877 and banished to Mahe (Seychelles). The residency of Lower Perak was removed from Banda Baru to Durian Sabatang, the place where the Bidor and Batang Padang join the main stream of the Kungsa or Perak, and it has again been removed to Teluk Anson (Teluk Mah Intan), lower down, the centre of the inland trade. The residency of Upper Perak is at Kwala Kungsa. Perak has made wonderful advance since the war. Its revenue was 312,875 dollars in 1877, and in 1884, at a moderate estimate, 1,485,697. In 1877 there was only one line of good road in the country,—from Larut through the pass of Bukit Berapit to Kwala Kungsa; now large tracts have been opened up with roads and bridle-paths. "Rivers have been cleared of obstructions, telegraph lines laid down, court-houses, hospitals, police-stations, &c., built, and a line of railway (8 miles) constructed from Port Weld, the port of Larut, at Teluk Kartang, where vessels drawing 13 to 15 feet can enter to Taipeng (Thaipeng)." The revenue is mainly derived from a duty on tin, which is largely mined in Larut, &c. The mines of the Capitan China in 1883 produced to the value of £105,000. Coffee and tea planting seem to promise well.

SELANGOR lies to the south of Perak, and consists mainly of the basins of the Selangor, the Klang, and the Langat, of which the last two meet in a common delta to the south of 3° N. lat. Previous to 1880 the seat of the British resident and staff was at Klang, at the head of 13-feet navigation on the Klang river; at that date it was transferred to Kwala Lumpur, at the junction of the Gombah with the Klang, the highest point reached by the cargo boats which bring up provisions for the tin miners and return with tin, gutta-percha, and other produce. There are tin mining settlements at Kanching, Ulu Selangor, Ulu Bernam, Ulu Gombah, Ulu Klang, Ulu Langat, Sungie Pateh Reeko, Kajang, Ampagnan, &c. The mine at Ampagnan was bought for 170,000 dollars by Singapore merchants. The population of Selangor (50,000,—29,000 of them Chinese) is rapidly increasing by immigration from China, India, and Sumatra. Since the close of the civil war (1867–74) and the acceptance of the British resident the country has rapidly developed. At the mouth of the Selangor lies the town of that name, with ruins of an old Dutch fort and the stone on which the sultans of Selangor receive investiture. At Klang, up the Klang river, lies the principal port of the country, now connected by railway with Kwala Lumpor (22 miles distant), the capital, which has grown into a considerable town, with a hospital, Government house, residency, &c. The sultan resides at Jugra, on a deltaic branch of the Langat. The revenue of Selangor was estimated at 596,877 dollars in 1884, but the war debt was still 259,000 dollars in 1883.

SUNGEI UJONG (500 square miles, including Lukut and Sungei Riah; population 14,000, the greater part being Chinese) also shows steady progress. Its revenue rose from 67,000 dollars in 1874–75 to 121,176 in 1884. European coffee and cocoa plantations and Chinese tapioca, pepper, and gambier plantations are at work.

The interference of the British Government is frequently sought in the territory of the Negri Sembilan (the so-called "Nine States," which are now really seven in number), Sri Menanti, Numbaw, Johole, Jellye, Muar, Jempolt, Segamet.

See *Journal of the Straits Asiatic Society*, Singapore; Dowden, *The Malay Peninsula*, 1882; Vacher, *Twelve Years in Malaya*; M'Nair, *Perak and the Malays*, 1878; W. B. D'Almeida, "Geography of Perak and Salangore," in *J. Roy. Geog. Soc.*, 1876; Sir Frederick Weld, "Straits Settlements," in *Proceedings of Royal Colonial Institute*, 1883–84; *The Straits Directory*, 1886; and the works mentioned in the article MALAY PENINSULA.

STRALSUND, a seaport and small manufacturing town in Western Pomerania, Prussia, is situated on the Strelasund, an arm of the Baltic Sea, 2 miles wide, which separates the island of Rugen from the mainland, 115 miles to the north of Berlin and 85 miles to the north-west of Stettin. The position of the town on a small triangular islet, only connected with the mainland by moles and bridges at the angles, has always rendered its fortification comparatively easy, and down to 1873 it was a fortress of the first rank. The quaint architecture of the houses, many of which present their curious and handsome gables to the street, gives Stralsund an interesting and old-fashioned appearance. The three vast Gothic churches of St Nicholas, St Mary, and St James, erected in the 14th and 15th centuries, and the town-house, dating in its oldest part from 1316, are among the more striking buildings. The public library, founded in 1709, contains 60,000 volumes. The manufactures of Stralsund are more miscellaneous than extensive; they include machinery, beer, oil, paper, playing-cards, and sugar. The trade is chiefly confined to the shipping of grain, malt, and timber, with some cattle and wool. In 1884 542 sea-going ships and 1964 river-craft entered the harbour, which is protected by the fortified island of Danholm, and 513 ships and 1964 river-craft cleared. In 1882 the port owned a fleet of 247 sea-going ships, with a burden of 41,176 tons, besides numerous smaller craft below 60 tons. The population in 1880 was 29,481, in 1885 28,981. More than a fourth of the inhabitants reside in the Knieper, Tribseer, Franken, and Harbour suburbs on the mainland. About 1000 are Roman Catholics and 140 Jews.

Stralsund was founded in 1209 by Jaromar I., prince of Rugen, and, though several times destroyed, steadily prospered. It was one of the five Wendish towns whose alliance extorted from King Eric of Norway a favourable commercial treaty in 1284–85, and in the 14th century it was second only to Lubeck in the Hanseatic League. Although under the sway of the dukes of Pomerania, the city was able to maintain a marked degree of independence, which is still apparent in its municipal privileges, it is also the only town in Prussia, with the exception of Breslau, which has an independent municipal ecclesiastical consistory. Its early Protestant sympathies placed it on the side of Sweden during the Thirty Years' War, and in 1628 it successfully resisted a siege of eleven weeks by Wallenstein, who had sworn to take it "though it were chained to heaven." He was forced to retire with the loss of

12,000 men, and a yearly festival in the town still celebrates the occasion After the peace of Westphalia Stralsund was ceded with the rest of Western Pomerania to Sweden, and for more than a century and a half it was exposed to attack and capture as the *tête de-pont* of the Swedes in Continental Europe In 1815 it passed to Prussia In 1809 it was the scene of the death of Major Schill, in his gallant though ineffectual attempt to rouse his countrymen against the French invaders

STRANGE, SIR ROBERT (1721–1792), an eminent line engraver, was descended from the Scottish family of Strange, or Strang, of Balcasky, Fife, and was born in the Mainland of Orkney, on July 14, 1721 In his youth he spent some time in an attorney's office, but, having manifested a taste for drawing, he was apprenticed, in 1735, to Richard Cooper, an engraver in Edinburgh After leaving Cooper in 1741, he started on his own account as an engraver, and had attained a fair position when, in 1745, he joined the Jacobite army as a member of the corps of life guards He engraved a half-length of the Young Pretender, and also etched plates for a bank-note designed for the payment of the troops He was present at the battle of Culloden, and after the defeat remained in hiding in the Highlands, but ultimately returned to Edinburgh, where, in 1747, he married Isabella, only daughter of William Lumisden, son of a bishop of Edinburgh

In the following year he proceeded to Rouen, and there studied drawing under J B Descamps, carrying off the first prize in the Academy of Design In 1749 he removed to Paris, and placed himself under the celebrated Le Bas It was from this master that he learned the use of the dry point, an instrument which he greatly improved, and employed with excellent effect in his own engravings In 1750 Strange returned to England Presently he settled in London along with his wife and daughter, and superintended the illustrations of Dr William Hunter's great work on the *Gravid Uterus*, published in 1774 The plates were engraved from red chalk drawings by Van Rymsdyk, now preserved in the Hunterian Museum, Glasgow, and two of them were executed with great skill by Strange's own hand By his plates of the Magdalen and Cleopatra, engraved after Guido in 1753, he at once established his professional reputation

He was invited in 1759 to engrave the portraits of the prince of Wales and Lord Bute, by Allan Ramsay, but declined, on the ground of the insufficient remuneration offered and of the pressure of more congenial work after the productions of the Italian masters His refusal was attributed to his Jacobite proclivities, and it led to an acrimonious correspondence with Ramsay, and to the loss, for the time, of royal patronage In 1760 Strange started on a long-meditated tour in Italy He studied in Florence, Naples, Parma, Bologna, and Rome, executing innumerable drawings, of which many—the Day of Correggio, the Danae and the Venus and Adonis of Titian, the St Cecilia of Raphael, and the Barberini Magdalen of Guido, &c —were afterwards reproduced by his burin On the Continent he was received with great distinction, and he was elected a member of the academies of Rome, Florence, Parma, and Paris He left Italy in 1764, and, having engraved in the French capital the Justice and the Meekness of Raphael, from the Vatican, he carried them with him to London in the following year

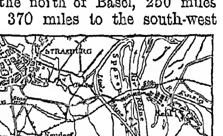
The rest of his life was spent mainly in these two cities, in the diligent prosecution of his art In 1766 he was elected a member of the Incorporated Society of Artists, and in 1775, piqued by the exclusion of engravers from the Royal Academy, he published an attack on that body, entitled *An Enquiry into the Rise and Progress of the Royal Academy of Arts at London*, and prefaced by a long letter to Lord Bute In 1787 he engraved West's Apotheosis of the Princes Octavius and Alfred, and was rewarded with the honour of knighthood He died in London on the 5th of July 1792

In the technique of engraving Strange was a master His line is tender and flowing, without monotony or confusion, and his expression of flesh is characterized by uncommon delicacy and transparency In draftsmanship his works are often defective

After his death a splendid edition of reserved proofs of his engravings was issued, and a catalogue of his works, by Charles Blanc, was published in 1848 by Rudolph Weigel of Leipsic, forming part of *Le Graveur en Taille Douce* See *Memoirs of Sir Robert Strange, Knt, and his Brother-in-law Andrew Lumisden*, by James Dennistoun of Dennistoun, 1855

STRANRAER, a royal burgh of Wigtownshire, Scotland, is situated on the North Channel, at the head of Loch Ryan, 7½ miles north-east of Portpatrick, and 59 miles south-south-west of Ayr In the centre of the town is the old baronial castle of the 15th century occupied by Claverhouse when he held the office of sheriff of Galloway The principal public buildings are the old town-hall, the new town hall and court-house (1873), and the academy (1845) A reformatory provides accommodation for 100 boys, and there is a combination poorhouse for the county and a few parishes beyond it The town possesses a library and public reading-room The harbour, which is tidal, only admits the entrance of vessels of 150 tons, but there is good anchorage in the loch, and the east pier permits of the approach of large steamers, which ply in connexion with the railway daily to Larne in Ireland There is also steam communication with Glasgow, Liverpool, and other towns, but since the construction of the Girvan and Portpatrick Railway the trade of the port has been on the decline The principal import is coal, and the principal exports are agricultural produce The town is chiefly dependent on agriculture The fishing industry is of minor importance The population in 1881 of the royal burgh (area 55 acres) was 3455, and of the police burgh 6342 The town was created a burgh of barony in 1596, and a royal burgh in 1617 In 1885 its parliamentary representation (it had been one of the Wigtown burghs) was merged in that of the county

STRASBURG (Germ *Strassburg*, Fr *Strasbourg*), the principal town of Alsace, and a fortress of the first rank, is situated at the junction of the Ill and the Breusch, about two miles to the west of the Rhine, in one of the most fertile districts in the upper Rhenish plain It lies about 90 miles to the north of Basel, 250 miles to the east of Paris, and 370 miles to the south-west of Berlin Since 1871 it has been the seat of government for the German crownland of Alsace-Lorraine (Elsass-Lothringen), and it is also the see of a Roman Catholic bishop and the headquarters of the 15th corps of the German army



Environs of Strasburg

The town proper is divided by the arms of the Ill into three parts, of which the central is the largest and most important Most of the streets are narrow and irregular, and the quaint aspect of a free mediæval town has to a considerable extent been maintained The quarters which suffered most in the bombardment of 1870 have, however, been rebuilt in a more modern fashion, and the recent widening of the circle of fortifications, with the destruction of the old walls, has given the city opportunity to expand in all directions

By far the most prominent building is the minster, or cathedral, which in its present form represents the activity of four centuries Part of the crypt dates from about 1015, the apse shows the transition from the Romanesque to the Gothic style, and the nave, finished

in 1275, is a fine specimen of pure Gothic Of the elaborate west façade, with its singular screen of double tracery, the original design was furnished by Erwin of Steinbach (*c* 1318) The upper part of the façade and the towers were afterwards completed in accordance with a different plan, and the intricate open-work spire on the north tower, 465 feet high, was added in 1435 The sculptural ornamentation both without and within is very rich The astronomical clock in the south transept, constructed in 1838–42, contains some fragments of the famous clock built by Dasypodius in 1571 The church of St Thomas, a Gothic building of the 13th and 14th centuries, contains a fine monument to Marshal Saxe, considered the *chef d'œuvre* of the sculptor Pigalle Other notable buildings are the Temple-Neuf, or Neukirche, rebuilt since 1870, the old episcopal palace (1731–41), now the library, the old prefecture, the theatre, the town-house, and the so-called "aubette," containing the conservatorium of music The university of Strasburg, which was suppressed in the French Revolution as a stronghold of German sentiment, was reopened in 1872, and now occupies

a handsome new building erected for it in 1884 The university and town library, containing about 600,000 volumes, consists largely of the books sent from all parts of Germany to compensate for the town library destroyed in the bombardment of 1870 The precious incunabula and manuscripts which then perished are, however, irreplaceable General Kleber, who was a native of Strasburg, and Gutenberg, who spent part of his life here, are both commemorated by statues Many private houses are most quaint and interesting illustrations of timber architecture Pleasant public parks and gardens fringe the town

The population in 1880 was 104,471, including 51,859 Roman Catholics, 48,691 Protestants, and 3521 Jews In 1885 the total population had risen to 112,091, showing an increase of 7 29 per cent The town, strictly so called, does not contain more than 90,000 inhabitants, the rest belonging to the suburban villages Even before the war of 1870–71 more than half of the inhabitants spoke German as their mother-tongue, and this proportion has probably been somewhat increased since The sympathies of the people, however, like those of most of the Alsatians, lay with France, and it will require the growth of a new generation to bring about a complete reconciliation to German rule

The chief industries of Strasburg are tanning, brewing, and the making of steel goods, machinery, and tobacco To these must be added the stall-fattening of geese for its celebrated *pâtes de foie gras*, an occupation which forms a most useful source of income to the poorer classes The annual value of these "fat liver pies" sent out from Strasburg is over £100,000 The position of the town at the intersection of natural highways between France and Germany, Switzerland and Belgium, early made it a place of considerable commercial importance, and it now carries on a brisk trade in agricultural produce, hams, sausages, sauerkraut, and hops Its full development in this direction, though favoured by the canals connecting the Rhine with the Rhone and the Marne, has been somewhat hampered by the iron girdle of fortifications

Strasburg has always been a place of great strategic importance, and as such strongly fortified The pentagonal citadel constructed by Vauban in 1682–84 was destroyed during the siege of 1870 The new German system of fortifications consists of a girdle of fourteen detached forts, at a distance of three to five miles from the centre of the town Kehl, the *tête-de-pont* of Strasburg, and several villages are included within this enceinte, and three of the outworks lie on the right bank of the Rhine, in the territory of Baden In case of need a great part of the environs can be laid under water by the garrison.

The site of Strasburg seems to have been originally occupied by a Celtic settlement, which the Romans conquered and replaced by the fortified station of *Argentoratum*, afterwards the headquarters of the eighth legion In the year 357 the emperor Julian saved the frontier of the Rhine by a decisive victory gained here over the Alemanni, but about half a century later the whole of the district now called Alsace fell into the hands of that Teutonic people Towards the end of the 5th century the town passed to the Franks, who named it *Strataburgum* The famous "Strasburg oaths" (see GERMANY, vol x p 480) were taken here in 842, and in 923, through the homage paid by the duke of Lorraine to Henry I, began the connexion of the town with the kingdom of Germany which was to last for more than seven centuries The bishopric of Strasburg was founded in the Merovingian period, and soon attained great wealth and importance The early history of Strasburg, as in the case of most episcopal cities, consists mainly of a record of the struggle between the bishops and the citizens,—the latter, as they grew in wealth and power, feeling the fetters of ecclesiastical rule inconsistent with their full development The conflict was finally decided in favour of the citizens by the battle of Oberhausbergen in 1262, and the position of free imperial city, which had been conferred upon Strasburg by Philip of Swabia, was not again disputed The throwing off of the episcopal yoke was followed by an internal revolution (1332), which admitted the guilds to a share in the government of the city and impressed upon it the democratic character that it bore down to the French Revolution Strasburg now became one of the most flourishing of all the imperial towns, and the names of natives or residents like Sebastian Brant, Tauler, Fischart, and Geiler von Kaysersberg show that its pre-eminence was not confined to the material sphere On the other hand, its fair fame is sullied by such acts as the burning in 1349 of 2000 Jews, accused of causing a pestilence by poisoning the wells In 1381 Strasburg joined the Stadtebund, or Swabian League, and about a century later it rendered efficient aid to the Swiss confederates at Granson and Nancy The Reformation found ready acceptance at Strasburg, its foremost champion here being Martin Bucer, and the city was skilfully piloted through the ensuing period of religious dissension by its "stadtmeister" Jacob Sturm, who secured for it very favourable terms at the end of the Schmalkald War In the Thirty Years' War Strasburg escaped without molestation by observing a prudent neutrality In 1681, during a time of peace, it was suddenly seized by Louis XIV, and this unjustifiable action received formal recognition at the peace of Ryswick in 1697 The immediate effect of the change of superiors was a partial reaction in favour of Roman Catholicism, but the city remained essentially German until the French Revolution, when it was deprived of its privileges as a free town and sank to the level of a French provincial capital It was at Strasburg that Louis Napoleon made his first ineffectual attempt to grasp power In the war of 1870 Strasburg, with its garrison of 17,000 men, surrendered to the Germans after a siege of seven weeks The town and cathedral suffered considerably from the bombardment, but all traces of the havoc have now disappeared

STRASS, or PASTE See GLASS, vol x p 665.

STRATEGY See WAR

STRATFORD, usually designated STRATFORD-ON-AVON, a market-town and municipal borough of England, in Warwickshire, near the Gloucestershire border, is pleasantly situated on the Avon, and on the Great Western and Midland Railway lines, 26 miles south of Birmingham and 8 south-west of Warwick The Avon is crossed by a stone bridge of fourteen arches, built by Sir Hugh Clopton in the

reign of Henry VII, and widened in 1814, by a bridge of nine arches, built of brick in 1826, and by a foot-bridge erected in 1867, at a cost of £500, on the site of a foot-bridge originally erected in 1599, and rebuilt in 1812. The streets are wide and regular, crossing each other generally at right angles, and, says J. O. Halliwell-Phillipps, "with the exception of a few diffused buildings, scarcely one of which is in its original condition, there is no resemblance between the present town and the Shakespearean borough" (compare article SHAKESPEARE, vol. xxi. pp. 741 *sq.*). The church of the Holy Trinity occupies the site of a Saxon monastery, which existed before 691, when the bishop of Worcester received it in exchange from Ethelred, king of Mercia. It is a fine cruciform structure, partly Early English and partly Perpendicular, with a central tower and lofty octagonal spire. It was greatly improved in the reign of Edward III. by John de Stratford, who rebuilt the south aisle. He also in 1332 founded a chantry for priests, and in 1351 Ralph de Stratford built for John's chantry priests "a house of square stone," which came to be known as the college, and in connexion with which the church became collegiate. The present beautiful choir was built by Dean Balshall (1465-91), and in the reign of Henry VII. the north and south transepts were erected. The mural monument of Shakespeare, who is buried in the chancel, is of special interest from its effigy of the poet, undoubtedly an authentic representation, though somewhat altered and damaged by time. The foundation of the chapel of the guild of the Holy Cross was laid by Robert de Stratford. The guild, to which both sexes were admitted, was in existence early in the 13th century, and it was incorporated by a charter from Edward III. in 1322. It was dissolved in 1547. The house in which Shakespeare was born still stands,—although its external appearance is much altered,—and an apartment is by immemorial tradition pointed out as his birth-room. In 1597 Shakespeare purchased New Place for his residence (see vol. xxi. p. 765). Shakespeare's house was pulled down by Sir John Clopton in 1702, and the large new mansion erected on its site was pulled down by Sir Francis Gastrell in 1759. Chiefly through the exertions of J. O. Halliwell-Phillipps, the site of New Place was purchased by public subscription, and in 1876 handed over to the trustees of the birthplace. The old theatre, which had occupied part of the ground, was taken down in 1872, and in 1877 a new memorial theatre was erected at a cost of £30,000. The other principal buildings of the town are the town-hall, originally erected in 1633, almost entirely rebuilt in 1767-68, after having been severely injured by an explosion, and greatly altered in 1863 at a cost of £2000, the market-house (1820), the corn exchange (1850), the children's hospital (1871), and the new hospital (1884). The Edward VI. grammar school, where Shakespeare received his education, was founded in 1553. The town is chiefly dependent on the agriculture of the neighbourhood. The population of the borough in 1871 was 7183, and in 1881 (area extended in 1879 to 3865 acres) it was 8054.

There is no authentic mention of Stratford earlier than the 7th century. It received a charter for a market in the reign of Richard I., but was not incorporated till the reign of Edward VI. The charter of Charles II., granted in his 26th year, remained the governing charter of the town till the passing of the Municipal Act in 1835. The town suffered from a severe epidemic in 1564, from inundations in 1588, and from fire in 1598.

See S. L. Lee, *Stratford on Avon*, 1884; J. O. Halliwell Phillipps, *Outlines of the Life of Shakspeare*, sixth edition (with a history of New Place), 1886; and the article SHAKESPEARE.

STRATFORD, a town of Canada, capital of Perth county, Ontario, lies on the river Avon (a tributary of the Thames which discharges into Lake St Clair), about 45 miles by rail south-east of Goderich, at the junction of the Goderich and Buffalo division with the main line of the Grand Trunk Railway. In 1849 it was a village of only 200 inhabitants, but between 1871 and 1881 its population rose from 4313 to 8239. It has a town-hall, extensive repairing shops, and several manufactures.

STRATFORD DE REDCLIFFE, STRATFORD CANNING, VISCOUNT (1786-1880), diplomatist, was the first cousin of George Canning the statesman, and the youngest son of Stratford Canning, who, having been disinherited for marrying beneath his rank, settled in London as a merchant in Clement's Lane, where young Canning was born 4th November 1786. Shortly afterwards the father died, and the family removed to Wanstead, the boy attending the village school and afterwards a school at Hackney until 1794, when he went to Eton. Ultimately he became captain of the school, and he also manifested his literary predilections by publishing, in conjunction with Wellesley and others, a collection of essays entitled *The Miniature*. In 1805 he was elected scholar of King's College, Cambridge, and, while still attending the university, became in 1807 précis writer to his cousin, who had been appointed foreign minister. At the close of the year he went to Copenhagen as one of the secretaries of a special diplomatic mission, and after his return he was appointed in June 1808 first secretary at Constantinople. On the removal of his chief Mr Adair to Vienna in July 1810, Canning remained minister plenipotentiary, making use of the opportunity to give indications of that over-mastering purpose and bold yet subtle diplomacy which were to have such an important influence on the history of the Eastern question. In 1812 he succeeded in effecting the treaty of Bucharest between Russia and Turkey, which was signed on the 12th May, shortly before the arrival of his successor. This was properly the inauguration of that English influence in Turkey which did not cease until within recent years. The treaty was also of immense immediate advantage by freeing the Russian army to act against Napoleon, and on his return to England Canning was rewarded by a pension of £1200 a year. He remained in London, occupying himself with literature, and contributing some articles to the *Quarterly Review*, then newly founded, until in May 1814 he was appointed by Lord Castlereagh minister plenipotentiary to Switzerland, where he succeeded in effecting the federation of the cantons as a neutral state. He returned to England in 1817, and in August 1820 was sent as plenipotentiary to the United States, to arrange certain outstanding differences between the States and England; but, although a convention was signed 13th March 1824, this was rejected by the American senate, and matters for several years remained, so far as any actual arrangement was concerned, *in statu quo*. In October 1825 Canning was sent on a second commission to Constantinople, chiefly to promote the independence of Greece, but after long and complicated negotiations the attack, without the knowledge of the ambassadors, on the Turkish fleet by the allies under Sir E. Codrington at Navarino, 20th October 1827, caused a conference then being held to be suddenly broken up, and rendered necessary the withdrawal of the ambassadors from Constantinople. They, however, again met at Poros towards the close of the following year, and ultimately Turkey was compelled, by the treaty of Adrianople, 14th August 1829, following a short war with Russia, to loose her grasp on Greece, and consent to the arrangement of a frontier limit. On his return to England Canning was made G.C.B. In 1828 he had been elected to the House of Commons for Old Sarum, and he sat for different boroughs until 1841, when he again accepted the office of ambassador to Turkey. During the next twelve years he gradually succeeded in winning the confidence of the sultan, as well as awakening his wholesome awe, by convincing him, not

merely of his sincere interest in the welfare of Turkey, but of his sole ability to thwart the wiles of the Russian emperor There is no doubt a certain degree of exaggeration in Kinglake's description of Canning as the "Great Elchi," at whose slightest frown the Turks were ready to quail, and by whose matchless skill and coolness the emperor Nicholas was placed at his wits' end, but the consummate ability with which he managed the negotiations connected with the question of the Holy Places, so as to place the emperor as much as possible in the wrong, and to render his act of hostility on 3d July 1853—which led to the Crimean war—unjustifiable, cannot be denied During the war he retained his position at Constantinople, but at its conclusion he returned in 1858 to London In 1852 he had been raised to the peerage with the title Viscount Stratford de Redcliffe His later years were spent chiefly in retirement, and, except when the Eastern question came prominently into notice, he took little part in political discussion On Eastern politics he contributed several papers to the *Times* and the *Nineteenth Century* He died without surviving male issue 14th August 1880

His essays were collected and published in 1881 under the title of the *Eastern Question*, with a memorial preface by Dean Stanley A memoir by Stanley Lane Poole is in preparation

STRATO See PERIPATETICS, vol XVIII. p 545

STRAUBING, an ancient town in the most fertile part of Lower Bavaria, is situated on the right bank of the Danube, 25 miles to the south-east of Ratisbon Its oldest and most characteristic building is the tall square tower of the town-hall, with its five pointed turrets, dating from 1208 The church of St James is a good Late Gothic edifice (1292–1512), with some paintings ascribed to Wohlgemuth, and the old Carmelite church contains a handsome monument to Duke Albert II of Bavaria The industries of Straubing are tanning, brewing, and trade in grain and cattle The population in 1880 was 12,625, nearly all Roman Catholics

Straubing is a town of remote origin, believed to be identical with the Roman station of *Servioduram* In definite history, however, it is known only as a Bavarian town, and from 1333 to 1425 it was the seat of the collateral ducal line of Baiern-Straubing Its chief historical interest attaches to its connexion with the unfortunate Agnes Bernauer, who lived at the chateau here with her husband Duke Albert III During the latter's absence his father, Duke Ernest, exasperated at the mesalliance, cruelly and unjustly condemned his son's low-born wife to death, and caused her to be hurled into the Danube from the bridge (1435) A chapel in the churchyard of St Peter's is said to cover her remains Fraunhofer the optician was born at Straubing in 1787

STRAUSS, DAVID FRIEDRICH (1808–1874), author of the *Leben Jesu*, was born at Ludwigsburg, near Stuttgart, January 27, 1808 He was the son of a small tradesman who loved literature and thought more than business, and his mother was a bright intelligent woman whose piety was practical rather than meditative, while she had an open eye for the beauties of art and nature In his thirteenth year the boy was sent to the evangelical seminary at Blaubeuren, near Ulm, to be prepared for the study of theology Amongst his school-fellows were youths destined to become equally distinguished with himself, of whom he has given sketches in his *Christian Marklin* Amongst the principal masters in the school were Professors Kern and F C Baur, who infused into their pupils above all a deep love of the ancient classics In 1825 Strauss passed from school to the university of Tubingen The course of study was two years of philosophy and history and three of theology The professors of philosophy failed to interest him, and he accordingly followed pretty much his own devices in this field, devoting himself especially to Schelling, the writers of the romantic school, Jacob Bohme, and even to somnambulistic and other modern superstitions In 1826 his previous teachers, Kern and Baur, removed to Tubingen, and the latter introduced him to the writings of Schleiermacher, which awoke his keen dialectical faculty and delivered him from the vagueness and exaggerations of romantic and somnambulistic mysticism, while for a time he found satisfaction for his religious nature in Schleiermacher's idea of religion In the last year of his stay at Tubingen he read with Marklin Hegel's *Phanomenologie*, which was the beginning of his abandonment of Schleiermacher for Hegel. In 1830 he passed his examination brilliantly, and became assistant to a country clergyman, and was greatly beloved as preacher and pastor by the parishioners After nine months in this position he accepted the post of professor in the high school at Maulbronn, having to teach Latin, history, and Hebrew Here also he was most successful and highly valued But in October 1831 he resigned his office in order to study under Schleiermacher and Hegel in Berlin Hegel died just as he arrived, and, though he regularly attended Schleiermacher's lectures, it was only those on the life of Jesus which exercised a very powerful influence upon him It was amongst the followers of Hegel that he found kindred spirits Under the leading of Hegel's distinction between "Vorstellung" and "Begriff," he had already conceived the idea of his two principal theological works—the *Life of Jesus* and the *Christian Dogmatics* In 1832 he returned to Tubingen and became repetent in the university, lecturing on logic, history of philosophy, Plato, and history of ethics, with great success But in the autumn of 1833 he resigned this position in order to devote all his time to the completion of his projected *Life of Jesus* In a year the manuscript was finished, and in 1834 the first volume and in 1835 the second were given to the world The work produced an immense sensation and created a new epoch in the treatment of the rise of Christianity The chief replies to it were by Tholuck, Neander, A Schweizer, Ullmann, and Bruno Bauer In 1837 Strauss replied to his critics (*Streitschriften zur Vertheidigung meiner Schrift uber das Leben Jesu*) In the third edition of the work (1839), and in *Zwei friedliche Blatter*, he made important concessions to his critics, which he withdrew, however, in the fourth edition (1840, translated into English by George Eliot, with Latin preface by Strauss, 1846) In 1840 and the following year he published his *Christliche Glaubenslehre* (2 vols), the principle of which is that the history of Christian doctrines is their disintegration Between the publication of this work and that of the *Friedliche Blatter* he had been elected to a chair of theology in the university of Zurich But the appointment provoked such a storm of popular ill-will in the canton that the authorities considered it wise to pension him before he entered upon his duties, although this concession came too late to save the Government With his *Glaubenslehre* he took leave of theology for upwards of twenty years In August 1842 he married Agnes Schebest, a cultivated and beautiful opera singer of high repute, but not adapted to be the wife of a scholar and literary man like Strauss Five years afterwards, when two children had been born, a separation by arrangement was made Strauss resumed his literary activity by the publication of *Der Romantiker auf dem Throne der Cæsaren*, in which he drew a satirical parallel between Julian the Apostate and Frederick William IV of Prussia (1847) In 1848 he was nominated as member of the Frankfort parliament, but was defeated He was elected for the Wurtemberg chamber, but his action was so conservative that his constituents requested him to resign his seat He forgot his political disappointments in the production of a series of biographical works, which secured for him a permanent place in German literature (*Schubart's Leben*, 2 vols, 1849, *Christian Marklin*, 1851, *Frischlin*,

1855, *Ulrich von Hutten*, 3 vols, 1858–60, 4th ed, 1878, *H S Reimarus*, 1862) With this last-named work (see REIMARUS) he returned to theology, and two years afterwards (1864) published his *Leben Jesu fur das Deutsche Volk* (4th ed, 1877) It failed to produce an effect comparable with that of the first *Life*, but the replies to it were many, and Strauss answered them in his pamphlet *Die Halben und die Ganzen* (1865), directed specially against Schenkel and Hengstenberg His *Christus des Glaubens und der Jesus der Geschichte* (1865) is a severe criticism of Schleiermacher's lectures on the life of Jesus, which were then first published From 1865 to 1872 Strauss resided in Darmstadt, where he made the personal acquaintance of the princess Alice and the crown-princess of Germany, receiving from both ladies many marks of esteem In 1870 he published his lectures on *Voltaire* (3d ed, 1872), which were written for the princess Alice and delivered before her In the works of these years it seemed that the truth of Christianity had become still more problematic to Strauss, and this was more obvious than ever in his next and last important work, his confession, and final summary answer to the four great questions—Are we Christians? Have we still religion? What is our conception of the world? How are we to regulate our lives? (*Der Alte und der Neue Glaube*, 1872, 11th ed, 1881, English translation by M Blind, 1873) The work produced a greater sensation than his first *Life of Jesus*, and not least amongst Strauss's own friends, who wondered at his one sided view of Christianity, his professed abandonment of all spiritual philosophy, the strange inconsistencies of his thought, his scientific credulity, and the offensive form of his negations To the fourth edition of the book he added a *Nachwort als Vorwort* (1873) The same year symptoms of a fatal malady appeared, and death followed February 7, 1874 Though his last book renounced in almost frivolous language the hope of immortality, he read Plato's *Phædo* in the Greek during his last days, and Zeller says "his friends bade him adieu with feelings such as Plato has described at the end of that dialogue"

Strauss's mind was almost exclusively analytical and critical, without depth of religious feeling, or philosophical penetration, or historical sympathy His work was accordingly rarely constructive, and, save when he was dealing with a kindred spirit, he failed as an historian, biographer, and critic, strikingly illustrating Goethe's profoundly true principle that loving sympathy is essential for productive criticism His first *Life of Jesus* was directed against not only the traditional orthodox view of the Gospel narratives, but likewise the rationalistic treatment of them, whether after the manner of Reimarus or that of Paulus The mythical theory that the Christ of the Gospels, excepting the most meagre outline of personal history, was the unintentional creation of the early Christian Messianic expectation he applied with merciless rigour and mechanical inconsideration to the narratives But his operations were based upon fatal defects, positive and negative He held a narrow theory as to the miraculous, a still narrower as to the relation of the divine to the human, and he had no true idea of the nature of historical tradition, while, as C F Baur complained, his critique of the Gospel history had not been preceded by the essential preliminary critique of the Gospels themselves With a broader and deeper philosophy of religion, juster canons of historical criticism, with a more exact knowledge of the date and origin of the Gospels, his rigorous application of the mythical theory with its destructive results would have been impossible In his second *Life of Jesus*, though conceding something to C F Baur, he adheres substantially to his mythical theory, while he seeks to make good one defect of the first *Life* by supplying a previous examination of the Gospels But this examination shows little independent research, being scarcely more than the adoption of the conclusions of C F Baur and his earlier disciples. Another advance on the first work is the addition of a sketch of the historical facts of the life of Jesus and of his religious character, but he adheres to his early limited and shallow view of the relation of the divine and the human, and still fails to apprehend the true mission of the founder of the Christian religion But the estimate of the religious mission of Jesus, and of the historical trustworthiness of the Gospels, is far higher in this *Life* than the final one in *Der Alte und der Neue Glaube* As in his philosophical development he exhibited wavering uncertainty, so it is impossible to reconcile his views of Christ and Christianity at different periods of his life Some of the expressions of his last book in this respect are in glaring contrast with the positions he maintained in earlier years

Strauss's works are published in a collected edition in 12 vols, by Zeller, Bonn, 1876–78, without his *Christliche Dogmatik* On his life and works see Zeller's *David Friedrich Strauss in seinem Leben und seinen Schriften*, Bonn, 1874, A Hausrath's *D F Strauss und die Theologie seiner Zeit*, 2 vols, Heidelberg, 1876–78, his own essay on *Julius Kerner*, F J Vischer's *Kritische Gange*, i 3 Karl Schwarz, *Zur Geschichte der neuesten Theologie*, 4th ed, 1869, Heinrich Lang, *Religiose Reden*, vol ii, Dorner, *Geschichte der protestantischen Theologie*, 1876, Nippold, *Handbuch der neuesten Kirchengeschichte*, 1868, J H Scholten, 'Strauss and Christianity,' in *Theological Review*, 1874, Jan and April; Hase, *Geschichte Jesu*, 1876, give critiques from different points of view of Strauss's theological works, particularly his Lives of Jesus (J F S)

STRAUSS, JOHANN (1804–1849), orchestral conductor and composer of dance-music, was born at Vienna, March 14, 1804 In 1819 he obtained his first engagement as a violinist in a small band then playing at the Sperl, in the Leopoldstadt Shortly afterwards he joined Lanner, with whom he remained associated as deputy-conductor until 1825, when he organized a little band of fourteen performers on his own account It was during the carnival of 1826 that Strauss inaugurated his long line of triumphs by introducing his band to the public of Vienna at the Schwan, in the Rossau suburb, where his famous *Taubenl-Walzer* (op 1) at once established his reputation as the best composer of dance-music then living Upon the strength of this success he was invited back to the Sperl, where he accepted an engagement, with an increased orchestra, for six years. Soon after this he was appointed kapellmeister to the 1st Burger regiment, and entrusted with the duty of providing the music for the court balls, while the number of his private engagements was so great that he found it necessary to enlarge his band from time to time until it consisted of more than two hundred performers In 1833 he began a long and extended series of tours throughout northern Europe, eventually visiting England in 1838 In Paris he associated himself with Musard, whose quadrilles became not much less popular than his own waltzes, but his greatest successes were achieved in London, where he arrived in time for the coronation of Queen Victoria, and played at seventy-two public concerts, besides innumerable balls and other private entertainments The fatigue of these long journeys seriously injured Strauss's health, but he soon resumed his duties at the Sperl, and on May 5, 1840 he removed with his band to the Imperial "Volksgarten," which thenceforth became the scene of his most memorable successes Those who enjoyed the privilege of hearing him conduct there could never forget the wonderful delicacy of the performance, over which the master presided with a quiet power which ensured the perfection of every minutest *nuance* In 1844 Strauss began another extensive series of tours In 1849 he revisited London, and, after his farewell concert, was escorted down the Thames by a squadron of boats, in one of which a band played tunes in his honour This was his last public triumph On his return to Vienna he was attacked with scarlet fever, of which he died, September 25, 1849.

Strauss was survived by three sons,—Johann (born 1825), Joseph (1827–1870), and Edward (born 1835), all of whom have distinguished themselves as composers of dance music, and assisted in recruiting the ranks and perpetuating the traditions of the still famous band

STRAUSS-DURCKHEIM, HERCULE (b 1790, d 1865), an eminent French entomologist, was the author of anatomical works of exquisite precision and fulness of detail Two of these (his monographs of the anatomy of the cockchafer and of the cat) are permanent classics, of which the influence has aided greatly in raising the standard of zoological works

STRAWBERRY (*Fragaria*) Apart from its interest as a dessert fruit (see HORTICULTURE, vol xii. p 276), the strawberry has claims to attention by reason of the pecu-

liarities of its structure and the excellent illustrations it offers of the inherent power of variation possessed by the plant and of the success of the gardener in availing himself of this tendency. The genus *Fragaria* consists of a small number (three to four, according to Hooker) of species, native of the temperate regions of both hemispheres, as well as of mountain districts in warmer climes. The tufted character of the plant, and its habit of sending out long slender branches (runners) which produce a new bud at the extremity, are well known. The leaves are usually palmately three-parted, but the number of leaflets may be increased to five or reduced to one. While the flower has the typical Rosaceous structure, the so-called fruit is very peculiar, but it may be understood by the contrast it presents with the "hip" of the rose. In the last-named plant the top of the flower-stalk expands as it grows into a vase-shaped cavity, the "hip," within which are concealed the true fruits or seed-vessels. In the rose the extremity of the floral axis is concave and bears the carpels in its interior. In the strawberry the floral axis, instead of becoming concave, swells out into a fleshy, dome-shaped or flattened mass in which the carpels or true fruits, commonly called pips or seeds, are more or less imbedded but never wholly concealed. A ripe strawberry in fact may be aptly compared to the "fruit" of a rose turned inside out.

The common wild strawberry of Great Britain, which indeed is found throughout Europe and great part of North America, is *F. vesca*, and this was the first species brought under cultivation in the early part of the 17th century. Later on other species were introduced, such as *F. elatior*, a European species, the parent stock of the hautbois strawberries, and especially *F. virginiana* from the United States and *F. chiloensis* from Chiloe. From these species, crossed and recrossed in various manners, have sprung the vast number of different varieties now enumerated in catalogues, whose characteristics are so inextricably blended that the attempt to trace their exact parentage or to follow out their lineage has become impossible. It must suffice to say that the varieties at present cultivated vary in the most remarkable degree in size, colour, flavour, shape, degree of fertility, season of ripening, liability to disease, and constitution of plant. Some, as previously stated, vary in foliage, others produce no runners, and some vary materially in the relative development of their sexual organs, for, while in most cases the flowers are in appearance hermaphrodite, at least in structure, there is a very general tendency towards a separation of the sexes, so that the flowers are males or females only as to function, even although they may be perfect in construction. This tendency to diœcism is a common characteristic among *Rosaceæ*, and sometimes proves a source of disappointment to the cultivator, who finds his plants barren where he had hoped to gather a crop. This happens in the United States more frequently than in Britain, but when recognized can readily be obviated by planting male varieties in the vicinity of the barren kinds. Darwin, in alluding to the vast amount of variability in the so-called "fruit,"—a change effected by the art of the horticulturist in less than three centuries,—contrasts with this variability the fixity and permanence of character presented by the true fruits, or pips, which are distributed over the surface of the swollen axis. The will and art of the gardener have been directed to the improvement of the one organ, while he has devoted no attention to the other, which consequently remains in the same condition as in the wild plant. Too much stress is not, however, to be laid on this point, for it must be remembered that the foliage, which is not specially an object of the gardener's "selection," nevertheless varies considerably.

STRAW MANUFACTURES. Straw forms the raw material of some not unimportant industries. It serves for the thatching of roofs, for a paper-making material, for ornamenting small surfaces as a "straw mosaic," for plaiting into door and table mats, mattresses, &c., and for weaving and plaiting into light baskets, artificial flowers, &c. These applications, however, are insignificant in comparison with the place occupied by straw as a raw material for the straw bonnets and hats worn by both sexes. Of the various materials which go to the fabrication of plaited head-gear the most important is wheaten straw. It is only in certain areas that straw suitable for making plaits is produced. The straw must have a certain length of "pipe" between the knots, must possess a clear delicate golden colour, and must not be brittle. The most valuable straw for plaits is grown in Tuscany, and from it the well-known Tuscan plaits and Leghorn hats are made. The straw of Tuscany, specially grown for plaiting, is distinguished into three qualities,—*Pontederas Semone* being the finest, *Mazzuolo* the second quality, from which the bulk of the plaits are made, while from the third quality, *Santa Fioro*, only "Tuscan pedals" and braids are plaited. The wheat-seed for these straws is sown very thickly on comparatively elevated and arid land, and it sends up long attenuated stalks. When the grain in the ear is about half developed the straw is pulled up by the roots, dried in the sun, and subsequently spread out for several successive days to be bleached under the influence of alternate sunlight and night-dews. The pipe of the upper joint alone is selected for plaiting, the remainder of the straw being used for other purposes. These pipes are made up in small bundles, bleached in sulphur fumes in a closed chest, assorted into sizes, and so prepared for the plaiters. Straw plaiting is a domestic industry among the women and young children of Tuscany and some parts of Emilia. Tuscan plaits and hats vary enormously in quality and value, the plait of a hat of good quality may represent the work of four or five days, while hats of the highest quality may each occupy six to nine months in making. The finest work is excessively trying to the eyes of the plaiters, who can at most give to it two or three hours' labour daily. The exports of plaits and manufactured hats from Leghorn average in value £480,000 annually, about one half of the goods going to America.

The districts around Luton in Bedfordshire and the neighbouring counties have, since the beginning of the 17th century, been the British home of the straw-plait industry. The straw of certain varieties of wheat cultivated in that region is, in favourable seasons, possessed of a fine bright colour and due tenacity and strength. The straw is cut as in ordinary harvesting, but is allowed to dry in the sun before binding. Subsequently straws are selected from the sheaves, and of these the pipes of the two upper joints are taken for plaiting. The pipes are assorted into sizes by passing them through graduated openings in a grilled wire frame, and those of good colour are bleached by the fumes of sulphur. Spotted and discoloured straws are dyed either in pipe or in plait. The plaiters work up the material in a damp state, either into whole straw or split straw plaits. Split straws are prepared with the aid of a small instrument having a projecting point which enters the straw pipe, and from which radiate the number of knife-edged cutters into which the straw is to be split. The plaiting of straw in the Luton district formerly gave employment to many thousands of women and young children, but now vast quantities of plaits are imported at a very cheap rate from Canton in China. The result is that, while the Luton trade is extending, the number of persons it there gives occupation is greatly diminished. In 1871 about 50,000 persons

were employed in the straw industry, and in 1881 the number was only about 31,000 The plaits are sewed partly by hand and in a special sewing-machine, and the hats or bonnets are finished by stiffening with gelatin size, and blocking into shape with the aid of heat and powerful pressure, according to the dictates of fashion The annual output of the straw-plait industry in England is estimated to amount in value to about £4,000,000

In the United States straw-plait work is principally centred in the State of Massachusetts

Many substances besides straw are worked into plaits and braids for bonnets Among these may be noticed thin strips of willow and cane, and the fronds of numerous palms "Brazilian" hats made from the fronds of the palmetto palms, *Sabal Palmetto* and *S mexicana*, are now largely made at St Albans The famous Panama hats, fine qualities of which at one time were worth £20 to £30 each, are made from the leaves of the screw pine, *Carludovica palmata* They are now manufactured at Dresden, Strasburg, and Nancy, and can be purchased at 30s or £2

STREET, George Edmund (1824–1881), one of the ablest architects of the present century, was born at Woodford in Essex in 1824 He obtained his architectural education in the office of Mr Owen Carter at Winchester, and afterwards worked for five years as an "improver" with Sir G G Scott in London At an early age Street became deeply interested in the principles of Gothic architecture, and devoted an unsparing amount of time and labour to studying and sketching the finest examples of mediæval buildings in England and on the Continent He was a draughtsman of a very high order, his sketches are masterpieces of spirit and brilliant touch In 1855 he published a very careful and well illustrated work on *The Brick and Marble Architecture of Northern Italy*, and in 1865 a book on *The Gothic Architecture of Spain*, with very beautiful drawings by his own hand Street's personal taste led him in most cases to select for his design the 13th-century Gothic of England or France, his knowledge of which was very great, especially in the skilful use of rich mouldings By far the majority of the buildings erected by him were for ecclesiastical uses, the chief being the convent of East Grinstead, the theological college at Cuddesden, and a very large number of churches, such as St Philip and St James's at Oxford, St John's at Torquay, All Saints at Clifton, St Saviour's at Eastbourne, St Margaret's at Liverpool, and St Mary Magdalene, Paddington His largest works were the nave of Bristol cathedral, the choir of the cathedral of Christ Church in Dublin, and, above all the new Courts of Justice in London, second only in architectural importance (during this century) to the Houses of Parliament After a prolonged competition Street was appointed architect to the Courts of Justice in 1868, but the building was not complete at the time of his death in December 1881 A great deal of somewhat unfair criticism has been lavished on this building, but it should be remembered that Street was much hampered both by want of a sufficiently large site and by petty economies in money insisted on by the commissioner of works Though perhaps deficient in unity of composition, this great building possesses much grace in its separate parts, and has great refinement of detail throughout Street was elected an associate of the Royal Academy in 1866 and R A in 1871, at the time of his death he was professor of history to the Royal Academy, and had just finished a very interesting course of lectures on the development of mediæval architecture He was also a member of the Royal Academy of Vienna, and a knight of the Legion of Honour His somewhat sudden death, on December 18, 1881, was hastened by over-work and professional worries connected with the erection of the law courts He was buried in the nave of Westminster Abbey, where his grave is marked by a handsome sepulchral brass designed by Mr Bodley

STRENGTH OF MATERIALS

1 THE name "strength of materials" is given to that part of the theory of engineering which deals with the nature and effects of stresses in the parts of engineering structures Its principal object is to determine the proper size and form of pieces which have to bear given loads, or, conversely, to determine the loads which can be safely applied to pieces whose dimensions and arrangement are already given It also treats of the relation between the applied loads and the changes of form which they cause The subject comprises experimental investigation of the properties of materials as to strength and elasticity, and mathematical discussion of the stresses in ties, struts, beams, shafts, and other elements of structures and machines

Stress

2 Stress is the mutual action at the surface of contact between two bodies, or two imaginary parts of a body, whereby each of the two exerts a force upon the other Thus, when a stone lies on the ground there is at the surface of contact a stress, one aspect of which is the force directed downwards with which the stone pushes the ground, and the other aspect is the equal force directed upwards with which the ground pushes the stone A body is said to be in a state of stress when there is a stress between the two parts which lie on opposite sides of an imaginary surface of section A pillar or block supporting a weight is in a state of stress because at any cross section the part above the section pushes down against the part below, and the part below pushes up against the part above A stretched rope is in a state of stress, because at any cross section the part on each side is pulling the part on the other side with a force in the direction of the rope's length A plate of metal that is being cut in a shearing machine is in a state of stress, because at the plane which is about to become the plane of actual section the portion of metal on each side is tending to drag the portion on the other side with a force in that plane

State of stress

Normal and tangential stress

3 In a solid body which is in a state of stress the direction of stress at an imaginary surface of division may be normal, oblique, or tangential to the surface When oblique it is often conveniently treated as consisting of a normal and a tangential component Normal stress may be either push (compressive stress) or pull (tensile stress) Stress which is tangential to the surface is called shearing stress Oblique stress may be regarded as so much push or pull along with so much shearing stress The amount of stress per unit of surface is called the intensity of stress Stress is said to be uniformly distributed over a surface when each fraction of the area of surface bears a corresponding fraction of the whole stress If a stress P is uniformly distributed over a plane surface of area S, the intensity is P/S If the stress is not uniformly distributed, the intensity at any point is $\delta P/\delta S$, where δP is the amount of stress on an indefinitely small area δS at the point considered For practical purposes intensity of stress is usually expressed in tons weight per square inch, pounds weight per square inch, or kilogrammes weight per square millimetre or per square centimetre [1]

Simple longitudinal stress

4 The simplest possible state of stress is that of a short pillar or block compressed by opposite forces applied at its ends, or that of a stretched rope or other tie In these cases the stress is wholly in one direction, that of the length These states may be distinguished as simple longitudinal push and simple longitudinal pull In them there is no stress on planes parallel to the direction of the applied forces

Compound stress

A more complex state of stress occurs if the block is compressed or extended by forces applied to a pair of opposite sides, as well as by forces applied to its ends,—that is to say, if two simple longitudinal stresses in different directions act together A still more complex state occurs if a third stress be applied to the remaining pair of sides It may be shown that any state of stress which can possibly exist at any point of a body may be produced by the joint action of three simple pull or push stresses in three suitably chosen directions at right angles to each other [2] These three are

[1] One ton per sq in =2240 lb per sq in =1 511 kilos per sq mm
[2] See Elasticity, vol vii p 819

called principal stresses, and their directions are called the axes of principal stress These axes have the important property that the intensity of stress along one of them is greater, and along another it is less, than in any other direction These are called respectively the axes of greatest and least principal stress

Fig 1

Resolution of stress 5 Returning now to the case of a single simple longitudinal stress, let AB (fig 1) be a portion of a tie or a strut which is being pulled or pushed in the direction of the axis AB with a total stress P On any plane CD taken at right angles to the axis we have a normal pull or push of intensity $p = \mathrm{P/S}$, S being the area of the normal cross section On a plane EF whose normal is inclined to the axis at an angle θ we have a stress still in the direction of the axis, and therefore oblique to the plane EF, of intensity P/S′, where S′ is the area of the surface EF, or $\mathrm{S}/\cos\theta$ The whole stress P on EF may be resolved into two components, one normal to EF, and the other a shearing stress tangential to EF The normal component (P_n, fig 2) is $\mathrm{P}\cos\theta$, the tangential component (P_t) is $\mathrm{P}\sin\theta$ Hence the intensity of normal pull or push on EF, or p_n, is $p\cos^2\theta$, and the intensity of shearing stress on EF, or p_t, is $p\sin\theta\cos\theta$ This expression makes p_t a maximum when $\theta = 45°$ planes inclined at 45° to the axis are called planes of maximum shearing stress, the intensity of shearing stress on them is $\frac{1}{2}p$

Fig 2

Shearing stress 6 Shearing stress in one direction is necessarily accompanied by an equal intensity of shearing stress in another direction at right angles to the first To prove this it is sufficient to consider the equilibrium of an indefinitely small cube (fig 3), with one pair of sides parallel to the direction of the shearing stress P_t This stress, acting on two opposite sides, produces a couple which tends to rotate the cube No arrangement of normal stresses on any of the three pairs of sides of the cube can balance this couple, that can be done only by a shearing stress Q_t whose direction is at right angles to the first stress P_t and to the surface on which P_t acts, and whose intensity is the same as that of P_t The shearing stresses P_t and Q_t may exist alone, or as components of oblique stress

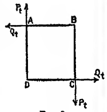

Fig 3

7 If they exist alone, the material is said to be in a state of simple shearing stress This state of stress may be otherwise described by reference to the stresses on diagonal planes of the cube ABCD Thus P_t and Q_t produce a normal stress R on a diagonal plane, and the equilibrium of the triangular prism (fig 4) requires that $\mathrm{R} = \mathrm{P}_t\sqrt{2}$ But R acts on a surface which is greater than each of the sides in the ratio of $\sqrt{2} : 1$ The intensity of normal stress on the diagonal plane

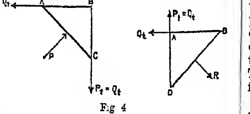

Fig 4

AC is therefore the same as the intensity of shearing stress on AB or BC The same considerations apply to the other diagonal plane BD at right angles to AC, with this difference, that the stress on it is normal pull instead of push Hence we may regard a state of simple shearing stress as compounded of two simple longitudinal stresses, one of push and one of pull, at right angles to each other, of equal intensity, and inclined at 45° to the direction of the shearing stress

Strain 8 STRAIN is the change of shape produced by stress If the stress is a simple longitudinal pull, the strain consists of lengthening in the direction of the pull, accompanied by contraction in both directions at right angles to the pull If the stress is a simple push, the strain consists of shortening in the direction of the push and expansion in both directions at right angles to that, the stress and the strain are then exactly the reverse of what they are in the case of simple pull If the stress is one of simple shearing, the strain consists of a distortion such as would be produced by the sliding of layers in the direction of the shearing stresses

A material is elastic with regard to any applied stress if the strain disappears when the stress is removed Strain which persists after the stress that produced it is removed is called permanent set For brevity, it is convenient to speak of strain which disappears when the stress is removed as elastic strain

Limits of elasticity 9 Actual materials are generally very perfectly elastic with regard to small stresses, and very imperfectly elastic with regard to great stresses If the applied stress is less than a certain limit, the strain is in general small in amount, and disappears wholly or almost wholly when the stress is removed If the applied stress exceeds this limit, the strain is, in general, much greater than before, and the principal part of it is found, when the stress is removed, to consist of permanent set The limits of stress within which strain is wholly or almost wholly elastic are called limits of elasticity

For any particular mode of stress the limit of elasticity is much more sharply defined in some materials than in others When well defined it may readily be recognized in the testing of a sample from the fact that after the stress exceeds the limit of elasticity the strain begins to increase in a much more rapid ratio to the stress than before This characteristic goes along with the one already mentioned, that up to the limit the strain is wholly or almost wholly elastic

Hooke's law 10 Within the limits of elasticity the strain produced by a stress of any one kind is proportional to the stress producing it This is Hooke's law, enunciated by him in 1676

In applying Hooke's law to the case of simple longitudinal stress, —such as the case of a bar stretched by simple longitudinal pull,— we may measure the state of strain by the change of length per unit of original length which the bar undergoes when stressed Let the original length be l, and let the whole change of length be δl when a stress is applied whose intensity p is within the elastic limit Then the strain is measured by $\delta l/l$, and this by Hooke's law is proportional to p This may be written

$$\delta l / l = p / \mathrm{E},$$

where E is a constant for the particular material considered The same value of E applies to push and to pull, these modes of stress being essentially continuous, and differing only in sign

Young's modulus 11 This constant E is called the modulus of longitudinal extensibility, or Young's modulus Its value, which is expressed in the same units as are used to express intensity of stress, may be measured directly by exposing a long sample of the material to longitudinal pull and noting the extension, or indirectly by measuring the flexure of a loaded beam of the material, or by experiments on the frequency of vibrations It is frequently spoken of by engineers simply as the modulus of elasticity, but this name is too general, as there are other moduluses applicable to other modes of stress Since $\mathrm{E} = pl/\delta l$, the modulus may be defined as the ratio of the intensity of stress p to the longitudinal strain $\delta l/l$

Modulus of rigidity 12 In the case of simple shearing stress, the strain may be measured by the angle by which each of the four originally right angles in the square prism of fig 3 is altered by the distortion of the prism Let this angle be ϕ in radians, then by Hooke's law $p/\phi = \mathrm{C}$, where p is the intensity of shearing stress and C is a constant which measures the rigidity of the material C is called the modulus of rigidity, and is usually determined by experiments on torsion

Modulus of cubic compressibility 13 When three simple stresses of equal intensity p and of the same sign (all pulls or all pushes) are applied in three directions, the material (provided it be isotropic, that is to say, provided its properties are the same in all directions) suffers change of volume only, without distortion of form If the volume is V and the change of volume $\delta\mathrm{V}$, the ratio of the stress p to the strain $\delta\mathrm{V}/\mathrm{V}$ is called the modulus of cubic compressibility, and will be denoted by K The state of stress here considered is the only one possible in a fluid at rest The intensity of stress is equal in all directions

14 Of these three moduluses the one of most importance in engineering applications is Young's modulus E When a simple longitudinal pull or push of intensity p is applied to a piece, the longitudinal strain of extension or compression is p/E This is accompanied by a lateral contraction or expansion, in each transverse direction, whose amount may be written $p/\sigma\mathrm{E}$, where σ is the ratio of longitudinal to lateral strain It is shown in the article ELASTICITY, § 47, that $\mathrm{E} = \dfrac{9\mathrm{CK}}{3\mathrm{K}+\mathrm{C}}$ and $\sigma = \dfrac{2(3\mathrm{K}+\mathrm{C})}{3\mathrm{K}-2\mathrm{C}}$

Plastic strain 15 Beyond the limits of elasticity the relation of strain to stress becomes very indefinite Materials then exhibit, to a greater or less degree, the property of plasticity The strain is much affected by the length of time during which the stress has been in operation, and reaches its maximum, for any assigned stress, only after a long (probably an indefinitely long) time Finally, when the stress is sufficiently increased, the ratio of the increment of strain to the increment of stress becomes indefinitely great if time is given for the stress to take effect In other words, the substance then assumes what may be called a completely plastic state, it *flows* under the applied stress like a viscous liquid

Ultimate strength 16 The *ultimate strength* of a material with regard to any stated mode of stress is the stress required to produce rupture In reckoning ultimate strength, however, engineers take, not the actual intensity of stress at which rupture occurs, but the value which this intensity would have reached had rupture ensued without previous alteration of shape Thus, if a bar whose original cross section is 2 square inches breaks under a uniformly distributed pull of 60 tons, the ultimate tensile strength of the material is reckoned to be 30 tons per square inch, although the actual intensity of stress which produced rupture may have been much greater than this, owing to the contraction of the section previous to fracture The convenience of this usage will be obvious from an example Suppose that a piece

of material of the same quality be used in a structure under conditions which cause it to bear a simple pull of 6 tons per square inch, we conclude at once that the actual load is one fifth of that which would cause rupture, irrespective of the extent to which the material might contract in section if overstrained. The stresses which occur in engineering practice are, or ought to be, in all cases within the limits of elasticity, and within these limits the change of cross section caused by longitudinal pull or push is so small that it may be neglected in reckoning the intensity of stress.

Ultimate tensile strength and ultimate shearing strength are well defined, since these modes of stress (simple pull and simple shearing stress) lead to distinct fracture if the stress is sufficiently increased. Under compression some materials yield so continuously that their ultimate strength to resist compression can scarcely be specified; others show so distinct a fracture by crushing (§ 43 below) that their compressive strength may be determined with some precision. In what follows, the three kinds of ultimate strength will be designated by the symbols f_t, f_s, and f_c, for tension, shearing, and crushing respectively.

Some of the materials used in engineering, notably timber and wrought-iron, are so far from being isotropic that their strength is widely different for stresses in different directions. In the case of wrought-iron the process of rolling develops a fibrous structure on account of the presence of streaks of slag which become interspersed with the metal in puddling, and the tensile strength of a rolled plate is found to be considerably greater in the direction of rolling than across the plate. Steel plates, being rolled from a nearly homogeneous ingot, have nearly the same strength in both directions.

Factor of safety.

17. In applying a knowledge of the ultimate strength of materials to determine the proper sizes of parts in an engineering structure, these parts are proportioned so that the greatest intensity of stress (which for brevity is called the working stress) will be only a certain fraction of the ultimate strength. The ratio $\frac{\text{ultimate strength}}{\text{working stress}}$ is called the factor of safety.[1] The choice of a factor of safety depends on many considerations, such as the probable accuracy of the theory on which the calculation of working stress has been based, the uniformity of the material dealt with, and the extent to which its strength may be expected to conform to the assumed value or to the values determined by experiments on samples, the deviations from the specified dimensions which may be caused by bad workmanship, the probable accuracy in the estimation of loads, the extent to which the materials will deteriorate in time. The factor is rarely less than 3, is very commonly 4 or 5, and is sometimes as much as 12, or even more.

The ultimate strength for any one mode of stress, such as simple pull, has been found to depend on the time rate at which stress is applied; this will be noticed more fully later (§§ 28-34). It has also been found to depend very greatly on the extent and frequency of variation in the applied stress. A stress considerably less than the normal ultimate strength will suffice to break a piece when it is frequently applied and removed; a much smaller stress will cause rupture if its sign is frequently reversed; and hence in a structure which has to bear what is called live load the permissible intensity of stress is less than in a structure which has to bear only load and also on its frequency of variation (§§ 45, 46 below).

18. From an engineering point of view, the structural merit of a material, especially when live loads and possible shocks have to be sustained, depends not only on the ultimate strength but also on the extent to which the material will bear deformation without rupture. This characteristic is shown in tests made to determine tensile strength by the amount of ultimate elongation, and also by the contraction of the cross-section which occurs through the flow of the metal before rupture. It is often tested in other ways, such as by bending and unbending bars in a circle of specified radius, or by examining the effect of repeated blows. Tests by impact are generally made by causing a weight to fall through a regulated distance on a piece of the material supported as a beam.

19. Ordinary tests of strength are made by submitting the piece to direct pull, direct compression, bending, or torsion. Testing machines are frequently arranged so that they may apply any of these four modes of stress; tests by direct tension are the most common, Tests of strength.

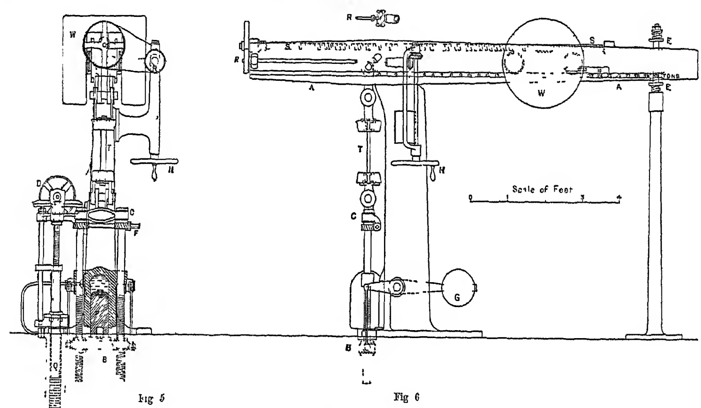

Fig. 5. Fig. 6.

Wicksteed's Single Lever Testing Machine.

and next to them come tests by bending. When the samples to be tested for tensile strength are mere wires, the stress may be applied directly by weights; for pieces of larger section some mechanical multiplication of force becomes necessary. Owing to the plasticity of the materials to be tested, the applied loads must be able to follow considerable change of form in the test piece: thus in testing the tensile strength of wrought iron or steel provision must be made for taking up the large extension of length which occurs before fracture. In most modern forms of large testing machines the loads are applied by means of hydraulic pressure acting on a piston or plunger to which one end of the specimen is secured, and the stress is measured by connecting the other end to a lever or system of levers provided with adjustable weights. In small machines, and also in some large ones, the stress is applied by screw gearing instead of by hydraulic pressure. Springs are sometimes used instead of weights to measure the stress, and another plan is to make one end of the specimen act on a diaphragm forming part of a hydrostatic pressure gauge (§ 23 below).

20. Figs. 5 and 6 show an excellent form of single lever testing machine designed by Mr J. H. Wicksteed,[2] in which the stress is applied by an hydraulic plunger and is measured by a lever or steelyard and a movable weight. The illustration shows a 30-ton machine, but machines of similar design have been built to exert a force of 100 tons or more. AA is the lever, on which there is a graduated scale. The stress on the test piece T is measured by a weight W of 1 ton (with an attached vernier scale), which is moved along the lever by a screw-shaft S; this screw shaft is driven by a belt from a parallel shaft R, which takes Single lever testing machine.

[1] French engineers usually estimate the permissible working stress as a certain fraction of the elastic strength (that is, of the stress which reaches the limit of elasticity), instead of estimating it as a certain fraction of the ultimate strength.

[2] *Proc. Inst. Mech. Eng.*, August 1882.

its motion, through bevel-wheels and a Hooke's joint in the axis of the fulcrum, from the hand-wheel H (The Hooke's joint in the shaft R is shown in a separate sketch above the lever in fig 6) The holder for the upper end of the sample hangs from a knife-edge three inches from the fulcrum of the lever The lower holder is jointed to a crosshead C, which is connected by two vertical screws to a lower cross head B, upon which the hydraulic plunger P, shown in section in fig 5, exerts its thrust G is a counterpoise which pushes up the plunger, when the water is allowed to escape Hydraulic pressure may be applied to P by pumps or by an accumulator In the present instance it is applied by means of an auxiliary plunger Q, which is pressed by screw gearing into an auxiliary cylinder Q is driven by a belt on the pulley D This puts stress on the specimen, and the weight W is then run out along the lever so that the lever is just kept floating between the stops E, E Before the test-piece is put in, the distance between the holders is regulated by means of the screws connecting the upper and lower cross heads C and B, these screws being turned by a handle applied at F Fig 7 is a section of one of the holders, showing how the test-piece T is gripped by serrated wedges The knife edges are made long enough to prevent the load on them ever exceeding 5 tons to the linear inch

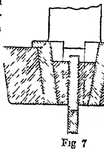

Fig 7

21 Another example of the single lever type is the Werder testing machine, much used on the continent of Europe In it the specimen is horizontal, one end is fixed, the other is attached to the short vertical arm of a bell crank lever, whose fulcrum is pushed out horizontally by an hydraulic ram [1] In many other testing machines a system of two, three, or more levers is employed to reduce the force between the specimen and the measuring weight Probably the earliest machine of this class was that of Major Wade,[2] in which one end of the specimen was held in a fixed support, and the stretch was taken up by screwing up the fulcrum plate of one of the levers In most multiple lever machines, however, the fulcrums are fixed, and the stress is applied to one end of the specimen by hydraulic power or by screw gearing, which of course takes up the stretch, as in the single lever machines already described Mr Kirkaldy, who was one of the earliest as well as one of the most assiduous workers in this field, applies in his 1,000,000 ℔ machine a horizontal hydraulic press directly to one end of the horizontal test piece The other end of the piece is connected to the short vertical arm of a bell crank lever, the long arm of this lever is horizontal, and is connected to a second lever to which weights are applied In some of Messrs Fairbanks's machines the multiple lever system is carried so far that the point of application of the weight moves 24,000 times as far as the point of attachment to the test-piece The same makers have employed a plan of adjusting automatically the position of the measuring weight, by making the scale lever complete an electric circuit when it rises or falls so that it starts an electric engine which runs the weight out or in [3] Generally the measuring weight is adjusted by hand In some, chiefly small, machines, the weight adjusts itself by means of another device It is fixed at one point of a lever which is arranged as a pendulum, so that, when the test piece is pulled by force applied at the other end, the pendulum lever is deflected from its originally vertical position and the weight acts with increasing leverage

Multiple lever testing machines

Multiple lever machines have the advantage that the measuring weight is reduced to a conveniently small value, and that it can be easily varied to suit test-pieces of different strengths On the other hand, their multiplicity of joints makes the leverage somewhat uncertain and increases friction Another drawback is the inertia of the working parts It is impossible to avoid oscillations of the levers and, to prevent them from producing important errors in the recorded stress, the inertia of the oscillating system should be minimized In a testing machine in which the specimen is directly loaded the inertia is simply that of the suspended weight M In a lever machine, which multiplies the weight n times, the weight applied to the lever is reduced to M/n, but its inertia, when referred to the test-piece, is $(M/n)\times n^2$ or Mn The inertia which is effective for producing oscillation is thus increased n times, so far as the weight alone is concerned, and this detrimental effect of leverage is increased by the inertia of the levers themselves The effect will be more serious the greater is the leverage n

22 Whitworth and others employ machines in which one end of the specimen is held in a fixed support, an hydraulic press acts on the other end, and the stress is calculated from the pressure of fluid in the press, this being observed by a pressure gauge. Machines of this class are open to the obvious objection that the friction of the hydraulic plunger causes a large and very uncertain difference between the force exerted by the fluid on the plunger and the force exerted by the plunger on the specimen It appears, however, that in the ordinary conditions of packing the friction is very nearly proportional to the fluid pressure, and its effect may therefore be allowed for with some exactness The method is not to be recommended for work requiring precision, unless the plunger be kept in constant rotation on its own axis during the test, in which case the effects of friction are almost entirely eliminated

23 In another important class of testing machines the stress (applied as before to one end of the piece, by gearing or by hydraulic pressure) is measured by connecting the other end to a flexible diaphragm, on which a liquid acts whose pressure is determined by a gauge Fig 8 shows a simple machine of this class (used in 1873 for testing wire by Sir W Thomson and the late Prof F Jenkin) The wire is stretched by means of a screw at the top, and pulls up the lower side of a hydrostatic bellows, water from the bellows rises in the gauge tube G, and its height measures the stress Fig 9 is Thomasset's testing machine, in which one end of the specimen is pulled by an hydraulic press A The other end acts through a bell crank lever B on a horizontal diaphragm C, consisting of a metallic plate and a flexible ring of india rubber The pressure on the diaphragm causes a column of mercury to rise in the gauge tube D The same principle is made use of in the testing machines of Chauvin and Marin

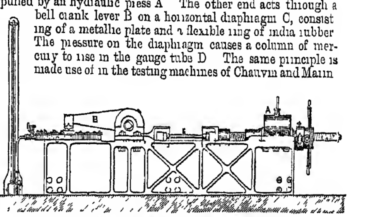

Fig 9 —Thomasset's Testing Machine

Darbel, Maillard,[4] and Bailey It has found its most important application in the remarkable testing machine of Watertown arsenal, built in 1879 by the U S Government to the designs of Mr A H Emery This is a horizontal machine, taking specimens of any length up to 30 feet, and exerting a pull of 360 tons or a push of 480 tons by an hydraulic press at one end The stress is taken at the other end by a group of four large vertical diaphragm presses, which communicate by small tubes with four similar small diaphragm presses in the scale case The pressure of these acts on a system of levers which terminates in the scale beam The joints and bearings of all the levers are made frictionless by using flexible steel connecting plates instead of knife-edges The total multiplication at the end of the scale beam is 420,000 [5]

Watertown machine

24 The results of tests are very commonly exhibited by means of stress strain diagrams, or diagrams showing the relation of strain to stress A few typical diagrams for wrought-iron and steel in tension are given in fig 10, the data for which are taken from tests of long rods by Mr Kirkaldy [6] Up to the elastic limit these diagrams show sensibly the same rate of extension for all the materials to which they refer Soon after the limit of elasticity is passed, a point, which has been called by Prof Kennedy the yield point, is reached, which is marked by a very sudden extension of

the specimen After this the extension becomes less rapid, then it continues at a fairly regular and gradually increasing rate, near the point of rupture the metal again begins to draw out rapidly

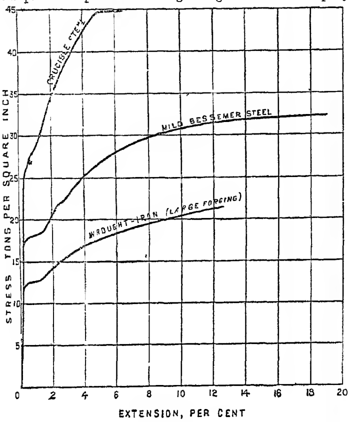

Fig 10

When this stage is reached rupture will occur through the flow of the metal, even if the load be somewhat decreased The diagram may in this way be made to come back towards the line of no load, by withdrawing a part of the load as the end of the test is approached (§ 29 below)

25 Fig 11 is a stress strain diagram for cast iron in extension and compression, taken from Hodgkinson's experiments[1] The extension was measured on a rod 50 feet long, the compression was also measured on a long rod, which was prevented from buckling by being supported in a trough with partitions The full line gives the strain produced by loading, it is continuous through the origin, showing that Young's modulus is the same for pull and push (Similar experiments on wrought-iron and steel in extension and compression have given the same result)

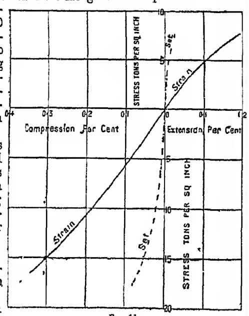

Fig 11

The broken line shows the set produced by each load Hodgkinson found that some set could be detected after even the smallest loads had been applied This is probably due to the existence of initial internal stress in the metal, produced by unequally rapid cooling in different portions of the cast bar A second loading of the same piece showed a much closer approach to perfect elasticity The elastic limit is, at the best, ill defined, but by the time the ultimate load is reached the set has become a more considerable part of the whole strain The pull curves in the diagram extend to the point of rupture, the compression curves are drawn only up to a stage at which the bar buckled (between the partitions) so much as to affect the results

Autographic recorders

26 Testing machines are now frequently fitted with autographic appliances for drawing strain diagrams When the load is measured by a weight travelling on a steelyard, the diagram may be drawn by connecting the weight with a drum by means of a wire or cord, so that the drum is made to revolve through angles proportional to the travel of the weight At the same time another wire, fastened to a clip near one end of the specimen, and passing over a pulley near the other end, draws a pencil through distances proportional to the strain, and so traces a diagram of stress and strain on a sheet of paper stretched round the drum Apparatus of this kind has been used by Messrs Fairbanks, Unwin, Aspinall, and others[2] In Mr Wicksteed's autographic recorder the stress is determined by reference, not to the load on the lever, but to the pressure in the hydraulic cylinder by which stress is applied The main cylinder is in communication with a small auxiliary hydraulic cylinder, the plunger of which is kept rotating to avoid friction at its packing This plunger abuts against a spring, so that the distance through which it is pushed out varies with the pressure in the main cylinder A drum covered with paper moves with the plunger under a fixed pencil, and is also caused to rotate by a wire from the specimen through distances proportional to the strain The scale of loads is calibrated by occasional reference to the weighted lever[3] In Prof Kennedy's machine autographic diagrams are drawn by applying the stress to the test-piece through an elastic master-bar of larger section The master bar is never strained beyond its elastic limit, and within that limit its extension furnishes an accurate measure of the stress, this gives motion to a pencil, which writes on a paper moved by the extension of the test-piece[4] In Prof Thurston's pendulum machine for torsion tests, a cam attached to the pendulum moves a pencil through distances proportional to the stress, while a paper drum attached to the other end of the test-piece turns under the pencil through distances proportional to the angle of twist[5]

27 The elastic extension or compression of a test piece of ordinary dimensions is so small as to require for its measurement refined methods which are seldom employed in everyday practical testing Measurements of this class must be made simultaneously on opposite sides of the test piece, to guard against error through the bending of the piece Microscopes and also various forms of micrometer calipers are used for the purpose[6] A method capable of great delicacy, which has been used by Bauschinger[7] and others, is to measure the strain by light reflected from a pair of small mirrors attached to rollers which turn as the specimen extends or contracts With apparatus of this kind it may be shown that iron, steel, or other materials with a well defined yield point begin to show a marked defect of elasticity at a somewhat lower stress The true elastic limit comes considerably earlier in the test than the point which usually passes by that name[8] Measurement of elastic strain

28 In testing a plastic material such as wrought iron or mild steel it is found that the behaviour of the metal depends very materially on the time rate at which stress is applied When once the elastic limit is passed the full strain corresponding to a given load is reached only after a perceptible time, sometimes even a long time If the load be increased to a value exceeding the elastic limit, and then kept constant, the metal will be seen to draw out (if the stress be one of pull), at first rapidly and then more slowly When the applied load is considerably less than the ultimate strength of the piece (as tested in the ordinary way by steady increment of load), it appears that this process of slow extension comes at last to an end On the other hand, when the applied load is nearly equal to the ultimate strength, the flow of the metal continues until rupture occurs Then, as in the former case, extension goes on at first quickly, then slowly, but, finally, instead of approaching an asymptotic limit, it quickens again as the piece approaches rupture The same phenomena are observed in the bending of timber and other materials when in the form of beams If, instead of being subjected to a constant load, a test piece is set in a constant condition of strain, it is found that the stress required to maintain this constant strain gradually decreases Viscosity.

29 The gradual flow which goes on under constant stress—approaching a limit if the stress is moderate in amount, and continuing without limit if the stress is sufficiently great—will still go on at a diminished rate if the amount of stress be reduced Thus, in the testing of soft iron or mild steel by a machine in which the stress is applied by hydraulic power, a stage is reached soon after the limit of elasticity is passed at which the metal begins to flow with great rapidity The pumps often do not keep pace with this, and the result is that, if the lever is to be kept floating, the weight on it must be run back Under this reduced stress the

flow continues, more slowly than before, until presently the pumps recover their lost ground and the increase of stress is resumed Again, near the point of rupture, the flow again becomes specially rapid, the weight on the lever has again to be run back, and the specimen finally breaks under a diminished load These features are well shown by fig 12, which is copied from the autographic diagram of a test of mild steel [1]

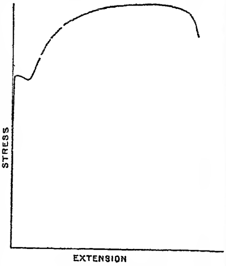

Fig 12 —Autographic Diagram for a test of mild steel

Hardening effect of permanent set

30 But it is not only through what we may call the viscosity of materials that the time rate of loading affects their behaviour under test In iron and steel, and probably in some other metals, time has another effect of a very remarkable kind Let the test be carried to any point *a* (fig 13) past the original limit of elasticity Let the load then be removed, during the first stages of this removal the material continues to stretch slightly, as has been explained above Let the load then be at once replaced and loading continued It will then be found that there is a new yield-point *b* at or near the value of the load formerly reached, up to this point there is little other than elastic strain The full line *bc* in fig 13 shows the subsequent behaviour of the piece But now let the experiment be repeated on another sample, with this difference, that an interval of time, of a few hours or more, is allowed to elapse after the load is removed and before it is replaced It will then be found that a process of hardening has been going on during this interval of rest, for, when the loading is continued, the new yield-point appears, not at *b* as formerly, but at a higher load *d* Other evidence that a change has taken place is afforded by the fact that the ultimate extension is reduced and the ultimate strength is increased (*e*, fig 13)

Influence of time

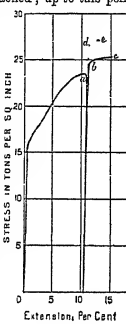

Fig 13

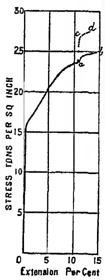

Fig 14

31 A similar and even more marked hardening occurs when a load (exceeding the original elastic limit), instead of being removed and replaced, is kept on for a sufficient length of time without change When loading is resumed a new yield-point is found only after a considerable addition has been made to the load The result is, as in the former case, to give greater ultimate strength and less ultimate elongation, Fig 14 exhibits two experiments of this kind, made with annealed iron wire A load of 23½ tons per square inch was reached in both cases, *ab* shows the result of continuing to load after an interval of five minutes, and *acd* after an interval of 45½ hours, the stress of 23½ tons being maintained during the interval in both cases

32 It must not be supposed that in a material hardened by strain the elasticity is perfect up to the yield points which are shown in fig 13 at *b* and *d* or in fig 14 at *c* In experiments made for this article, it has been found that, after a piece of very soft iron wire has been hardened (as in fig 14) by the continued application of a load which had caused stretching, if a small addition be made to the load (bringing it to a value between *a* and the new yield-point), although there is at first no apparent drawing out, nevertheless if time be given the wire begins again to draw, and a large amount of stretching at an increased pace may ensue In this way wires have been broken with loads considerably short of those which would have been required had the process of loading, from the point *a* onward, been continued at a moderately rapid rate A slow process of viscous deformation may in fact be occurring at the same time that the metal shows a quasi-elasticity with respect to rapid alteration of stress Bauschinger's micrometric experiments have shown that after a piece has been hardened by rest the true limit of elasticity, or the point at which Hooke's law begins to fail, comes far short of the yield-point He has also shown that a long interval of rest after the set has taken place produces a slow rise of the true limit of elasticity,[2] apparently a slower rise than the lapse of time causes in the yield point itself

33 In the testing of iron and steel the time during which any state of (pull) stress (exceeding the original elastic limit) exists affects the result in two somewhat antagonistic ways It augments extension, by giving the metal leisure to flow This may be called the viscous effect But, on the other hand, it reduces the amount of extension which subsequent greater loads will cause, and it increases the amount of load required for rupture in the way which has just been described This may be called the hardening effect When a piece is broken by continuous gradual increment of load, these two effects are occurring at all stages of the test If the viscous effect existed alone, or if the hardening effect were small, the material would show to greater advantage as regards elongation, and to less advantage as regards ultimate strength, the more slowly the load were applied Tin and lead may be cited as materials for which this is the case But when the hardening effect is relatively great, as in iron and steel, the material shows less elongation and a higher breaking strength the more slowly it is tested An excellent illustration of this is given by the following experiment of Mr Bottomley Pieces of iron wire, annealed and of exceptionally soft quality, when loaded at the rate of 1 lb in 5 minutes, broke with 44½ lb and stretched 27 per cent of their original length Other pieces of the same wire, loaded at the rate of 1 lb in 24 hours, broke with 47 lb and stretched less than 7 per cent [3] Again, it has been found that an excessively rapid application of stress (by the explosion of gun cotton) makes soft steel stretch twice as much as in ordinary testing [4] The case is very different, however, if the material has been previously hardened by strain It does not appear that such variations in the rate of loading as are liable to occur in practical tests of iron or steel have much influence on the extension or the strength, great as the effects of time are when the metal is loaded either much more slowly or much more quickly In fig 15 the results are shown of tests of two similar pieces of soft iron wire, one loaded to rupture in 4 minutes and the other at a rate about 5000 times slower

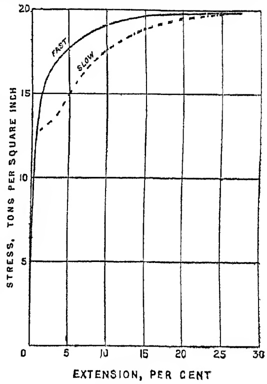

Fig 15

34 The hardening effect which intervals of rest from load or of constant load produce, once the primitive elastic limit is passed, has been examined by Beardsley,[5] Thurston,[5] Bauschinger,[6] Ewing,[7] and others The effect of even a few minutes' pause is perceptible, an hour or two of constant stress has a very marked influence, and after 24 hours or so there appears to be little further hardening The American Board found that iron bars, previously stressed to about 50,000 lb per square inch, gained in strength, by intervals of rest from stress, to the extent of about 9 per cent in one day, 16 per cent in three days, and 18 per cent in six months [8]

35 It may be concluded that, when a piece of metal has in any way received a permanent set by stress exceeding its limits of

[1] The increase of strain without increase of stress, which goes on without limit when a test-piece under tension approaches rupture, is a special case of the general phenomenon of "flow of solids," which has been exhibited, chiefly for compressive stresses, in a series of beautiful experiments by Tresca (*Mémoires sur l'Écoulement des Corps Solides*, also *Proc Inst Mech Eng*, 1867 and 1878)

[8] *Loc cit*, p 111

elasticity, it is hardened and (in some cases at least) its physical properties go on slowly changing for days or even months. Instances of the hardening effect of permanent set occur when plates or bars are rolled cold, hammered cold, or bent cold, or when wire is drawn. When a hole is punched in a plate the material contiguous to the hole is severely distorted by shear, and is so much hardened in consequence that when a strip containing the punched hole is broken by tensile stress the hardened portion, being unable to extend so much as the rest, receives an undue proportion of the stress, and the strip breaks with a smaller load than it would have borne had the stress been uniformly distributed. This bad effect of punching is especially noticeable in thick plates of mild steel. It disappears when a narrow ring of material surrounding the hole is removed by means of a rimer, so that the material that is left is homogeneous. Another remarkable instance of the same kind of action is seen when a mild steel plate which is to be tested by bending has a piece cut from its edge by a shearing machine. The result of the shear is that the metal close to the edge is hardened, and, when the plate is bent, this part, being unable to stretch like the rest, starts a crack or tear which quickly spreads across the plate on account of the fact that in the metal at the end of the crack there is an enormously high local intensity of stress (see ELASTICITY, § 72). By the simple expedient of planing off the hardened edge before bending the plate homogeneity is restored, and the plate will then bend without damage.

Annealing.

36. The hardening effect of strain is removed by the process of annealing, that is, by heating to redness and cooling slowly. In iron, very mild steel, and most other metals the rate of cooling is a matter of indifference, but in steel that contains more than about 0.2 per cent. of carbon another kind of hardening is produced if the metal, after being heated to redness, is cooled suddenly. When the proportion of carbon is considerably greater than this, steel may be rendered excessively hard and brittle ("glass-hard") by sudden cooling from a red heat. Further, by being subsequently heated to a moderate temperature, it may be deprived of some of this hardness and rendered elastic through a wide range of strain. This process is called the tempering of steel; its effects depend on the temperature to which the steel is heated after being hardened, and the grade of temper which is acquired is usually specified by the colour (blue, straw, &c.) which appears on a clean surface of the metal during this heating, through the formation of a film of oxide. In the ordinary process of rolling plates or bars of iron or mild steel the metal leaves the rolls at so high a temperature that it is virtually annealed, or pretty nearly so.[1] The case is different with plates and bars that are rolled cold. They, like wire supplied in the hard drawn state (that is, without being annealed after it leaves the draw-plate), exhibit the higher strength and greatly reduced plasticity which result from permanent set.

Hardening and tempering of steel.

Contraction of section at rupture.

37. The extension which occurs when a bar of uniform section is pulled is at first general, and is distributed with some approach to uniformity over the length of the bar. Before the bar breaks, however, a large additional amount of local extension occurs at and near the place of rupture. The material flows in that neighbourhood much more than in other parts of the bar, and the section is much more contracted there than elsewhere. The contraction of area at fracture is frequently stated as one of the results of a test, and is a useful index to the quality of materials. If a flaw is present sufficient to determine the section at which rupture shall occur the contraction of area will in general be distinctly diminished as compared with the contraction in a specimen free from flaws, although little reduction may be noted in the total extension of the piece. Local extension and contraction of area are almost absent in cast iron and hard steel; on the other hand they are specially prominent in wrought-iron, mild steel, and other metals

Fig. 16.

that combine plasticity with high tensile strength. An example is shown in fig. 16, which is copied from a photograph of a broken test-piece of Whitworth soft fluid compressed steel.

38. Experiments with long rods show that the general extension which occurs in parts of the bar not near the break is somewhat irregular;[2] it exhibits here and there incipient local stretching, which has stopped without leading to rupture. This is of course due in the first instance to want of homogeneity. It may be supposed that when local stretching begins at any point in the earlier stages of the test it is checked by the hardening effect of the strain, until, finally, under greater load, a stage is reached in which the extension at one place goes on so fast that the hardening effect cannot keep pace with the increase in intensity of stress which results from diminution of area; the local extension is then unstable, and rupture ensues. Even at this stage a pause in the loading, and an interval of relief from stress, may harden the locally stretched part enough to make rupture occur somewhere else when the loading is continued.

Influence of local stretch on total elongation.

39. Local stretching causes the percentage of elongation which a test piece exhibits before rupture (an important quantity in engineers' specifications) to vary greatly with the length and section of the piece tested. It is very usual to specify the length which is to exhibit an assigned percentage of elongation. This, however, is not enough; the percentage obviously depends on the relation of the transverse dimensions to the length. A fine wire of iron or steel, say 8 inches long, will stretch little more in proportion to its length than a very long wire of the same quality. An 8 inch bar, say 1 inch in diameter, will show something like twice as much the percentage of elongation as a very long rod. The experiments of M. Barba[3] show that, in material of uniform quality, the percentage of extension is constant for test pieces of similar form, that is to say, for pieces of various size in which the transverse dimensions are varied in the same proportion as the length. It is to be regretted that in ordinary testing it is not practicable to reduce the pieces to a standard form, with one proportion of transverse dimensions to length, since an arbitrary choice of length and cross section gives results which are incapable of direct comparison with one another.

Influence of form on strength.

40. The form chosen for test pieces in tension tests affects not only the extension but also the ultimate strength. In the first place, if there is a sudden or rapid change in the area of cross section at any part of the length under tension (as at AB, fig. 17), the stress will not be uniformly distributed there. The intensity will be greatest at the edges A and B, and the piece will, in consequence, pass its elastic limit at a less value of the total load than would be the case if the change from the larger to the smaller section were gradual. In a non ductile material, rupture will for the same reason take place at AB, with a less total load than would otherwise be borne. On the other hand, with a sufficiently ductile material, although the section AB is the first to be permanently deformed, rupture will preferably take place at some section not near AB, because at and near AB the contraction of sectional area which precedes rupture is partly prevented by the presence of the projecting portions C and D. Hence, too, with a ductile material samples such as those of fig. 18, in which the part of smallest section between the shoulders or enlarged ends of the piece is short, will break with a greater load than could be borne by long uniform rods of the same section. In good wrought iron and mild steel the flow of metal preceding rupture and causing local contraction of section extends over a length six or eight times the width of the piece, and, if the length throughout which the section is uniform be materially less than this, the process of flow will be rendered more difficult and the breaking load of the sample will be raised.[4]

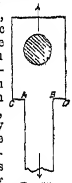

Fig. 17.

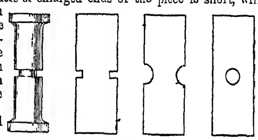

Fig. 18.

These considerations have of course a wider application than to the mere interpretation of special tests. An important practical case is that of riveted joints, in which the metal left between the rivet-holes is subjected to tensile stress. It is found to bear, per square inch, a greater pull than would be borne by a strip of the same plate, if the strip were tested in the usual way with uniform section throughout a length great enough to allow complete freedom of local flow.[5]

Comparative strength of long and short rods.

41. The tensile strength of long rods is affected by the length in quite a different way. With a perfectly homogeneous material, no difference should be found in the strength of rods of equal

[1] In several of Mr Kirkaldy's papers, a comparison is given of the elastic limit, ultimate strength, and ultimate extension of samples which were annealed before testing, and of samples which were tested in the commercial state; in general the annealed samples are distinctly, though not very materially, softer than the others (*On the Relative Properties of Wrought Iron Plates from Essex and Yorkshire*, London, 1876; also *Experiments on Fagersta Steel*, London, 1873).

[2] See Kirkaldy's *Experiments on Fagersta Steel*, London, 1873; also *Report of the Steel Committee*, part i.

[3] *Mem. de la Soc. des Ing. Civ.*, 1880; see also a paper by Mr W. Hackney, "On the Adoption of Standard Forms of Test Pieces," *Min. Proc. Inst. C.E.*, 1884.

[4] The greater strength of nicked or grooved specimens seems to have been first remarked by Mr Kirkaldy (*Experiments on Wrought Iron and Steel*, p. 74; also *Experiments on Fagersta Steel*, p. 27). See also a paper by Mr E. Richards, on tests of mild steel, *Jour. Iron and Steel Inst.*, 1882.

[5] See Kennedy's "Reports on Rivetted Joints," *Proc. Inst. Mech. Eng.*, 1881-5. In the case of mild steel plates a drilled strip may have as much as 12 per cent. more tensile strength per square inch than an undrilled strip. With punched holes, on the other hand, the remaining metal is much weakened, for the reason referred to in § 35.

sectional area and of different lengths, provided the length of both were great enough to prevent the action described in § 40 from affecting the result. But, since no material is perfectly homogeneous, the longer rod will in general be the weaker, offering as it does more chances of a weak place, and the probable defect of strength in the long rod will depend on the degree of variability of the material. When this has been established by numerous tests of short samples, the strength which a rod of any assigned length may be expected to possess can be calculated by an application of the theory of probabilities. A theory of the strength of long bars has been worked out on this basis by Prof Chaplin,[1] and has been experimentally confirmed by tests of long and short samples of wire. The theory does not apply when the length is so small that the action of § 40 enters into the case, and the experimental data on which it is based must be taken from tests of samples long enough to exclude that action.

Fig 19

Fracture by tension. 42. In tension tests, rupture may occur, as in fig 19, by direct separation over a surface which is nearly plane and normal to the line of stress. This is usual in hard steel and other comparatively non ductile materials. Or it may occur by shearing along an oblique plane, as in fig 20, which shows the fracture of a piece of steel softer than the specimen of fig 19. In very ductile samples these two modes of rupture are frequently found in combination, as in fig 21, where a central core is broken by direct tension while round it is a ring over which separation has taken place by shearing. In this instance the ring is in two parts, one above and one below the surface of rupture of the central flat core. In other instances, such as that of the sample shown in fig 16, the shearing forms a continuous cone or crater round a flat core.

Fig 20

Fig 21

Fracture by compression. 43. In compression tests of a plastic material, such as mild steel, a process of flow may go on without limit, the piece (which must of course be short, to avoid buckling) shortens and bulges out in the form of a cask. This is illustrated by fig 22 (from one of Fairbairn's experiments), which shows the compression of a round block of steel (the original height and diameter of which are shown by the dotted lines) by a load equal to 100 tons per square inch of original sectional area. The surface over which the stress is distributed becomes enlarged, and the total load must be increased in a corresponding degree to maintain the process of flow.[2] The bulging often produces longitudinal cracks, as in the figure, especially when the material is fibrous as well as plastic (as in the case of wrought iron). A brittle material, such as cast iron brick, or stone, yields by shearing on inclined planes as in figs 23 and 24, which are taken from Hodgkinson's experiments on cast iron.[3] The simplest fracture of this kind is exemplified by fig 23, where a single surface (approximately a plane) of shear divides the compressed block into two wedges. With cast iron the slope of the plane is such that this simple mode of fracture can take place only if the height of the block is not less than about $\frac{3}{2}$ the width of the base. When the height is less the action is more complex. Shearing must then take place over more than one plane, as in fig 24, so that cones or wedges are formed by which the surrounding portions of the block are split off. The stress required to crush the block is consequently greater than if the height were sufficient for shearing in a single plane.

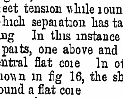

Fig 22

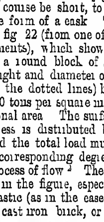

Fig 23

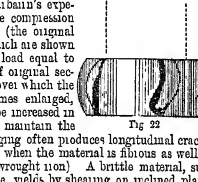

Fig 24

Plane of shear. 44. The inclination of the surfaces of shear, when fracture takes place by shearing under a simple stress of pull or push, is a matter of much interest, throwing some light on the question of how the resistance which a material exerts to stress of one kind is affected by the presence of stress of another kind,—a question scarcely touched by direct experiment. At the shorn surface there is, in the case of tension tests, a normal pull as well as a shearing stress, and in the case of compression tests a normal push as well as shearing stress. If this normal component were absent the material (assuming it to be isotropic) would shear in the surface of greatest shearing stress, which, as we have seen in § 5, is a surface inclined at 45° to the axis. In fact, however, it does not shear on this surface. Hodgkinson's experiments on the compression of cast iron give surfaces of shear whose normal is inclined at about 55° to the axis of stress,[4] and Kirkaldy's, on the tension of steel, show that when rupture takes place by shear the normal to the surface is inclined at about 25° to the axis.[4] These results show that normal pull diminishes resistance to shearing and normal push increases resistance to shearing. In the case of cast iron under compression, the material prefers to shear on a section where the intensity of shearing stress is only 0 94 of its value on the surface of maximum shearing stress (inclined at 45°), but where the normal push is reduced to 0 66 of its value on the surface of maximum shearing stress.

Fatigue of metals. 45. *Fatigue of Metals*.—A matter of great practical as well as scientific interest is the weakening which materials undergo by repeated changes in their state of stress. It appears that in some if not in all materials a limited amount of stress-variation may be repeated time after time without appreciable deterioration in the strength of the piece, in the balance spring of a watch, for instance, tension and compression succeed each other some 150 millions of times in a year, and the spring works for years without apparent injury. In such cases the stresses lie well within the elastic limits. On the other hand, the toughest bar breaks after a small number of bendings to and fro, when these pass the elastic limits, although the stress may have a value greatly short of the normal ultimate strength. A laborious research by Wöhler,[5] extending over twelve years, has given much important information regarding the effects on iron and steel of very numerous repeated alternations of stress from positive to negative, or between a higher and a lower value without change of sign. (Wohler's experiments.) By means of ingeniously contrived machines he submitted test-pieces to direct pull, alternated with complete or partial relaxation from pull, to repeated bending in one direction and also in opposite directions, and to repeated twisting towards one side and towards opposite sides. The results show that a stress greatly less than the ultimate strength (as tested in the usual way by a single application of load continued to rupture) is sufficient to break a piece if it be often enough removed and restored, or even alternated with a less stress of the same kind. In that case, however, the variation of stress being less, the number of repetitions required to produce rupture is greater. In general, the number of repetitions required to produce rupture is increased by reducing the range through which the stress is varied, or by lowering the upper limit of that range. If the greatest stress be chosen small enough, it may be reduced, removed, or even reversed many million times without destroying the piece. Wohler's results are best shown by quoting a few figures selected from his experiments. The stresses are stated in centners per square zoll,[6] in the case of bars subjected to bending they refer to the top and bottom sides, which are the most stressed parts of the bar.

I. Iron bar in direct tension —

Stress Max	Stress Min	Number of Applications causing Rupture	Stress Max	Stress Min	Number of Applications causing Rupture
480	0	800	320	0	10,141,645
440	0	106,901			
400	0	340,853	440	200	2,373,424
360	0	450,852	440	240	Not broken with 4 millions

II. Iron bar bent by transverse load —

Stress Max	Stress Min	Number of Bendings causing Rupture	Stress Max	Stress Min	Number of Bendings causing Rupture
550	0	169 750	400	0	1,320,000
500	0	420 000	350	0	4,035 400
450	0	481 950	300	0	Not broken with 48 millions

III. Steel bar bent by transverse load —

Stress Max	Stress Min	Number of Bendings causing Rupture	Stress Max	Stress Min	Number of Bendings causing Rupture
900	0	72,450	900	400	225,300
900	200	81,200	900	500	764,900—mean of two trials
900	300	156,200	900	600	Not broken with $33\frac{1}{2}$ mills

[6] According to Bauschinger (*loc cit*, p 44), the centner per square zoll in which Wöhler gives his results is equivalent to 6 837 kilos per square cm, or 0 0434 ton per square inch

IV Iron bar bent by supporting at one end, the other end being loaded, alternations of stress from pull to push caused by rotating the bar —

Stress From + to −	Number of Rotations causing Rupture	Stress From + to −	Number of Rotations causing Rupture
320	56,430	220	3,632,588
300	99,000	200	4,917,992
280	183,145	180	19,186,791
260	479,490	160	Not broken with 132¼ millions
240	909,810		

46 From these and other experiments Wohler concluded that the wrought iron to which the tests refer could probably bear an indefinite number of stress changes between the limits stated (in round numbers) in the following table (the ultimate tensile strength was about 19½ tons per square inch) —

	Stress in Tons per Sq Inch
From pull to push	+7 to −7
From pull to no stress	13 to 0
From pull to less pull	19 to 10½

Hence it appears that the actual strength of this material varies in a ratio which may be roughly given as 3 2 1 in the three cases of (*a*) steady pull, (*b*) pull alternating with no stress, very many times repeated, and (*c*) pull alternating with push, very many times repeated Factors of safety applicable to the three cases might therefore rationally stand to one another in the ratio of 1 2 3 For steel Wohler obtained results of a generally similar kind His experiments were repeated by Spangenberg, who extended the inquiry to brass, gun-metal, and phosphor bronze [1] On the basis of Wohler's results formulas have been devised by Launhardt, Weyrauch, and others to express the probable actual strength of metals under assigned variations of stress, these are, of course, of a merely empirical character, and the data are not yet extensive enough to give them much value [2]

47 Wohler's experiments, dealing, as all experiments must, with a finite number of stress changes, leave it an open question whether there are any limits within which a state of stress might be indefinitely often varied without finally destroying the material It is natural to suppose that a material possessing perfect elasticity would suffer no deterioration from stress changes lying within limits up to which the elasticity is perfect But these limits, if they exist at all, are probably very narrow Indeed, in the case of iron, there is indirect evidence that all alteration of stress whatsoever affects the molecular structure in a way not consistent with the notion of perfect elasticity When the state of stress in iron is varied, however slowly and however little, the magnetic and thermo electric qualities of the metal are found to change in an essentially irreversible manner [3] Every variation leaves its mark on the quality of the piece, the actual quality at any time is a function of all the states of stress in which the piece has previously been placed It can scarcely be doubted that sufficiently refined methods of experiment would detect a similar want of reversibility in the mechanical effects of stress, even when alterations of stress occur slowly enough to escape the effects of viscosity which have been examined by Sir William Thomson and discussed under ELASTICITY (vol vii pp 802 *sq*) In any case, the viscosity investigated by Thomson causes such stress-changes as occur rapidly to do work on the material, and the destructive effect of repeated changes may be due in great part to this cause His experiments show that rapid stress-changes often repeated do produce a cumulative effect in reducing the modulus of elasticity, and it is very probable that this fatigue of elasticity is associated with fatigue of strength

There are as yet no experiments showing how far fatigue of strength is affected by the frequency, as distinguished from the mere number, of the stress changes, nor whether a period of rest, after fatigue has been induced, restores strength That it does so may be conjectured from Thomson's discovery that rest restores elasticity after elastic fatigue The conjecture is strengthened by Bauschinger's discovery that, after a permanent set has been produced and a period of rest follows, the apparent limit of elasticity (in the strict sense of that term) rises slowly with the lapse of time Both questions are of obvious practical interest [4]

48 When a strain is produced within the limits to which Hooke's law applies, the work done in producing it is half the product of the stress into the strain A load applied to a piece suddenly, but without impact, does an amount of work in straining the piece which is measured by the weight of the load into the distance it sinks in consequence of the strain Hence, provided this strain falls within the elastic limit, the strain and the stress are twice as great as the same load would produce when in equilibrium Instances of load applied with complete suddenness, and yet without shock, are rare, but it is a common case for loads to be applied so rapidly that the stress reaches a value intermediate between that due to a static load and the double stress due to the same load applied at once Thus the Railway Commissioners found that certain bridges were deflected by a train passing at a speed of 50 miles per hour ⅐ more than by the same load at rest [5] The fact that a "live" load produces greater stress than a dead load is of course to be distinguished from the question Wohler's experiments deal with—the greater destructiveness of the intermitted or varied stress which a live load causes In many cases engineers allow in one operation for these quite independent influences of a live load by choosing a higher factor of safety for the live than for the dead part of the whole load on a structure, or (what is the same thing) by multiplying the live load by a coefficient (often 1½), adding the product to the dead load, and treating the sum as if all were dead load Strain produced by "live" load

49 A useful application of diagrams showing the relation of strain to stress is to determine the amount of work done in straining a piece in any assigned way The term "resilience" is conveniently used to specify the amount of work done when the strain just reaches the corresponding elastic limit Thus a rod in simple tension or simple compression has a resilience per unit of volume $=f^2/2E$, where f is the greatest elastic pull or push A blow whose energy exceeds the resilience (reckoned for the kind of stress to which the blow gives rise) must in the most favourable case produce a permanent set, in less favourable cases local permanent set will be produced although the energy of the blow is less than the resilience, in consequence of the strain being unequally distributed In a plastic material a strain exceeding the limit of elasticity absorbs a relatively large amount of energy, and generally increases the resilience for subsequent strains Fracture under successive blows, as in the testing of rails by placing them as beams on two supports, and allowing a weight to fall in the middle from a given height, results from the accumulated set which is brought about by the energy of each blow exceeding the resilience Resilience

50 In an important paper [6] which is reprinted in the article ELASTICITY, and should be carefully studied in this connexion, Prof James Thomson has pointed out that the effect of any externally applied load depends, to a very material extent, on whether there is or is not initial internal stress, or, in other words, whether the loaded piece is initially in what Prof Hearson has called a state of ease Internal stress, existing without the application of force from without the piece, must satisfy the condition that its resultant vanishes over any complete cross-section It may exist in consequence of set caused by previously applied forces (a case of which instances are given below), or in consequence of previous temperature changes, as in cast-iron, which is thrown into a state of internal stress by unequally rapid cooling of the mass Thus in (say) a spherical casting an outside shell solidifies first, and has become partially contracted by cooling by the time the inside has become solid The inside then contracts, and its contraction is resisted by the shell, which is thereby compressed in a tangential direction, while the metal in the interior is pulled in the direction of the radius Allusion has already been made to the fact, pointed out by J Thomson, that the defect of elasticity under small loads which Hodgkinson discovered in cast iron is probably due to initial stress In plastic metal a nearly complete state of ease is brought about by annealing, even annealed pieces, however, sometimes show, in the first loading, small defects of elasticity, which are probably due to initial stress, as they disappear when the load is reapplied Internal stress

51 Little is exactly known with regard to the effect of temperature on the strength of materials Some metals, notably iron or steel containing much phosphorus, show a marked increase in brittleness at low temperatures, or "cold shortness" Experiments on the tensile strength of wrought-iron and steel show in general little variation within the usual atmospheric range of heat and cold The tensile strength appears to be slightly reduced at very low temperatures, and to reach a maximum when the metal is warmed to a temperature between 100° C and 200° C When the temperature exceeds 300° C the tensile strength begins to fall off rapidly, and at 1000° C it is less than one-tenth of the normal value [7] Reference may be made, in this connexion, to the effect which a "blue heat," or temperature short of red heat, is believed to have on the plasticity and strength of iron, and more especially of mild steel It appears that steel plates and bars bent or otherwise Effect of temperature on the strength

worked at a blue heat not only run a much more serious risk of fracture in the process than when worked either cold or red hot, but become deteriorated so that brittleness may afterwards show itself when the metal is cold [1]

Experimental data

52 The following table gives a few representative data regarding the strength of the more important materials used in engineering (the figures are gathered from the writings of Barlow, Hodgkinson, Kirkaldy, Thurston, Rankine, Unwin, Clark, and others) —

	Ultimate Strength Tons per Square Inch			Elasticity Tons per sq in	
	f_t	f_c	f_s	Young's Modulus E	Mod of Rigidity C
Cast-iron	$5\frac{1}{2}$ to $10\frac{1}{2}$	25 to 65	9 to 13	5000 to 6000	1300 to 2500
,, average	7	42	11		
,, American (ordnance)	14	36 to 58			
,, ,, strengthened by successive fusions	15 to 20	60 to 75			
Wrought iron—					
Finest Lowmoor and Yorkshire plates	27 to 29 along the fibre; 24 across the fibre		18 to 22, or about $\frac{4}{5}$ of f_t	12,000 to 13,000	5000
Staffordshire	26 along ,,; 24 across ,,				
Bridge iron	22 along ,,; 19 across ,,				
Bars, finest	27 to 29				
Ordinary good	25	20			
Soft Swedish	19 to 24				
Wrought-iron wire	25 to 50				
,, ,, average about	35				
Steel—					
Mild steel plates (Siemens or Bessemer)	26 to 32 average about 30		about $\frac{3}{4}$ of ft	12 000 to 13,000	5000 to 5200
Axle and rail steel (do)	30 to 45				
Crucible tool steel	40 to 65				
Steel castings	about 28				
Chrome steel	80				
Tungsten steel	72				
Whitworth's fluid compressed steel (mild)	40				
,, ,, (hard)	48 to 65

Graphic representation of distributed stress

53 Space admits of no more than a short and elementary account of some of the more simple straining actions that occur in machines and engineering structures

The stress which acts on any plane surface AB (fig 25), such as an imaginary cross section of a strained piece, may be represented by a figure formed by setting up ordinates Aa, Bb, &c, from points on the surface, the length of these being made proportional to the intensity of stress at each point This gives an ideal solid, which may be called the stress figure, whose height shows the distribution of stress over the surface which forms its base A line drawn from g, the centre of gravity of the stress figure, parallel to the ordinates Aa, &c, determines the point C, which is called the centre of stress, and is the point through which the resultant of the distributed stress acts In the case of a uniformly distributed stress, ab is a plane surface parallel to AB, and C is the centre of gravity of the surface AB When a bar is subjected to simple pull applied axially—that

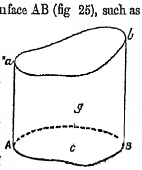

Fig 25

Centre of stress

is to say, so that the resultant stress passes through the centre of gravity of every cross section,—the stress may be taken as (sensibly) uniformly distributed over any section not near a place where the form of the cross section changes, provided the bar is initially in a state of ease and the stress is within the limits of elasticity

Uniformly varying stress

54 Uniformly varying stress is illustrated by fig 26 It occurs (in each case for stresses within the elastic limit) in a bent beam, in a tie subjected to non axial pull, and in a long strut or column where buckling makes the stress become non axial In uniformly varying stress the intensity p at any point P is proportional to the distance of P from a line MN, called the neutral axis, which lies in the plane of the stressed surface and at right angles to the direction AB, which is assumed to be that in which the intensity of stress varies most rapidly There is no variation of stress along lines parallel to MN If MN passes through C, the centre of gravity of the surface, as in fig 27, it may easily be shown that the total pull stress on one side of the neutral axis is equal to the total push stress on the other side, whatever be the form of the surface AB The resultant of the whole stress on AB is in that case a couple, whose moment may be found as follows Let dS be an indefinitely small part of the surface at a distance x from the neutral axis through C, and let p be the intensity of stress on dS The moment of the stress on dS is $xpdS$ But $p=p_1x/x_1=p_2x/x_2$ (see fig 27) The whole moment of the stress on AB is $\int xpdS=(p_1/x_1)\int x^2dS=p_1I/x_1$ or p_2I/x_2, where I is the moment of inertia of the surface AB about the neutral axis through C

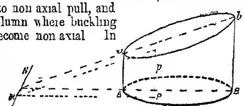

Fig 26

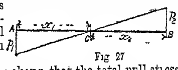

Fig 27

55 A stress such as that shown in fig 26 or fig 28 may be regarded as a uniformly distributed stress of intensity p_0 (which is the intensity at the centre of gravity of the surface C) and a stress of the kind shown in fig 27 The resultant is p_0S, where S is the whole area of the surface, and it acts at a distance CD from C such that the moment p_0S CD $=(p_2-p_0)I/x_1=(p_1+p_0)I/x_2$ Hence $p_2=p_0(1+x_2S\ CD/I)$, and $p_1=p_0(1-x_1S\ CD/I)$

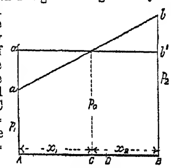

Fig 28

Simple bending

56 Simple bending occurs when a beam is in equilibrium under equal and opposite couples in the plane of the beam Thus if a beam (fig 29), supported at its ends, be loaded at two points so that $W_1l_1=W_2l_2$, the portion of the beam lying between W_1 and W_2 is subjected to a simple bending stress On any section AB the only stress consists of pull and push, and has for its resultant a couple whose moment $M=W_1l_1=W_2l_2$ This is called the *bending moment* at the section If the stress be within the elastic limits it will be distributed as in fig 30, with the neutral axis at the centre of gravity of the section The greatest intensities of push and of pull, at the top and bottom edge respectively, are (by § 54) $p_1=My_1/I$ and $p_2=My_2/I$, and the intensity at any point at a distance y above or below C is $p=My/I$

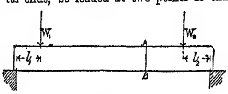

Fig 29

Fig 30

Bending beyond elastic limits

57 Let the bending moment now be increased, non elastic strain will begin as soon as either p_1 or p_2 exceeds the corresponding limit of elasticity, and the distribution of stress will be changed in consequence of the fact that the outer layers of the beam are taking set while the inner layers are still following Hooke's law As a simple instance we may consider the case of a material strictly elastic up to a certain stress, and then so plastic that a relatively very large amount of strain is produced without further change of stress, a case not very far from being realized by soft wrought-iron and mild steel The diagram of stress will now take the form sketched in fig 31 If the elastic limit is (say) less for compression than for tension, the diagram will be as in fig 32, with the neutral axis shifted towards the tension side When the beam is relieved from external load it will be left in a state of internal stress, represented, for the case of fig 31, by the dotted lines in that figure

58 In consequence of the action which has been illustrated (in a somewhat crude fashion) by figs 31 and 32, the moment required

[1] Stromeyer, "The Injurious Effect of a Blue Heat on Steel and Iron," *Min Proc Inst C E*, vol lxxxiv, 1886

to break the beam (M_1) cannot be calculated from the ultimate tensile or compressive strength of the material by using the formula $M_1=f_cI/y_1$, or $M_1=f_tI/y_2$. When experiments are made on the ultimate strength of bars to resist bending, it is not unusual to apply a formula of this form to calculate an imaginary stress f, which receives the name of the modulus of transverse rupture. Let the section be such that $y_1=y_2$. Then the modulus of transverse rupture is defined as $f=M_1y_1/I$.

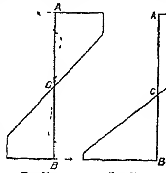

Fig 31 Fig 32

Modulus of rupture. This mode of stating the results of experiment on transverse strength is unsatisfactory, inasmuch as the modulus of rupture thus determined will vary with different forms of section. Thus a plastic material for which f_c and f_t are equal, if tested in the form of an I beam in which the flanges form practically the whole area of section, will have a modulus of rupture sensibly equal to f_t or f_c. On the other hand, if the material be tested in the form of a rectangular bar, the modulus of rupture may approach a value one and a half times as great. For in the latter case the distribution of stress may approach an ultimate condition in which half the section is in uniform tension f_t, and the other half in uniform compression of the same intensity. The moment of stress is then $\frac{1}{4}f_tbh^2$, b being the breadth and h the depth of the section, but by definition of the modulus of rupture f, $M=\frac{1}{6}fbh^2$. In tables of the modulus of transverse rupture the values are generally to be understood as referring to bars of rectangular section. Values of this modulus for some of the principal materials of engineering are given in the article BRIDGES, vol iv p 292.

Strain produced by bending. 59. The strain produced by bending stress in a bar or beam is, as regards any imaginary filament taken along the length of the piece, sensibly the same as if that filament were directly pulled or compressed by itself. The resulting deformation of the piece consists, in the first place and chiefly, of curvature in the direction of the length, due to the longitudinal extension and compression of the filaments, and, in the second place, of transverse flexure, due to the lateral compression and extension which go along with their longitudinal extension and compression (see ELASTICITY, § 57). Let l, fig 33, be a short portion of the length of a beam strained by a bending moment M (within the limits of elasticity). The beam, which we assume to be originally straight, bends in the direction of its length to a curve of radius R, such that $R/l=y_1/\delta l$, δl being the change of l by extension or compression, at a distance y_1 from the neutral axis. But $\delta l=lp_1/E$ by § 10, and $p_1=My_1/I$. Hence $R=EI/M$. The transverse flexure is not, in general, of practical importance. The centre of curvature for it is on the opposite side from the centre for longitudinal flexure, and the radius is $R\sigma$, where σ is the ratio of longitudinal extension to lateral contraction under simple pull.

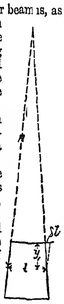

Fig 33

Ordinary bending of beams. 60. Bending combined with shearing is the mode of stress to which beams are ordinarily subject, the loads, or externally applied forces, being applied at right angles to the direction of the length. Let AB, fig 34, be any cross section of a beam in equilibrium. The portion V of the beam, which lies on one side of AB, is in equilibrium under the joint action of the external forces F_1, F_2, F_3, &c., and the forces which the other portion U exerts on V in consequence of the state of stress at AB. The forces F_1, F_2, F_3, &c may be referred to AB by introducing couples whose moments are F_1x_1, F_2x_2, F_3x_3, &c. Hence the stress at AB must equilibrate, first, a couple whose moment is ΣFx, and, second, a force whose value is ΣF, which tends to shear V from U. In these summations regard must of course be had to the sign of each force; in the diagram the sign of F_3 is opposite to the sign of F_1 and F_2. Thus the stress at AB may be regarded as that due to a bending moment M equal to the sum of the moments about the section of the externally applied forces on one side of the section (ΣFx), and a shearing force equal to the sum of the forces about one side of the section (ΣF). It is a matter of convenience only whether the forces on V or on U be taken in reckoning the bending moment and the shearing force. The bending moment causes a uniformly varying normal stress on AB of the kind already discussed in § 56; the shearing force causes a shearing stress in the plane of the section, the distribution of which will be investigated later. This shearing stress in the plane of the section is (by § 6) accompanied by an equal intensity of shearing stress in horizontal planes parallel to the length of the beam.

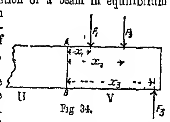

Fig 34.

61. The stress due to the bending moment, consisting of longitudinal push in filaments above the neutral axis and longitudinal pull in filaments below the neutral axis, is the thing chiefly to be considered in practical problems relating to the strength of beams. The general formula $p_1=My_1/I$ becomes, for a beam of rectangular section of breadth b and depth h, $p_1=6M/bh^2=6M/Sh$, S being the area of section. For a beam of circular section it becomes $p_1=32M/\pi h^3=8M/Sh$. The material of a beam is disposed to the greatest advantage as regards resistance to bending when the form is that of a pair of flanges or booms at top and bottom, held apart by a thin but stiff web or by cross bracing, as in I beams and braced trusses. In such cases sensibly the whole bending moment is taken by the flanges, the intensity of stress over the section of each flange is very nearly uniform, and the areas of section of the tension and compression flanges (S_1 and S_2 respectively) should be proportioned to the value of the ultimate strengths f_t and f_c, so that $S_1f_t=S_2f_c$. Thus for cast iron beams Hodgkinson has recommended that the tension flange should have six times the sectional area of the compression flange. The intensity of longitudinal stress on the two flanges of an I beam is approximately M/S_1h and M/S_2h, h being the depth from centre to centre of the flanges.

Diagrams of bending moment and shearing force. 62. In the examination of loaded beams it is convenient to represent graphically the bending moment and the shearing force at various sections by setting up ordinates to represent the values of these quantities. Curves of bending moment and shearing force for a number of important practical cases of beams supported at the ends will be found in the article BRIDGES, with expressions for the maximum bending moment and maximum shearing force under various distributions of load. The subject may be briefly illustrated

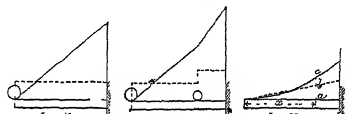

Fig 35 Fig 36 Fig 37

here by taking the case of a cantilever or projecting bracket—(1) loaded at the end only (fig 35), (2) loaded at the end and at another point (fig 36), (3) loaded over the whole length with a uniform load per foot run. Curves of bending moment are given in full lines and curves of shearing force in dotted lines in the diagrams.

The area enclosed by the curve of shearing force, up to any ordinate, such as ab (fig 37), is equal to the bending moment at the same section, represented by the ordinate ac. For let x be increased to $x+\delta x$, the bending moment changes to $\Sigma F(x+\delta x)$, or $\delta M=\delta x\Sigma F$. Hence the shearing force at any section is equal to the rate of change of the bending moment there per unit of the length, and the bending moment is the integral of the shearing force with respect to the length. In the case of a continuous distribution of load, it should be observed that, when x is increased to $x+\delta x$, the moment changes by an additional amount which depends on $(\delta x)^2$ and may therefore be neglected.

Distribution of shearing stress. 63. To examine the distribution of shearing stress over any vertical section of a beam, we may consider two closely adjacent sections AB and DE (fig 38), on which the bending moments are M and $M+\delta M$ respectively. The resultant horizontal force due to the bending stresses on a piece ADHG enclosed between the adjacent sections, and bounded by the horizontal plane GH at a distance y_0 from the neutral axis, is shown by the shaded figure. This must be equilibrated by the horizontal shearing stress on GH, which is the only other horizontal force acting on the piece. At any height y the intensity of resultant horizontal stress due to the difference of the bending moments is $y\delta M/I$, and the whole horizontal force on GH is $\frac{\delta M}{I}\int_{y_0}^{y_1} yzdy$, z being the breadth. If q be the intensity of horizontal shearing stress on the section GH, whose breadth is z_0, we have

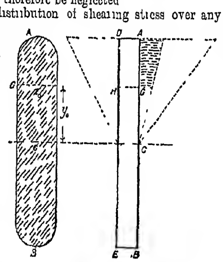

Fig 38

$$qz_0\delta x=\frac{\delta M}{I}\int_{y_0}^{y_1} yzdy$$

But $\delta M/\delta x$ is the whole shearing force Q on the section of the beam Hence

$$q=\frac{Q}{z_0 I}\int_{y_0}^{y_1} yz\,dy\,,$$

and this is also the intensity of vertical shearing stress at the distance y_0 from the neutral axis This expression may conveniently be written $q=QAy/z_0I$, where A is the area of the surface AG and y the distance of its centre of gravity from the neutral axis The intensity q is a maximum at the neutral axis and diminishes to zero at the top and bottom of the beam In a beam of rectangular section the value of the shearing stress at the neutral axis is $q_{max}=\frac{3}{2}Q/bh$ In other words, the maximum intensity of shearing stress on any section is $\frac{3}{2}$ of the mean intensity Similarly, in a beam of circular section the maximum is $\frac{4}{3}$ of the mean This result is of some importance in application to the pins of pin joints, which may be treated as very short beams liable to give way by shearing

In the case of an I beam with wide flanges and a thin web, the above expression shows that in any vertical section q is nearly constant in the web, and insignificantly small in the flanges Practically all the shearing stress is borne by the web, and its intensity is very nearly equal to Q divided by the area of section of the web

Principal stresses in a beam

64 The foregoing analysis of the stresses in a beam, which resolves them into longitudinal pull and push, due to bending moment, along with shear in longitudinal and transverse planes, is generally sufficient in the treatment of practical cases If, however, it is desired to find the direction and greatest intensity of stress at any point in a beam, the planes of principal stress passing through the point must be found by an application of the general method given in the article ELASTICITY, chapter iii In the present case the problem is exceptionally simple, from the fact that the stresses on two planes at right angles are known, and the stress on one of these planes is wholly tangential Let AC (fig 39) be an indefinitely small portion of the horizontal section of a beam, on which there is only shearing stress, and let AB be an indefinitely small portion of the vertical section at the same place, on which there is shearing and normal stress Let q be the intensity of the shearing stress, which is the same on AB and AC, and let p be the intensity of normal stress on AB it is required to find a third plane BC, such that the stress on it is wholly normal, and to find r, the intensity of that stress Let θ be the angle (to be determined) which BC makes with AB Then the equilibrium of the triangular wedge ABC requires that

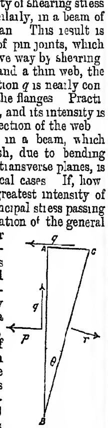

Fig 39

$$r\,BC\cos\theta=p\ AB+q\ AC,\ \text{and}\ r\,BC\sin\theta=q\ AB\,,$$

or $\quad (r-p)\cos\theta=q\sin\theta,\ \text{and}\ r\sin\theta=q\cos\theta$

Hence,

$$q^2=r(r-p),$$
$$\tan 2\theta=2q/p\,,$$
$$r=\tfrac{1}{2}p\pm\sqrt{q^2+\tfrac{1}{4}p^2}$$

The positive value of r is the greater principal stress, and is of the same sign as p The negative value is the lesser principal stress, which occurs on a plane at right angles to the former The equation for θ gives two values corresponding to the two planes of principal stress The greatest intensity of shearing stress occurs on the pair of planes inclined at 45° to the planes of principal stress, and its value is $\sqrt{q^2+\frac{1}{4}p^2}$ (by § 5)

65 The above determination of r, the greatest intensity of stress due to the combined effect of simple bending and shearing, is of some practical importance in the case of the web of an I beam We have seen that the web takes practically the whole shearing force, distributed over it with a nearly uniform intensity q If there were no normal stress on a vertical section of the web, the shearing stress q would give rise to two equal principal stresses, of pull and push, each equal to q, in directions inclined at 45° to the section But the web has further to suffer normal stress due to bending, the intensity of which at points near the flanges approximates to the intensity on the flanges themselves Hence in these regions the greater principal stress is increased, often by a considerable amount, which may easily be calculated from the foregoing formula What makes this specially important is the fact that one of the principal stresses is a stress of compression, which tends to make the web yield by buckling, and must be guarded against by a suitable stiffening of the web

The equation for θ allows the lines of principal stress in a beam to be drawn when the form of the beam and the distribution of loads are given An example has been shown in the article BRIDGES (§ 13, fig 12), vol iv p 290

Deflexion of beams

66 The deflexion of beams is due partly to the distortion caused by shearing, but chiefly to the simple bending which occurs at each vertical section As regards the second, which in most cases is the only important cause of deflexion, we have seen (§ 59) that the radius of curvature R at any section, due to a bending moment M, is EI/M, which may also be written Ey_1/p_1 Thus beams of uniform strength and depth (and, as a particular case, beams of uniform section subjected to a uniform bending moment) bend into a circular arc In other cases the form of the bent beam, and the resulting slope and deflexion, may be determined by integrating the curvature throughout the span, or by a graphic process (see BRIDGES, § 25), which consists in drawing a curve to represent the beam with its curvature greatly exaggerated, after the radius of curvature has been determined for a sufficient number of sections In all practical cases the curvature is so small that the arc and chord are of sensibly the same length Calling i the angle of slope, and u the dip or deflexion from the chord, the equation to the curve into which an originally straight beam bends may be written

$$\frac{du}{dx}=i,\ \frac{d^2u}{dx^2}=\frac{di}{dx}=\frac{EI}{M}$$

Integrating this for a beam of uniform section, of span L, supported at its ends and loaded with a weight W at the centre, we have, for the greatest slope and greatest deflexion, respectively, $i_1=WL^2/16EI$, $u_1=WL^3/48EI$ If the load W is uniformly distributed over L, $i_1=WL^2/24EI$ and $u_1=5WL^3/384EI$ For other cases, see BRIDGES, § 24

The additional slope which shearing stress produces in any originally horizontal layer is q/C, where q is, as before, the intensity of shearing stress and C is the modulus of rigidity In a round or rectangular bar the additional deflexion due to shearing is scarcely appreciable In an I beam, with a web only thick enough to resist shear, it may be a somewhat considerable proportion of the whole

Torsion hollow shafts

67 *Torsion* occurs in a bar to which equal and opposite couples are applied, the axis of the bar being the axis of the couples, and of solid gives rise to shearing stress in planes perpendicular to the axis and Let AB (fig 40) be a uniform circular shaft held fast at the end A, and twisted by a couple applied in the plane BB Assuming the strain to be within the limits of elasticity, a radius CD turns round to CD′, and a line AD drawn at any distance r from the axis,

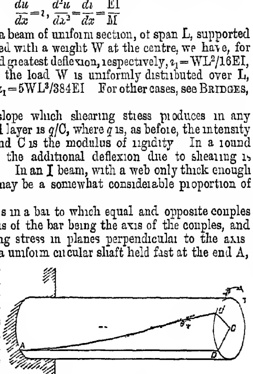

Fig 40

and originally straight, changes into the helix AD′ Let θ be the angle which this helix makes with lines parallel to the axis, or in other words the angle of shear at the distance r from the axis, and let i be the angle of twist DCD′ Taking two sections at a distance dx from one another, we have the arc $\theta dx=r\,di$ Hence q, the intensity of shearing stress in a plane of cross section, varies as r, since $q=C\theta=Cr\dfrac{di}{dx}$ The resultant moment of the whole shearing stress on each plane of cross-section is equal to the twisting moment M Thus

$$\int 2\pi r^2 q\,dr=M$$

Calling r_1 the outside radius (where the shearing stress is greatest) and q_1 its intensity there, we have $q=rq_1/r_1$, and hence, for a solid shaft, $q_1=2M/\pi r_1^3$ For a hollow shaft with a central hole of radius r_2 the same reasoning applies the limits of integration are now r_1 and r_2, and

$$q_1=\frac{2Mr_1}{\pi(r_1^4-r_2^4)}$$

The lines of principal stress are obviously helices inclined at 45° to the axis

If the shaft has any other form of section than a solid or symmetrical hollow circle, an originally straight radial line becomes warped when the shaft is twisted, and the shearing stress is no longer proportional to the distance from the axis The twisting of shafts of square, triangular, and other sections has been investigated by M de St Venant (see ELASTICITY, § 66–71, where a comparison of torsional rigidities is given) In a square shaft (side $=h$) the stress is greatest at the middle of each side, and its intensity there[1] is $q_1=M/0\ 281h^3$

For round sections the angle of twist per unit of length is

$$i=\frac{q_1}{Cr_1}=\frac{2M}{\pi Cr_1^4}\ \text{in solid and}\ \frac{2M}{\pi C(r_1^4-r_2^4)}\ \text{in hollow shafts}$$

68 In what has been said above it is assumed that the stress is within the limit of elasticity When the twisting couple is increased so that this limit is passed, plastic yielding begins in the outermost layer, and a larger proportion of the whole stress falls to be borne by layers nearer the centre The case is similar to that of a beam bent beyond the elastic limit, described in § 57 If we suppose the process of twisting to be continued, and that after passing the limit of elasticity the material is capable of much distortion without further increase of shearing stress, the distribution of stress on any cross section will finally have an approximately uniform value q', and the moment of torsion will be $\int_{r_2}^{r_1} 2\pi r^2 q'\,dr$ $=\frac{2}{3}\pi q'(r_1^3-r_2^3)$ In the case of a solid shaft this gives for M a

[1] Rankine, *Applied Mechanics*, § 324

value greater than it has when the stress in the outermost layer only reaches the intensity q', in the ratio of 4 to 3 [1] It is obvious from this consideration that the ultimate strength of a shaft to resist torsion is no more deducible from a knowledge of the ultimate shearing strength of the material than the ultimate strength of a beam to resist bending is deducible from a knowledge of f_t and f_c It should be noticed also that as regards ultimate strength a solid shaft has an important advantage over a hollow shaft of the same elastic strength, or a hollow shaft so proportioned that the greatest working intensity of stress is the same as in the solid shaft

69 *Twisting combined with Longitudinal Stress* —When a rod is twisted and pulled axially, or when a short block is twisted and compressed axially, the greatest intensity of stress (the greater principal stress) is to be found by compounding the longitudinal and shearing stresses as in § 64 In a circular rod of radius r_1, a total longitudinal force P in the direction of the axis gives a longitudinal normal stress whose intensity $p_1 = P/\pi r_1^2$ A twisting couple M applied to the same rod gives a shearing stress whose greatest intensity $q_1 = 2M/\pi r_1^3$ The two together give rise to a pair of principal stresses of intensities $r = P/2\pi r_1^2 \pm \sqrt{(2M/\pi r_1^3)^2 + (P/2\pi r_1^3)^2}$, their inclinations to the axis being defined by the equation $\tan 2\theta = 2M/r_1 P$, and the term under the square root is the greatest intensity of shearing stress

Torsion and bending of cranks

70 *Twisting combined with Bending* —This important practical case is realized in a crank-shaft (fig 41) Let a force P be applied at the crank pin A at right angles to the plane of the crank At any section of the shaft C (between the crank and the bearing) there is a twisting moment $M_1 = P$ AB, and a bending moment $M_2 = P$ BC There is also a direct shearing force P, but this does not require to be taken into account in calculating the stress at points at the top or bottom of the circumference (where the intensity is greatest), since (by § 68) the direct shearing stress is distributed so that its intensity is zero at these points The stress there is consequently made up of longitudinal normal stress (due to bending), $p_1 = 4M_2/\pi r_1^3$, and shearing stress (due to torsion), $q_1 = 2M_1/\pi r_1^3$ Combining these, as in § 64, we find for the principal stresses $r = 2(M_2 \pm \sqrt{M_1^2 + M_2^2})/\pi r_1^3$, or $r = 2P(BC \pm AC)/\pi r_1^3$ The greatest shearing stress is 2P $AC/\pi r_1^3$, and the axes of principal stress are inclined so that $\tan 2\theta = M_1/M_2 = AB/BC$ The axis of greater principal stress bisects the angle ACB

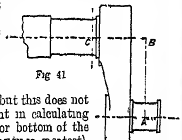

Fig 41

Strength of struts

71 *Long Columns and Struts—Compression and Bending* —A long strut or pillar, compressed by forces P applied at the ends in the direction of the axis, becomes unstable as regards flexure when P exceeds a certain value Under no circumstances can this value of P be exceeded in loading a strut But it may happen that the intensity of stress produced by smaller loads exceeds the safe compressive strength of the material, in which case a lower limit of load must be chosen If the applied load is not strictly axial, if the strut is not initially straight, if it is subject to any deflexion by transverse forces, or if the modulus of elasticity is not uniform over each cross section,—then loads smaller than the limit which causes instability will produce a certain deflexion which increases with increase of load, and will give rise to a uniformly varying stress of the kind illustrated in figs 26 and 28 We shall first consider the ideal case in which the forces at the ends are strictly axial, the strut perfectly straight and free from transverse loads and perfectly symmetrical as to elasticity Two conditions have to be distinguished—that in which the ends are left free to bend, and that in which the ends are held fixed In what follows, the ends are supposed free to bend The value of the load which causes instability will be found by considering what force P applied to each end would suffice to hold an originally straight strut in a bent state, supposing it to have received a small amount of elastic curvature in any way Using u as before to denote the deflexion at any part of the length, the bending moment is Pu, and (taking the origin at the middle of the chord) the equation to the elastic curve is

$$\frac{d^2u}{dx^2} = \frac{-Pu}{EI},$$

from which, for a strut of uniform section, $u = u_1 \cos x\sqrt{P/EI}$, u_1 being the deflexion at the centre, Now $u=0$ when $x = \frac{1}{2}L$ (the half length), and therefore $\frac{1}{2}L\sqrt{P/EI} = \frac{1}{2}\pi$ or an integral multiple of $\frac{1}{2}\pi$ The smallest value ($\frac{1}{2}\pi$) corresponds to the least force P Thus the force required to maintain the strut in its curved state is $P = \pi^2 EI/L^2$, and is independent of u_1 This means that with this particular value of P (which for brevity we shall write P_1) the strut will be in neutral equilibrium when bent, with a value of P less than P_1 it will be stable, with a greater value it will be unstable Hence a load exceeding P_1 will certainly cause rupture The value $\pi^2 EI/L^2$ applies to struts with round ends, or ends free to turn If the ends are fixed the effective length for bending is reduced by one half, so that P_1 then is $4\pi^2 EI/L^2$ When one end is fixed and the other is free P_1 has an intermediate value, probably about $9\pi^2 EI/4L^2$

72 The above theory, which is Euler's, assigns P_1 as a limit to the strength of a strut on account of flexural instability, but a stress less than P_1 may cause direct crushing Let S be the area of section, and f_c the strength of the material to resist crushing Thus a strut which conforms to the ideal conditions specified above will fail by simple crushing if f_cS is less than P_1, but by bending if f_cS is greater than P_1 Hence with a given material and form of section the ideal strut will fail by direct crushing if the length is less than a certain multiple of the least breadth (easily calculated from the expression for P_1), and in that case its strength will be independent of the length, when the length is greater than this the strut will yield by bending, and its strength diminishes rapidly as the length is increased

But the conditions which the above theory assumes are never realized in practice The load is never strictly axial, nor the strut absolutely straight to begin with, nor the elasticity uniform The result is that the strength is in all cases less than either f_cS or P_1 The effect of deviations from axiality, from straightness, and from uniformity of elasticity may be treated by introducing a term expressing an imaginary initial deflexion, and in this way Euler's theory may be so modified as to agree well with experimental results on the fracture of struts,[2] and may be reconciled with the observed fact that the deflexion of a strut begins gradually and passes through stable values before the stage of instability is reached In consequence of this stable deflexion the stress of compression on the inside edge becomes greater than P/S, the stress on the outside edge becomes less than P/S, and may even change into tension, and the strut may yield by one or the other of these stresses becoming greater than f_c or f_t respectively As regards the influence of length and moment of inertia of section on the deflexion of struts, analogy to the case of beams suggests that the greatest deflexion consistent with stability will vary as L^2/b, b being the least breadth, and the greatest and least stress, at opposite edges of the middle section, will consequently be

$$p_1 = \frac{P}{S}\left(1 \pm \frac{aL^2}{b^2}\right),$$

where a is a coefficient depending on the material and the form of the section This gives, for the breaking load, $P = Sf_c/(1 + aL^2/b^2)$ or $-Sf_t/(1 - aL^2/b^2)$, the smaller of the two being taken

This formula, which is generally known as Gordon's, can be made to agree fairly with the results of experiments on struts of ordinary proportions, when the values of f as well as a are treated as empirical constants to be determined by trial with struts of the same class as those to which the formula is to be applied Gordon's formula may also be arrived at in another way For very short struts we have seen that the breaking load is f_cS, and for very long struts it is $\pi^2 EI/L^2$ If we write $P = f_c S/(1 + f_c SL^2/\pi^2 EI)$, we have a formula which gives correct values in these two extreme cases, and intermediate values for struts of medium length By writing this $P = fS/(1 + cSL^2/I)$, and treating f and c as empirical constants, we have Gordon's formula in a slightly modified shape Gordon's formula is largely used, it is, however, essentially empirical, and it is only by adjustment of both constants that it can be brought into agreement with experimental results[3] For values of the constants, see BRIDGES In the case of fixed ends, c is to be divided by 4

Strength of shells to resist bursting

73 *Bursting Strength of Circular Cylinders and Spheres* —Space remains for the consideration of only one other mode of stress, of great importance from its occurrence in boilers, pipes, hydraulic and steam cylinders, and guns The material of a hollow cylinder, subjected to pressure from within, is thrown into a stress of circumferential pull When the thickness t is small compared with the radius R, we may treat this stress as uniformly distributed over the thickness Let p be the intensity of fluid pressure within a hollow circular cylinder, and let f be the intensity of circumferential stress Consider the forces on a small rectangular plate (fig 42), with its sides parallel and perpendicular to the direction of the axis, of length l and width R$\delta\theta$, $\delta\theta$ being the small angle it subtends at the axis Whatever forces act on this plate in the direction of the axis are equal and opposite The remaining forces, which are in equilibrium, are P, the total pressure from within, and a force T at each side due to the circumferential stress $P = plR\delta\theta$

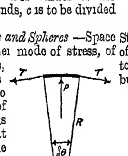

Fig 42

[1] See ELASTICITY, §§ 10-20

[2] See papers by Profs Ayrton and Perry, *The Engineer*, Dec 10 and 24, 1886, and by T C Fidler, *Min Proc Inst C E*, vol lxxxii p 261

[3] For experiments on the breaking strength of struts, see papers by Hodgkinson, *Phil Trans*, 1840, Berkeley, *Min Proc Inst C E*, vol xxx, Christie, *Trans Amer Soc. Civ Eng*, 1884

and $T = ft$ But by the triangle of forces (fig 43) $P = T\delta\theta$ Hence $f = pR/t$

The ends of the cylinder may or may not be held together by longitudinal stress in the cylinder sides, if they are, then, whatever be the form of the ends, a transverse section, the area of which is $2\pi Rt$, has to bear a total force $p\pi R^2$ Hence, if f' be the intensity of longitudinal stress, $f' = pR/2t = \frac{1}{2}f$

Fig 43

74 A thin hollow sphere under internal pressure has equal circumferential pull in all directions To find its value consider the plate of fig 42 There are now four equal forces T, on each of the four sides, to equilibrate the radial force P Hence $P = 2T\delta\theta$ and $f = pR/2t$

Thick cylinder 75 When the thickness is not small compared with the radius, the radial pressure is transmitted from layer to layer with reduced intensity, and the circumferential pull diminishes towards the outside In the case of a thick cylinder with free ends[1] we have to deal at any point with two principal stresses, radial and circumferential, which may be denoted by p and p' respectively Supposing (as we may properly do in dealing with a cylinder which is not very short) that a transverse section originally plane remains plane, the longitudinal strain is uniform Since there is no longitudinal stress this strain is due entirely to the lateral action of the stresses p and p', and its amount is $(p+p')/\sigma E$ Hence at all points $p + p' = \text{constant}$[2] Further, by considering the equilibrium of any thin layer, as we have already considered that of a thin cylinder, we have $\frac{d}{dr}(pr) = p'$

These two equations give by integration, $p = C + C'/r^2$, and $p' = C - C'/r^2$

If r_1 be the external and r_2 the internal radius, and p_0 the pressure on the inner surface, the conditions that $p = p_0$ when $r = r_2$ and $p = 0$ when $r = r_1$ give $C = -p_0r_2^2/(r_1^2 - r_2^2)$ and $C' = -Cr_1^2$ Hence the circumferential stress at any radius r is $p' = -p_0r_2^2(1 + r_1^2/r^2)/(r_1^2 - r_2^2)$ At the inside, where this is greatest, its value is $-p_0(r_1^2 + r_2^2)/(r_1^2 - r_2^2)$,—a quantity always greater than p_0, however thick the cylinder is

In the construction of guns various devices have been used to equalize the circumferential tension With cast guns a chilled core has been employed to make the inner layers solidify and cool first, so that they are afterwards compressed by the later contraction of the outer layers In guns built up of wrought iron or steel hoops the hoops are bored small by a regulated amount and are shrunk on over the barrel or over the inner hoops In Mr Longridge's system, now under trial, the gun is made by winding steel wire or ribbon, with suitable initial tension, on a central barrel

76 The circumferential stress at any point of a thick hollow sphere exposed to internal fluid pressure is found, by a process like that of the last paragraph, to be $-p_0r_2^3(1 + r_1^3/2r^3)/(r_1^3 - r_2^3)$, which gives, for the greatest tension, the value

$$-p_0(r_1^3 + 2r_2^3)/2(r_1^3 - r_2^3)$$

(J A E)

[1] This condition is realized in practice when the fluid causing internal pressure is held in by a piston, and the stress between this piston and the other end of the cylinder is taken by some other part of the structure than the cylinder sides

[2] The solution which follows in the text is applicable even when there is longitudinal stress, provided that the longitudinal stress is uniformly distributed over each transverse section If we call this stress p'', the longitudinal strain is $p''/E + (p+p')/\sigma E$ Since the whole strain is uniform, and p'' is uniform, the sum of p and p' is constant at all points, as in the case where the ends are free

---

STRICKLAND, Agnes (1806-1874), a popular historical writer, was born in 1806, the third daughter of Thomas Strickland, of Roydon Hall, Suffolk Her first literary efforts were historical romances in verse in the style of Walter Scott,—*Worcester Field* (published without date), *Demetrius and other Poems* (1833) From this she passed to prose histories, written in a simple style for the young A picturesque sketch of the *Pilgrims of Walsingham* appeared in 1835, two volumes of *Tales and Stories from History* in the following year Then with the assistance of her sister she projected a more ambitious work, *The Lives of the Queens of England*, from Mathilda of Flanders to Queen Anne The first volume appeared in 1840, the twelfth and last in 1849 Miss Strickland was a warm partisan on the side of royalty and the church, but she made industrious study of "official records and other public documents," gave copious extracts from them, and drew interesting pictures of manners and customs While engaged on this work she found time to edit (in 1843) the *Letters of Mary, Queen of Scots*, whose innocence she championed with enthusiasm In 1850 she followed up her *Queens of England* with the *Lives of the Queens of Scotland*, completing the series in eight volumes in 1859 Unresting in her industry, she turned next to the *Batchelor Kings of England*, about whom she published a volume in 1861 The *Lives of the Seven Bishops* followed in 1866—after a longer interval, part of which was employed in producing an abridged version of her *Queens of England* Her last work was the *Lives of the Last Four Stuart Princesses*, published in 1872 In 1871 she obtained a civil list pension of £100 in recognition of her merits She died at Roydon Hall on the 8th of July 1874

A *Life* by her sister, Jane Margaret Strickland, appeared in 1887

STRIEGAU, an industrial town of Prussia, in the province of Silesia, is situated on a small tributary of the Weistritz, 30 miles to the south-west of Breslau In 1880 it contained 11,470 inhabitants, 6928 of whom were Protestants and 4379 Roman Catholics Their chief occupations are tanning and the manufacture of albums, portfolios, and other articles in leather Granite is quarried in the neighbourhood, and a trade is carried on in grain It was near Striegau that Frederick the Great gained the important victory usually named after the village of Hohenfriedberg (June 4, 1745)

STROMBOLI See Lipari Islands

STRONTIUM, a metallic chemical element intermediate in its character between barium and calcium, with which it forms a natural "triad" Though widely diffused as a frequent companion of calcium (including oceanic), it occurs nowhere in abundance Its most important mineral forms are the sulphate, $SrSO_4$, known as *Cœlestine* (from the sky-blue colour of certain varieties), and the carbonate, $SrCO_3$, called *Strontianite* because it was discovered first at Strontian, in Argyllshire, Scotland Crawford and (independently of him) Cruickshanks in 1790 were the first to recognize the latter mineral as a thing of its own kind and different from witherite ($BaCO_3$) Hope, in 1793, proved it to be the carbonate of a new earth, which discovery was confirmed by Klaproth

Regarding metallic strontium, see Chemistry, vol v pp 525-6 For the making of strontium preparations strontianite, of course, is the handier raw material, being readily convertible into (for instance) nitrate by treatment with dilute nitric acid From the nitrate the oxide, SrO, is obtained by prolonged calcination at ultimately a bright red heat, as a greyish white absolutely infusible and non-volatile mass, which acts violently on water with formation of the hydrate, $Sr(OH)_2$, which latter readily takes up $8H_2O$ of water to form crystals soluble in fifty parts of cold and far less of boiling water An impure oxide is obtainable directly from strontianite by strong ignition with charcoal, and from such crude oxide pure crystals of the hydrate are easily produced by obvious operations

In the working up of cœlestine the first step is to reduce it to sulphide, SrS, by means of charcoal at a red heat The sulphide when boiled with water is decomposed thus —

$$2SrS + 2H_2O = SrOH_2O + SrSH_2S$$

Hydrate Sulphydrate

Both products dissolve in the hot water, from the solution the S of the SrH_2S_2 is easily eliminated, by treatment with oxide of copper or oxide of zinc, as insoluble metallic sulphide, the filtrate on cooling gives crystals of pure hydrate From it any strontia salt of course is easily made by means of the respective acid, in many cases the salt wished for can be obtained similarly from the sulphide.

Nitrate of strontia from hot solutions crystallizes in anhydrous octahedra, SrN_2O_6, soluble in about $\frac{1}{2}$ part of boiling and in 5 parts of cold water From colder solutions hydrated crystals, $SrN_2O_6 + 4H_2O$, separate out The anhydrous salt is used largely by pyrotechnists for the making of "red fire"

The hydroxide some years ago promised to play an important part in the sugar industry as a precipitant for the cane-sugar known to be present largely in uncrystallizable molasses (see Sugar), but the process so far has failed to take root in industry.

Analysis—To detect strontium in a salt-solution, we first eliminate the heavy metals by the successive application of sulphuretted hydrogen (and free acid) and of sulphide of ammonium in the presence of ammonia and sal ammoniac From the filtrate carbonate of ammonia (in the heat) precipitates only the barium, strontium, and calcium as carbonates, which are filtered off and washed with hot water The analysis of the precipitate is difficult, but any strontia in it is easily detected by means of the spectroscope (see SPECTROSCOPY)

STROPHANTHUS, a genus of plants of the natural order *Apocyneæ*, deriving its name from the long twisted thread-like segments of the corolla, which in one species attain a length of 12 or 14 inches The genus at present comprises about 18 species, confined to tropical Africa and Asia, only one species, indigenous to the former continent, being known outside the tropics Several of the African species furnish the natives of the countries in which they grow with the principal ingredient in their arrow poisons The inee or onaye poison of the Gaboon, the kombé poison of equatorial North Africa, the arquah poison of the banks of the Niger, and the wanika poison of Zanzibar are all derived from members of this genus The exact species used in each case cannot be said to be accurately known There is little doubt, however, that *S hispidus*, D C, is the one most frequently employed

Two of the arrow poisons have been chemically and physiologically examined The kombé poison was subjected to some preliminary experiments in 1862 by Prof Sharpey, but was more fully examined a few years subsequently by Prof T R Fraser From the investigations of the latter[1] it appears that the kombé arrow poison, when given in fatal doses, paralyses the action of the heart In minute doses, however, it possesses a tonic action on that organ Since the practical value of strophanthus as a medicinal agent has been pointed out by Prof Fraser, it has been used with considerable success in some forms of heart-disease The chemical examination showed that its activity is due to a glucoside, which has been named strophanthin The wanika arrow poison has been examined physiologically by Dr Sydney Ringer and chemically by Mr A W Gerrard Its active principle, a glucoside, was found to resemble strophanthin in its action Chemically also, as obtained by Mr Gerrard, it seems to be identical with strophanthin[2] It is soluble in alcohol and water, but insoluble in ether and chloroform, it evolves ammonia when heated with soda-lime, but gives only a slight brown coloration when treated with strong sulphuric acid

Both *S hispidus* and *S Kombe* have hairy seeds with a slender thread-like appendage, terminating in a feathery tuft of long silky hairs, the seeds of the former being coated with short appressed brown hairs, and those of the latter with white hairs, but in the species used at Delagoa Bay and called "umtsuli" the thread like appendage of the seed is absent According to information furnished by Messrs T Christy & Company of London, and obtained from a correspondent on the Zanzibar coast, the natives pound the seeds into an oily mass, which assumes a red colour, portions of this mass being smeared on the arrow immediately behind the barb

See *Icones Plantarum*, No 4, 1870, Pelikan, *Arch Gen de Médecine*, July 1865, p 115, Van Hasselt, *Arch Neerl des Sc*, [2], vii, 1872, p 161, *Arch de Physiol*, No 5, 1872, p 526, *Rapport sur l'Inaye*, Paris, 1877, 8vo

STROUD, a market-town of Gloucestershire, is situated on the Swindon and Gloucester branch of the Great Western Railway, on a branch of the Midland Railway, and on the Thames and Severn Junction Canal, 10 miles south of Gloucester and 30 north-east of Bristol It is picturesquely situated on an eminence environed by higher hills, but is built in a somewhat straggling and irregular fashion Among the principal buildings are the town-hall, built in the reign of Elizabeth, the Lansdown hall (1879), the Badbrook hall (1869), with reading-room and large room for concerts, the subscription rooms (1834), and the hospital, erected in 1875 at a cost of £8754, to replace the dispensary erected in 1823 The town is the principal seat of the west of England cloth manufacture, and possesses very extensive mills There are also silk mills, scarlet-dye works, breweries, logwood-crushing mills, and flour mills Stroud at the time of the Norman survey was part of Bisley parish, from which it was separated in 1304 The local board was established in 1857 The population of the urban sanitary district (area 999 acres) in 1871 was 7082, and in 1881 it was 7848

STRUENSEE, JOHANN FRIEDRICH, COUNT (1737–1772), Danish statesman, was of German extraction, and was born August 5, 1737, at Halle, where his father Adam Struensee, of some eminence as a hymn writer, was pastor He graduated M D at Halle in 1756, and obtained the office of physician to the town of Altona through the influence of his father, who had removed thither On account, however, of a change in his religious views he quarrelled with his father, and for some time he led an unsettled life, until in 1768 he was appointed personal physician to the young king, Christian VII of Denmark, whom he accompanied on a tour through England, France, Holland, and Germany The influence he exercised over the almost imbecile king awakened at first the jealousy of the queen, Caroline Matilda, a daughter of George II, but, having had occasion to attend her for a severe malady, he won her complete confidence also, and became equally the favourite of both When therefore in 1770 he was appointed master of requests, he virtually took the government of the kingdom into his own hands, and on the 20th September the council of state was superseded Though acting as an absolutist, his sympathies were democratic, and he used his position to promote the general benefit of the people and to curb the influence of the nobility The extent of his reforms, and the suddenness with which they were introduced, had all the practical effect of a revolution They included the enfranchisement of the peasants, complete religious toleration, the abolition of commercial restrictions, the reorganization of the army, and the introduction of examinations for public offices His reforms were received with consternation, and a conspiracy was entered into to effect his overthrow The queen dowager persuaded Christian VII that Struensee was carrying on an intrigue with the queen, and had entered into a plot to assassinate him, in order that he might rule as regent He and his friend Count Brandt were consequently arrested on 20th February 1772 The attempt to prove that he had been unfaithful in his duty as minister to the king failed, but he did not deny the *liaison* with the queen, and he and Count Brandt were both beheaded and quartered on the 28th April (see DENMARK, vol vii p 87)[3]

STRUVE, FRIEDRICH GEORG WILHELM (1793–1864), astronomer, was born at Altona on April 15, 1793 In 1808 he entered the university of Dorpat, where he first studied philology, but soon turned his attention to astronomy In 1813 he was appointed observer in the new university observatory and a few years later professor of astronomy He remained in Dorpat, occupied with researches on double stars and in geodetic work, till 1839, when he removed to Pulkova, near St Petersburg, as director of the new Central Observatory Here he continued his activity until he was obliged to retire (in 1861) owing to failing health He died at St Petersburg on November 23, 1864

[2] *Pharm Jour*, [3], xi pp 834, 835

[3] Carl Gustav Struensee von Carlsbach, elder brother of Johann Friedrich, born at Halle 18th August 1735, attained high eminence in the service of Prussia He was ennobled in 1789, became minister of finance and president of the excise department in 1791, and died at Berlin 17th October 1804

Struve's name is best known by his observations of double stars, which he carried on for many years. These bodies had first been regularly measured by W. Herschel, who discovered that many of them formed systems of two stars revolving round their common centre of gravity. After him J. Herschel (and for some time South) had observed them, but their labours were eclipsed by the systematic and more extensive ones of Struve. With the 9½-inch refractor at Dorpat he discovered a great number of double stars, and published in 1827 a list of all the known objects of this kind (*Catalogus Novus Stellarum Duplicium*). His micrometric measurements of 2714 double stars were made from 1824 to 1837, and are contained in his principal work *Stellarum Duplicium et Multiplicium Mensuræ Micrometricæ* (St Petersburg, 1837, fol.; a convenient summary of the results is given in vol. i. of the *Dunecht Observatory Publications*, 1876). The places of the objects were at the same time determined with the Dorpat meridian circle (*Stellarum Fixarum Imprimis Duplicium et Multiplicium Positiones Mediæ*, St Petersburg, 1852, fol.). At Pulkova he determined anew the constant of aberration, but was chiefly occupied in working out the results of former years' work and in the completion of the geodetic operations in which he had been engaged during the greater part of his life. He had commenced them with a survey of Livonia (1816–19), which was followed by the measurement of an arc of meridian of more than 3½° in the Baltic provinces of Russia (*Beschreibung der Breitengradmessung in den Ostseeprovinzen Russlands*, 2 vols. 4to, Dorpat, 1831). This work was afterwards extended by Struve and General Tenner into a measurement of a meridional arc from the north coast of Norway to Ismail on the Danube (*Arc du Méridien de 25° 20' entre le Danube et la Mer Glaciale*, 2 vols. and 1 vol. plates, St Petersburg, 1857–60, 4to).

STRY, or STRYJ, a town of Galicia, Austria, is pleasantly situated on a tributary of the Dniester, about 40 miles to the south of Lemberg. In 1880 it contained 12,625 inhabitants, chiefly engaged in tanning and the manufacture of matches. In 1886, however, the town was almost wholly destroyed by fire, and its population was greatly reduced by the wholesale migration and deaths from privation consequent upon this calamity.

STRYCHNINE. See POISONS, vol. xix. p. 279, and NUX VOMICA, vol. xvii. p. 687.

STRYPE, JOHN (1643–1737), historian and biographer, was the son of John Strype or Van Stryp, a native of Brabant, who to escape religious persecution went to England, and settled near London, in a locality afterwards known as Strype's Yard, formerly in the parish of Stepney, but subsequently annexed to that of Christ Church, Spitalfields. Here he carried on the business of a merchant and silk throwster. The son was born 1st November 1643. He was educated at St Paul's School, and on 5th July 1662 entered Jesus College, Cambridge. Thence he proceeded to Catherine Hall, where he graduated B.A. in 1665 and M.A. in 1669. On the 14th July of the latter year he was preferred to the curacy of Theydon-Bois, Essex, and a few months afterwards was chosen curate and lecturer of Low Leyton in the same county. On account of the smallness of the salary, the patron allowed the people to choose their own minister, the vacancy in the vicarage remaining unfilled during the life of Strype. He was never instituted or inducted, but in 1674 he was licensed by the bishop of London to preach and expound the word of God, and to perform the full office of priest and curate during the vacancy of the vicarage. In his later years he obtained from Archbishop Tenison the sinecure of Tarring, Sussex, and he discharged the duties of lecturer at Hackney till 1724. When he became infirm he took up his residence with Mr Harris, an apothecary at Hackney, who had married his daughter, and died there 11th December 1737, at the advanced age of ninety-four.

At an early period of his life Strype obtained access to the papers of Sir Michael Hicks, secretary to Lord Burghley, from which he made extensive transcripts; he also carried on an extensive correspondence with Archbishop Wake and Bishops Burnet, Atterbury, and Nicholson. The materials thus obtained formed the basis of his historical and biographical works, which relate chiefly to the period of the Reformation. The greater portion of his original materials have been preserved, and are included in the Lansdowne manuscripts in the British Museum. His works can scarcely be entitled original compositions, his labour having consisted chiefly in the arrangement of his materials; but on this very account they are of considerable value as convenient books of reference, easier of access and almost as trustworthy as the original documents. Besides a number of single sermons published at various periods, he was the author of an edition of Lightfoot's *Works*, vol. ii., 1684; *Memorials of Archbishop Cranmer*, 1694; *Life of Sir Thomas Smith*, 1698; *Life and Actions of John Aylmer, Bishop of London*, 1701; *Life of Sir John Cheke, with his Treatise on Superstition*, 1705; *Annals of the Reformation in England*, 4 vols., vol. i. 1709 (reprinted 1725), vol. ii. 1725, vol. iii. 1728, vol. iv. 1731, 2d ed. 1735, 4 vols., 3d ed. 1736–38, 4 vols.; *Life and Actions of Edmund Grindal, Archbishop of Canterbury*, 1710; *of Matthew Parker, Archbishop of Canterbury*, 1711; and *of John Whitgift, Archbishop of Canterbury*, 1818; *An Accurate Edition of Stow's Survey of London*, 1720, 2 vols. fol., the standard edition of Stow and of great value, although its interference with the original text is a method of editing which can scarcely be reckoned fair to the original author; and *Ecclesiastical Memorials*, 1721, 3 vols., 1733, 3 vols., new ed. 1816. His *Historical and Biographical Works* were published in 10 vols., with a general index, 1820–40.

STUART, STEWART, or STEUART, the surname of a family who became heirs to the Scottish and ultimately to the English crown. Their descent is traced to a Norman baron Alan, whose eldest son William became progenitor of the earls of Arundel, and whose two younger sons Walter and Simon came to Scotland, Walter being appointed high steward of David I., who conferred on him various lands in Renfrewshire, including Paisley, where he founded the abbey in 1160. Walter, his grandson, third steward, was appointed by Alexander II. justiciary of Scotland, and, dying in 1246, left four sons and three daughters. The third son Walter obtained by marriage the earldom of Menteith, which ultimately came by marriage to Robert, duke of Albany, third son of Robert II. Alexander, fourth steward, the eldest son of Walter, third steward, inherited by his marriage with Jean, granddaughter of Somerled, the islands of Bute and Arran, and on 2d October 1263 defeated Haco at Largs. He had two sons, James and John. The latter, who commanded the men of Bute at the battle of Falkirk in 1298, had seven sons:—(1) Sir Alexander, whose grandson became in 1389 earl of Angus, the title afterwards passing in the female line to the Douglases, and in 1761 to the duke of Hamilton; (2) Sir Alan of Dreghorn, ancestor of the earls and dukes of Lennox, from whom Lord Darnley, husband of Queen Mary, and also Arabella Stuart, were descended; (3) Sir Walter, who obtained the barony of Garlies, Wigtownshire, from his uncle John Randolph, earl of Moray, and was the ancestor of the earls of Galloway, younger branches of the family being the Stewarts of Tonderghie, Wigtownshire, and also those of Physgill and Glenturk in the same county; (4) Sir James, who fell at Dupplin in 1332, ancestor of the lords of Lorn, on whose descendants were conferred at different periods the earldoms of Athole, Buchan, and Traquair, and who were also the progenitors of the Stewarts of Appin, Argyllshire, and of Grandtully, Perthshire; (5) Sir John, killed at Halidon Hill in 1333; (6) Sir Hugh, who fought under Edward Bruce in Ireland; and (7) Sir Robert of Daldowie, ancestor of the Stewarts of Allanton and of Coltness. James Stewart, the eldest son of Alexander, fourth steward, succeeded his father in 1283, and, after distinguishing himself in the wars of Wallace and of Bruce, died in 1309. His son Walter, sixth steward, who had joint command with Douglas of the left wing at the battle of Bannockburn, married Marjory, daughter of Robert the Bruce, and during the latter's absence in Ireland was entrusted with the government of the kingdom. He died in 1326, leaving an only son, who as Robert II. ascended the throne of Scotland in 1370 (see vol. xxi. p. 490). Sir Alexander Stewart, earl of Buchan, fourth son of

Robert II, who earned by his ferocity the title of the "Wolf of Badenoch," inherited by his wife the earldom of Ross, but died without legitimate issue, although from his illegitimate offspring were descended the Stewarts of Belladrum, of Athole, of Garth, of Urrard, and of St Fort On the death of the "Wolf of Badenoch" the earldom of Buchan passed to his brother Robert, duke of Albany, also earl of Fife and earl of Menteith, but these earldoms were forfeited on the execution of his son Murdoch in 1425, the earldom of Buchan again, however, coming to the house of Stewart in the person of James, second son of Sir James Stewart, the black knight of Lorn, by Johanna, widow of King James I From Murdoch, duke of Albany, were descended the Stewarts of Ardvoirlich and other families of the name in Perthshire, and also the Stuarts of Inchbreck and Laithers, Aberdeenshire From a natural son of Robert II were descended the Steuarts of Dalguise, Perthshire, and from a natural son of Robert III the Shaw Stewarts of Blackhall and Greenock The direct male line of the royal family terminated with the death of James V in 1542, whose daughter Mary was the first to adopt the spelling "Stuart" Mary was succeeded in her lifetime in 1567 by her only son James VI, who through his father Lord Darnley was also head of the second branch, there being no surviving male issue of the family from progenitors later than Robert II In James V, son of James IV by Margaret, daughter of Henry VII, the claims of the English junior branch became merged in the Scottish line, and on the death of Queen Elizabeth of England, last surviving offshoot of Henry VIII, James VI of Scotland, lineally the nearest heir, was proclaimed king of England, in accordance with a declaration of Elizabeth that no minor person should ascend the throne, but her cousin the king of Scots The accession of James was, however, contrary to the will of Henry VIII, which favoured the Suffolk branch, whose succession would probably have marvellously altered the complexion of both Scottish and English history As it was, the only result of that will was a tragedy initiated by Elizabeth, but consummated by James, so as to clothe his memory with deep disgrace In the Scottish line the nearest heir after James VI, both to the Scottish and English crowns, was Arabella Stuart, only child of Charles, earl of Lennox, younger brother of Lord Darnley,—Lady Margaret Douglas, the mother of Darnley and his brother, having been the daughter of Archibald, sixth earl of Angus by Margaret, queen dowager of James IV James VI (I of England) was thus nearest heir of the junior English branch by a double descent, Arabella Stuart being next heir by a single descent On account of the descent from Henry VII, the jealousy of Elizabeth had already caused her to imprison Arabella's mother (Elizabeth, daughter of Sir William Cavendish) on learning that she had presumed to marry Lennox The daughter's marriage she was determined by every possible means to prevent She objected when King James proposed to marry her to Lord Esme Stuart, whom he had created duke of Lennox, but when the appalling news reached her that Arabella had actually found a lover in William Seymour, grandson of Catherine Grey, heiress of the Suffolk branch, she was so deeply alarmed and indignant that she immediately ordered her imprisonment This happened immediately before Elizabeth's death, after which she obtained her release Soon after the accession of James a conspiracy, of which she was altogether ignorant, was entered into to advance her to the throne, but this caused no alteration in her treatment by James, who allowed her a maintenance of £800 a year In February 1610 it was discovered that she was engaged to Seymour, and, although she then promised never to marry him without the king's consent, the marriage took place secretly in July following In consequence of this her husband was sent to the Tower, and she was placed in private confinement Though separated, both succeeded in escaping simultaneously on 3d June 1611, but, less fortunate than her husband, who got safe to the Continent, she was captured at the Straits of Dover, and shut up in the Tower Her hopeless captivity deprived her of her reason before her sorrows were ended by death, 27th September 1615

By the usurpation of Cromwell the Stuarts were excluded from the throne from the defeat of Charles I at Naseby in 1645 until the restoration of his son Charles II in 1661 Carlyle refers to the opinion of genealogists that Cromwell "was indubitably either the ninth or the tenth or some other fractional part of half a cousin of Charles Stuart," but this has been completely exploded by Walter Rye, in the *Genealogist* ("The Steward Genealogy and Cromwell's Royal Descent," new ser, vol ii pp 34–42) On the death of Charles II without issue in 1685, his brother James, duke of York, ascended the throne as James II, but he so alienated the sympathies of the nation by his unconstitutional efforts to further the Catholic religion that an invitation was sent to the prince of Orange to come "to the rescue of the laws and religion of England" Next to the son of James II, still an infant under his father's control, Mary, princess of Orange, eldest daughter of James II, had the strongest claim to the crown, but neither were the claims of the prince, even apart from his marriage, very remote, since he was the son of Mary, eldest daughter of Charles I The marriage had strengthened the claims of both, and they were proclaimed joint sovereigns of England on 12th February 1689, Scotland following the example of England on the 11th April They had no issue, and the Act of Settlement passed in 1701, excluding Catholics from the throne, secured the succession to Anne, second daughter of James II, and on her death without issue to the Protestant House of Hanover, descended from the princess Elizabeth, daughter of James I, wife of Frederick, count palatine of the Rhine On the death of Anne in 1714, George, elector of Hanover, eldest son of Sophia, electress of Hanover (only surviving child of the princess Elizabeth), and Ernest, youngest son of George, duke of Brunswick, consequently became sovereign of Great Britain and Ireland, and, notwithstanding somewhat formidable attempts in behalf of the elder Stuart line in 1715 and 1745, the Hanoverian succession has remained uninterrupted, and has ultimately won universal assent The female line of James II ended with the death of his daughter, Queen Anne James, called James III by the Jacobites and the Old Pretender by the Hanoverians, had two sons,—Charles Edward, the Young Pretender, who died without legitimate issue in 1780, and Henry, titular duke of York, commonly called Cardinal York, at whose death in 1807 the male line of James II came to an end He was also the last lineal male representative of any of the crowned heads of the race, so far as either England or Scotland was concerned, and excepting of course the Hanoverian line In the female Stuart line there are, however, still nearer heirs to the throne than those of the Hanoverian line, viz, the descendants of Henrietta, duchess of Orleans, daughter of Charles I, represented now only in Maria Theresa, married to Prince Louis Leopold of Bavaria, and their nine children The male representation of the family, being extinct in the royal lines, is claimed by the earls of Galloway and also by the Stewarts of Castlemilk, but the claims of both are more than doubtful

STUART, GILBERT (1755–1828), a distinguished American portrait-painter, was born in Narragansett, Rhode Island, U S, December 3, 1755 His father, a native of Perth, Scotland, and the son of a Presbyterian minister, had set up a snuff-mill in Narragansett, in company with another Scotsman, Dr Thomas Moffatt, and was known as "the snuff-grinder" The father removed early to Newport, where his son had the advantage of good instruction He began to draw early, but none of his sketches have been preserved His first known pictures are of two Spanish dogs, and two portraits, the latter painted when he was thirteen years old, and now in the Redwood Library, Newport In 1770–71 he received some instruction from a Scottish artist named Cosmo Alexander, who took him to Scotland with him, but, this patron dying soon after his arrival, Stuart, after struggling for a while at the university of Glasgow, had to work his way home in a collier In the spring of 1775 he sailed again for England, and became the pupil and assistant of Benjamin West, with whom he painted until 1785, when he set up a studio of his own One of his best pictures of this period is a full-length portrait of W Grant of Congalton skating in St James's Park, now at Moor Court, Stroud, in the possession of Lord Charles Pelham Clinton Two fine half-lengths by Stuart are in the National Gallery—his preceptor Benjamin West and the engraver Woolett Stuart married in London and remained there, with the exception of a short visit to Dublin in 1788, until 1792, when he returned to America Early in 1795 Stuart painted his first head of Washington This portrait exhibits the right side of the face, and, although the least familiar, is undoubtedly the truest of the three portraits of Washington from his hand The second was a full-length for the marquis of Lansdowne, and the third a vignette head now belonging to the Athenæum in Boston, U S These last two show the left side of the face, and, although they are the readily recognized "Stuart's Washington," are unsatisfactory as portraits and inferior as works of art There are sixty-one replicas of these three pictures, and they have been engraved more than two hundred times In the catalogue of Stuart's works are recorded seven hundred and fifty-four portraits Stuart remained in Philadelphia, where he painted many of the prominent men of the country, until 1803, when he removed to Washington, two years later he went to Boston, where he died July 27, 1828

Stuart's pictures have been little injured by time, which is doubtless owing to his use of pure colours and to his manner of employing them His practice was to lay all the tints in their places separately and distinctly alongside of each other before any blending was used, and then they were united by means of a large soft brush and without corrupting their freshness It is this method that gives the firmness and solidity to his flesh work A marked feature of Stuart's work is the total absence of all lines, his work being painted in with the brush from the beginning It is this process that gives to his modelling its strength and rotundity Stuart was pre-eminent as a colourist, and his place, judged by the highest canons in art, is unquestionably among the few recognized masters of portraiture

STUART, JOHN M'DOUALL (1818–1866), a South-Australian explorer, was born in England in 1818 and arrived in the colony about 1839 He accompanied Captain Sturt's 1844–45 expedition as draughtsman, and between 1858 and 1862 he made six expeditions into the interior, the last of which brought him on July 24 to the shores of the Indian Ocean at Port Darwin, the first to have crossed the island continent from south to north It was this transcontinental expedition which led to the territorial rights, and, in defiance of geographical position, the name of South Australia being extended over so much of central and north Australia Stuart was rewarded with £3000 and a grant of 1000 square miles of grazing country in the interior rent free for seven years His name is perpetuated by Central Mount Stuart He died in England June 5, 1866.

STUHLWEISSENBURG (Hung *Székes-Fehérvár*, Lat *Alba Regia*), the capital of the county of Fehér, and in former times also of Hungary, is situated in 47° 11′ N lat and 18° 25′ E long, in a fertile plain It is the see of one of the oldest bishoprics in the country, and has a number of religious charities, convents, and nunneries, a seminary, a gymnasium, and a real school It was the coronation and burial place of the Hungarian kings from the 10th to the 16th century, but has sunk into comparative insignificance A few years ago some very remarkable excavations were made here The town is now chiefly agricultural, its fairs, especially for horses, are famous The population (1885) numbers 27,000

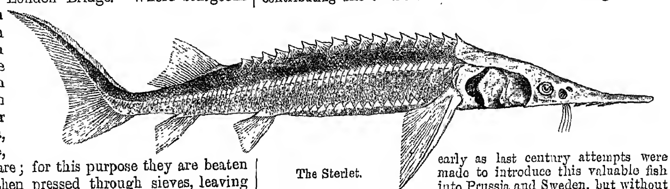
STURGEON Sturgeons (*Acipenser*) are a small group of fishes, of which some twenty different species are known, from European, Asiatic, and North American rivers The distinguishing characters of this group, as well as its position in the system, have been sufficiently indicated in the article ICHTHYOLOGY (vol xii p 687) They pass a great part of the year in the sea, but periodically ascend large rivers, some in spring to deposit their spawn, others later in the season for some purpose unknown, only a few of the species are exclusively confined to fresh water None occur in the tropics or in the southern hemisphere

Sturgeons are found in the greatest abundance in the rivers of southern Russia, more than ten thousand fish being sometimes caught at a single fishing-station in the fortnight during which the up-stream migration lasts They occur in less abundance in the fresh waters of North America, where their capture is not confined to the rivers, the majority being caught in shallow portions of the shores of the great lakes In Russia the fisheries are of immense value, yet but little is known of the sturgeon's habits, life, and early stages of development or growth Early in summer the fish migrate into the rivers or towards the shores of freshwater lakes in large shoals for breeding purposes The ova are very small, and so numerous that one female has been calculated to produce about three millions in one season The ova of some species have been observed to hatch within a very few days after exclusion Probably the growth of the young is very rapid, but we have no knowledge as to the length of time for which the fry remain in fresh water before their first migration to the sea After they have attained maturity their growth appears to be much slower, although continuing for many years Frederick the Great attempted to introduce the sterlet into Prussia, and placed a number of this fish in the Gorland Lake in Pomerania about 1780, some of these were found to be still alive in 1866, and therefore had reached an age of nearly ninety years Prof Von Baer also states, as the result of direct observations made in Russia, that the hausen (*Acipenser huso*) attains to an age of from 200 to 300 years Sturgeons ranging from 8 to 11 feet in length are by no means scarce, and some species grow to a much larger size

Sturgeons are ground feeders With their projecting wedge-shaped snout they stir up the soft bottom, and by means of their sensitive barbels detect shells, crustaceans, and small fishes, on which they feed Destitute of teeth, they are unable to seize larger prey

In countries like England, where few sturgeons are

caught, the fish is consumed fresh, the flesh being firmer than that of ordinary fishes, well-flavoured, though somewhat oily. The sturgeon is included as a royal fish in an Act of King Edward II., which assigns to the sovereign all wrecks and whales, although it probably but rarely graces the royal table of the present period, or even that of the lord mayor of London, who can claim all sturgeons caught in the Thames above London Bridge. Where sturgeons are regularly caught in large quantities, as on the rivers of southern Russia and on the great lakes of North America, their flesh is dried, smoked, or salted. The ovaries, which are of large size, are prepared for caviare; for this purpose they are beaten with switches, and then pressed through sieves, leaving the membranous and fibrous tissues in the sieve, whilst the eggs are collected in a tub. The quantity of salt added to them before they are finally packed varies with the season, scarcely any being used at the beginning of winter. Finally, one of the best sorts of isinglass is manufactured from the air-bladder. After it has been carefully removed from the body, it is washed in hot water, and cut open in its whole length, to separate the inner membrane, which has a soft consistency, and contains 70 per cent. of glutin.



The Sterlet.

The twenty species of sturgeons (*Acipenser*) are nearly equally divided between the Old and New Worlds. The more important are the following:—

(1) The Common Sturgeon of Europe (*Acipenser sturio*) occurs on all the coasts of Europe, but is absent in the Black Sea. Almost all the British specimens of sturgeon belong to this species; it crosses the Atlantic and is not rare on the coasts of North America. It reaches a large size (a length of 12 feet), but is always caught singly or in pairs, so that it cannot be regarded as a fish of commercial importance. The form of its snout varies with age (as in the other species), being much more blunt and abbreviated in old than in young examples. There are 11–13 bony shields along the back and 29–31 along the side of the body.

(2) *Acipenser güldenstädtii* is one of the most valuable species of the rivers of Russia, where it is known under the name "Ossétr"; it is said to inhabit the Siberian rivers also, and to range eastwards as far as Lake Baikal. It attains to the same large size as the common sturgeon, and is so abundant in the rivers of the Black and Caspian Seas that more than one-fourth of the caviare and isinglass manufactured in Russia is derived from this species.

(3) *Acipenser stellatus*, the "Seurruga" of the Russians, occurs likewise in great abundance in the rivers of the Black Sea and of the Sea of Azoff. It has a remarkably long and pointed snout, like the sterlet, but simple barbels without fringes. Though growing only to about half the size of the preceding species, it is of no less value, its flesh being more highly esteemed, and its caviare and isinglass fetching a higher price. In 1850 it was reported that more than a million of this sturgeon are caught annually.

(4) The sturgeon of the great lakes of North America, *Acipenser rubicundus*, with which, in the opinion of American ichthyologists, the sea-going sturgeon of the rivers of eastern North America, *Acipenser maculosus*, is identical, has of late years been made the object of a large and profitable industry at various places on Lakes Michigan and Erie; the flesh is smoked after being cut into strips and after a slight pickling in brine; the thin portions and offal are boiled down for oil; nearly all the caviare is shipped to Europe. One firm alone uses from ten to eighteen thousand sturgeons a year, averaging fifty pounds each. The sturgeons of the lakes are unable to migrate to the sea, whilst those below the Falls of Niagara are great wanderers; and it is quite possible that a specimen of this species said to have been obtained from the Firth of Tay was really captured on the coast of Scotland.

(5) *Acipenser huso*, the "Hausen" of Germany, is recognized by the absence of osseous scutes on the snout and by its flattened, tape-like barbels. It is one of the largest species, reaching the enormous length of 24 feet and a weight of 2000 pounds. It inhabits the Caspian and Black Seas and the Sea of Azoff, whence in former years large shoals of the fish entered the large rivers of Russia and the Danube. But its numbers have been much thinned, and specimens of 1200 pounds in weight have now become scarce. Its flesh, caviare, and air-bladder are of less value than those of the smaller kinds.

(6) The Sterlet (*Acipenser ruthenus*) is one of the smaller species, which likewise inhabits both the Black and Caspian Seas, and ascends rivers to a greater distance from the sea than any of the other sturgeons; thus, for instance, it is not uncommon in the Danube at Vienna, but specimens have been caught as high up as Ratisbon and Ulm. It is more abundant in the rivers of Russia, where it is held in high esteem on account of its excellent flesh, contributing also to the best kinds of caviare and isinglass. As early as last century attempts were made to introduce this valuable fish into Prussia and Sweden, but without success. The sterlet is distinguished from the other European species by its long and narrow snout and fringed barbels. It rarely exceeds a length of three feet.

Sturgeons with the snout prolonged in an extraordinary manner, so as to form a long spade-like or conical process (*Spatularia, Polyodon, Psephurus*), occur in the Mississippi and the great rivers of China and Central Asia. None of them have been made objects of trade, but special interest is attached to them from a geographical as well as palæontological point of view, the two genera last named being represented as far back as the Lias by an allied fossil genus, *Chondrosteus*, and all affording a striking proof of the close affinity of the North-American and North-Asiatic faunas of the recent period.

STURM, Jacques Charles François (1803–1855), the discoverer of the algebraic theorem which bears his name, was born in Geneva in 1803. Originally tutor to the son of Madame de Stael, he subsequently resolved, in conjunction with his school-fellow Colladon, to try his fortune in the French metropolis. Sturm soon made the acquaintance of the foremost mathematicians in the capital, and obtained employment on the *Bulletin Universel*. On the discovery of his important theorem regarding the determination of the number of real roots of a numerical equation which are included between given limits, on 23d May 1829, he rapidly rose to fortune and public honours. He was chosen a member of the French Academy in 1836, became "repetiteur" in 1838, and in 1840 professor in the Polytechnic School, and finally succeeded Poisson in the chair of mechanics in the Faculty of Science at Paris. He presented numerous memoirs to the Academy, of which his admirers have said, with some pardonable exaggeration, that an impartial posterity will place them by the side of the finest memoirs of Lagrange. Sturm died at Paris on the 18th December 1855.

STURT, Charles (d. 1869), a distinguished South-Australian explorer, was born in England, and at an early age entered the army, in which he reached the rank of captain. Having landed in Australia with his regiment (the 39th), he became interested in the geographical problems which at that time were exciting general attention. A first expedition (1828) led to the discovery of the Darling river; and a second, from which the explorer returned almost blind, made known the existence of Lake Alexandrina. For some time Captain Sturt was surveyor-general of South Australia, and he afterwards filled the post of colonial secretary. The first session of the South-Australian legislature (1851) voted him a pension of £600. From his third journey (1844–5), in which terrible hardships had to be endured, he returned quite blind, and he never altogether recovered his sight. He died at Cheltenham, England, June 16, 1869.

STUTTGART, the capital of Würtemberg, lies in the small valley of the Nesenbach, just above its confluence with the Neckar, near the centre of the kingdom and

about 115 miles west-by-north of Munich. It is charmingly situated among vine-clad and wooded hills, and stands at a height of nearly 900 feet above the sea. The town is intersected from south-west to north-east by the long and handsome Konigs-Strasse, dividing it into an upper and lower half. In all its main features it is essentially a modern town, and few of its principal buildings are older than the present century. Many of its modern edifices are, however, of considerable architectural importance, and the recent revival of the Renaissance style is perhaps nowhere better illustrated than at Stuttgart. The lower or south-eastern half contains both the small group of streets belonging to old Stuttgart and also the most important part of the new town. A large proportion of the most prominent buildings are clustered round the spacious Schloss-Platz, on or near which are the following edifices:—the new palace, an imposing structure of the 18th century, finished in 1806; the old palace, a building of the 16th century, with a picturesque arcaded court; the Konigsbau, a huge modern building, with a fine colonnade, containing ball and concert rooms, shops, &c.;

10 Museum of Art

the so called Akademie, formerly (1775–94) the seat of the Carls Schule, where Schiller received part of his education, and now occupied by the king's private library and by guard-rooms; the new courts of justice; the palaces of the crown prince and of Prince William; the Stiftskirche, or collegiate church, a fine specimen of 15th-century Gothic; the extensive royal stables; the new post-office; the theatre; and the central railway station, one of the handsomest structures of the kind in Germany. In the centre of the Schloss-Platz is the lofty jubilee column erected in memory of King William I.; in the court-yard of the old palace is a bronze equestrian statue of Count Eberhard with the Beard; and adjacent is a fine statue, designed by Thorwaldsen, of Schiller, who was a native of Wurtemberg. Among the other principal buildings are the polytechnic and architectural schools, the Late Gothic Leonhardskirche and Spitalkirche, the fine modern Gothic church of St John, the new Roman Catholic church, the neat little English church, the synagogue, and several handsome villas and mansions, chiefly in the resuscitated Renaissance style.

The art collections of Stuttgart are numerous and valuable. The museum of art comprises a picture gallery, an almost unique collection of casts of Thorwaldsen's works, and a cabinet of engravings. The royal library contains about 350,000 printed volumes, including what is said to be the largest collection of Bibles in the world, and also 4000 MSS., many of great rarity. To these may be added the industrial museum, the cabinet of coins, the museum of natural history, the fine collection of majolica in the new palace, and the museum of antiquities. The city also contains numerous excellent educational establishments, though the state university is not here but at Tubingen, and its conservatorium of music has long been renowned. Stuttgart is the centre of the publishing trade of South Germany, and has a busy industry in everything connected with the production of books. In various other industrial departments it also takes a high place, its manufactures including machinery, textile fabrics, pianos and other musical instruments, artists' colours, chemicals, sugar, and chocolate. Its trade is considerable. The population of Stuttgart in 1885 was 125,510, showing an increase of 7 per cent. since 1880. Four fifths of these are Protestants. The town proper contains about 110,000 inhabitants, while the above total is made up by adding the populations of the suburban villages of Berg, Gablenberg, and Heslach. Stuttgart is the headquarters of the 13th corps of the German army, and contains a comparatively large garrison, for which accommodation is provided in three extensive barracks within the town and on the outskirts.

To the north-east of the new palace lies the beautiful palace park, embellished with statuary and artificial sheets of water, and extending nearly all the way to Cannstatt, a distance of over two miles. Cannstatt, a town with (1880) 16,205 inhabitants, is not officially incorporated with Stuttgart, but may be looked on as practically forming part of it. Its beautiful situation on the Neckar, its tepid saline and chalybeate springs, and its educational advantages attract numerous visitors. In the environs of Stuttgart and Cannstatt lie Rosenstein, the Solitude, Hohenheim, the Wilhelma, and other royal chateaus.

Stuttgart seems to have originated in a stud ("Stuten Garten") of the early counts of Wurtemberg, and the first mention of it occurs in a document of 1229. Its importance is of comparatively modern growth, and in early Wurtemberg history we find it overshadowed by Cannstatt, the central situation of which, on the Neckar, seemed to mark it out as the natural capital of the country. After the destruction of the castle of Wurtemberg Count Eberhard, however, transferred his residence to Stuttgart (1320), and in 1482 it became the recognized capital of all the Wurtemberg territories. Even as capital its growth was slow, and it enjoys little prominence in history. At the beginning of the present century it did not contain 20,000 inhabitants, and its real advance begins with the reign of King William I. (1816–1864), who exerted himself in every way to improve and beautify his capital. In 1849 Stuttgart was the place of meeting of the so-called "Rump Parliament" (Rumpfparlament). Among its eminent natives are Hegel (b. 1770), the philosopher, and Hauff (b. 1802), the poet and story-teller.

STYRAX. See STORAX.

STYRIA (Germ. *Steiermark* or *Steyermark*), a duchy and crownland in the Cis-Leithan part of the Austrian empire, is bounded on the north by Upper and Lower

Austria, on the E. by Hungary, on the S. by Croatia and Carniola, and on the W. by Carinthia and Salzburg. Its area is 8630 square miles. Almost the entire district is mountainous, being occupied by various chains and ramifications of the eastern Alps, and, though Northern (or Upper) and Southern (or Lower) Styria are distinguished, the latter is low only in a relative sense. The North Limestone Alps touch Styria to the north of the Enns, beginning with the huge Dachstein (9830 feet), which rises on the north-west border of the duchy. To the south of the Enns the central chain of the Alps traverses Styria from south-west to north-east in two huge ranges, separated by the valleys of the Mur and the Murz, and conveniently grouped under the name of Styrian Alps. The more northerly of these two branches, forming a prolongation of the Tauern ridge, is the loftier, and culminates in the Hochgolling (9392 feet), the highest summit in Styria. The lower branch to the south is broken by the valley of the Mur, which turns abruptly to the right at its confluence with the Murz, and still farther to the north-east is crossed by the Semmering Pass. To the south of the Drave the duchy is traversed by the Karawanken Mountains (highest peak, the Stou, 7346 feet), forming a continuation of the Carnic Alps. The mountains decrease in height from west to east, and the south-east part of Styria may be described as hilly rather than mountainous. There is nowhere level ground enough to form a plain in the proper acceptation of the term, but some of the valleys contain a good deal of fertile land. The rivers of Styria all drain into the Danube; the Save and the Traun are the most important of those not already mentioned. There are numerous small mountain lakes. The climate, of course, varies with the configuration of the surface, and there is a mean annual difference of about 7° Fahr. between the temperature of the north-west and the south-east.

In spite of the irregular nature of the surface, but little of the soil can be called unproductive. About 21.40 per cent. is under tillage, 12.75 in meadow, and 16.75 in pasture, while nearly a half of the total area is covered with fine forests. The chief crops are oats, maize, rye, wheat, buckwheat, potatoes, and flax. Wine is produced in the valleys of Lower Styria, where large quantities of chestnuts are also grown. In the mountains dairy-farming is successfully carried on in the Alpine fashion, and good horses are reared in the valley of the Enns. Sheep are comparatively few, but there are large numbers of goats and swine, while poultry rearing and bee-keeping are very general in the Slavonic districts to the south. Some fairly successful attempts have also been made to breed silkworms. Trout and other fish are abundant in the rivers and mountain lakes and chamois are hunted among the higher Alps.

The great wealth of Styria, however, lies underground. Its extensive and important iron mines yield nearly one third of the iron ore raised in the Austrian empire, and its other mineral resources include brown coal, pit coal, copper, zinc, lead, graphite, a little gold and silver, nickel, alum, cobalt, salt, dyer's earth, potter's clay, marble, and good mill and building stones. The best known of its numerous mineral springs are the thermal springs of Tuffer, the alkaline springs of Rohitsch, and the brine springs of Aussee.

The chief industry of Styria is determined by its mineral richness, and iron-foundries, machine shops, and manufactures of various kinds of iron and steel goods are very numerous. A special branch is the making of scythes and sickles, which are sent out of the country in large quantities. Among its other industrial products are glass, paper, cement, oil and perfumery, shoes, cotton goods, chemicals, and gunpowder. Linen-weaving is prosecuted as a household industry. An active trade is carried on in the above named manufactures, and in brown coal, cattle, wine, and fruit. In addition to three navigable rivers (Drave, Save, Mur), the traffic of the duchy is facilitated by 600 miles of railway.

The population of Styria in 1880 was 1,213,597, equivalent to 140 per square mile, a proportion which, while not high in itself, is considerably above the rate in the other mountainous regions of the empire. Nearly the whole of these profess the Roman Catholic faith, the Protestants numbering only 8000 and the Jews about 1000. Two-thirds of the inhabitants are Germans; the remainder, chiefly found in the south parts of the duchy, in the valleys of the Drave and Save, are Slavs (Slovenes). About 65 per cent. are supported by agricultural pursuits, including forestry. The education of the crownland centres in the university of Gratz, which is attended by about 1200 students. The capital and seat of the administration is Gratz (100,000 inhabitants), which is also the headquarters of the third corps of the Austrian army; the only other town of any size is Marburg (17,600). The provincial estates consist of 63 members, including the two Roman Catholic bishops, the rector of the university, 12 representatives of the large landowners, 23 of the peasants, 19 of the towns, and 6 of the chambers of commerce. Styria sends 23 members to the imperial parliament.

In the Roman period Styria, which even thus early was famed for its iron and steel, was inhabited by the Celtic Taurisci, and divided geographically between Noricum and Pannonia. Subsequently it was successively occupied or traversed by Visigoths, Huns, Ostrogoths, Langobardi, Franks, and Avars. Towards the end of the 6th century the last-named began to give way to the Slavs (Wends), who ultimately made themselves masters of the entire district. Styria was included in the conquests of Charlemagne, and was henceforth comprised in the German marks erected against the Avar and the Slav. At first the identity of Styria is lost in the great duchy of Carinthia, corresponding more or less closely to the Upper Carinthian mark. This duchy, however, afterwards fell to pieces, and a distinct mark of Styria was recognized, taking its name from the margrave Ottocar of Steier (1056). A century or so later it was created a duchy. In 1192 the duchy of Styria came by inheritance to the house of Austria, and from that time it shared the fortunes of Upper and Lower Austria, passing like them to the Hapsburgs in 1282. The Protestant Reformation met an early and general welcome in Styria, but the dukes took the most stringent measures to stamp it out, offering their subjects recantation or expatriation as the only alternatives. At least 30,000 Protestants preferred exile, and it was not till about 100 years ago that religious liberty was recognized. The modern history of Styria has been similar to that of the other Austrian crownlands, and calls for no special remark.

STYX, a river which the Greeks fabled to flow in the world of the dead. Homer speaks of it as a river of Hades by which the gods swore their most solemn oaths, and he couples it with the Cocytus and the Pyriphlegethon, the river of wailing and the river of burning fire. Hesiod says that Styx was a daughter of Ocean, and that, when Zeus summoned the gods to Olympus to help him to fight the Titans, Styx was the first to come and her children with her; hence as a reward Zeus ordained that the most solemn oath of the gods should be by her and that her children (Emulation, Victory, Power, and Force) should always live with him. In another passage he says that Styx (whom, somewhat contradictorily, he describes as abhorred by the immortal gods) dwells far off from the gods in a beautiful house overarched with rocks and supported by tall silver pillars, which may be meant as a description of a stalactitic cave. Again Hesiod tells us that if any god, after pouring a libation of the water of Styx, forswore himself, he had to lie in a trance for a year without speaking or breathing, and that for nine years afterwards he was excluded from the society of the gods. In historical times the Styx was identified with a lofty waterfall near Nonacris in Arcadia. Pausanias describes the cliff over which the water falls as the highest he had ever seen, and indeed the fall is the highest in Greece. The scenery is wild and desolate. The water descends in two slender cascades, which, after winding among the rocks, unite and fall into the river Akrata (the ancient Crathis). The ancients regarded the water as poisonous, and thought that it possessed the power of breaking or dissolving vessels of every material, with the exception of the hoof of a horse or ass, or (according to others) of horn. The Arcadians used to swear by it on important occasions. The people in the neighbourhood still hold that the water is unwholesome, and that no vessel will hold it. They call it the Black Water or the Terrible Water.

Considering the prominence given by the ancients to an oath by the water of Styx, and comparing the effect supposed to follow from breaking that oath with the destructive power supposed to be possessed by the water, we are tempted to conjecture that drinking the water was originally a necessary part of the oath,—that in fact in the stories of the Styx we have traditions of an ancient poison ordeal such as is commonly employed amongst barbarous peoples as a means of eliciting the truth (see ORDEAL).

SUAKIN, or SUWAKIM, more correctly SAWÁKIN, the chief port of the Soudan on the Red Sea and the starting-place of caravans for Kassala and Berber, occupies a small island, placed in a deep bay in 19° 5′ N lat The custom-house and Egyptian Government offices present a good frontage to the sea, and the principal houses are stately white structures, three stories high, not unlike those of Jiddah. With these, however, are intermingled shapeless huts, each with its courtyard walled in with mats There are also the usual Greek drinking-shops, with their dirty loungers in coats and fez-caps, and a short street of coffee-houses and shops The mosques are not remarkable Passing through the bazaar and turning to the right past the tomb of Sheikh 'Ali, one comes to an open space at the head of the recent causeway which unites the island to the mainland town of Al-Kaff (Al-Keif) The main street of Al-Kaff is (or was before the recent war) the busy centre of life and movement, while the side streets are occupied by smiths, forging lance-heads and knives, leather workers, who drive a brisk trade in the amulets—passages of the Koran sewn up in leather cases—which the natives wear on their arms or round their necks, and hairdressers, greasing and powdering with the dust of a red wood the bushy locks of the Hadendoa dandies Beyond the town is a suburb of straw huts with their simple furniture of a bedstead, a few dishes, and a rubbing stone for the millet which with milk forms the chief food of the natives Here too are the booths of the silversmiths, who make bracelets, anklets, ear and nose rings, for the women The Hadendoa, a tall stalwart race, picturesquely draped in huge wrappers, to which the women add a petticoat, are most numerous on the mainland The population of the island is mixed, with a large infusion of Arab blood The export trade of Suakin before the revolt of the Soudan yielded a customs revenue of £60,000 a year, the chief articles besides the ivory, which was a Government monopoly, being gum, cotton, sesame, senna, and hides The total yearly trade was estimated at a million sterling

The environs of Suakin, though not so absolutely desert as the opposite Arabian coast, are less wooded than some points (*e g*, Sheikh Barghút) which lie as conveniently for the inland trade The island is without water and the harbour indifferent, yet the settlement is ancient Here as at Massowah traders were presumably attracted by the advantages of an island site which protected them from the nomads The country inland from all this coast belonged in the Middle Ages to the Boja (Bejah), a rude pastoral race who appear to be identical with the Blemmyes of classical writers and of whom Hadendoa, Bishárin, and Abábdah are the modern representatives The trading places seem to have been always in the hands of foreigners since Ptolemais Theron was established by Ptolemy Philadelphus for intercourse with the elephant hunters After Islam many Arabs settled on the coast and mixed with the heathen Boja, whose rule of kinship and succession in the female line helped to give the children of mixed marriages a leading position (Makrízí, *Khitat*, i 194 *sq*, translated in Burckhardt's *Travels in Nubia*, App iii) Thus in 1330 Ibn Batúta found a son of the emir of Mecca reigning in Suakin over the Boja, who were his mother's kin Makrízí says that the chief inhabitants were nominal Moslems and were called Hadárib The emir of the Hadárib was still sovereign of the mainland at the time of Burckhardt's visit (1814), though the island had an aga appointed by the Turkish pasha of Jiddah The place was settled by the Turks under Selim the Great, but Turkish (or Egyptian) control over the mainland was not effective till the Egyptian conquest of the Soudan Till the suppression of the slave trade, Suakin was an important slave port, of late years slaves have been secretly run across the Red Sea from less frequented points on the coast But legitimate commerce was rapidly growing before the revolt of the Soudan, and the port was visited by English, Egyptian, and Italian steamers

SUARDI, BARTOLOMMEO, usually known as BRAMANTINO from his master Bramante, was a distinguished painter and architect of the Milanese school He was specially famed for his knowledge of perspective, and Lomazzo (*Tratt d Pitt*, iii 1) praises him highly for the deceptive realism of his painting The dates of his birth and death are unknown, but he was probably quite young when, about 1495, he visited Rome in company with his master Bramante, there he is said to have been employed as a painter by the pope, and he evidently spent much time in studying the remains of classical buildings in Rome A number of measured drawings by his hand are still preserved in the Brera library at Milan Vasari mentions that he had seen a book of drawings by Bramantino of the early Lombardic churches of Northern Italy, such as S Ambrogio at Milan and S Pietro in Ciel d'Oro at Pavia,—a remarkable thing at a time when these noble structures were usually despised as being barbarous in style The greater part of Bramantino's frescos are now lost, partly because he was specially employed to paint the external façades of houses and public buildings, such as the mint at Milan One, however, still exists over the doorway of S Sepolcro, a highly foreshortened figure of Christ, with the Madonna and Saints He also painted some angels which still exist in the church of S Eustorgio, also in Milan In 1513 he received eighty gold crowns for a Pietà and Saints painted in the sacristy for the Cistercian monks of Chiaravalle, near Milan In 1525 he was appointed architect and painter to Francesco II of Milan, and he was employed as military engineer to reconstruct the walls of the city, which was then threatened by the army of Charles V The church of S Satiro in Milan is usually attributed to Bramantino, but it appears to have been mainly designed by Bramante Bramantino died between 1530 and 1536 He left an able pupil called Agostino di Milano, who worked chiefly as an architect

SUAREZ, FRANCISCO (1548-1617), Spanish theologian and philosopher, was born at Granada on the 5th of January 1548 After completing his studies at the university of Salamanca, he entered the Society of Jesus in 1564 The accounts of his early years represent him as backward in his development, and it was not without difficulty that he obtained admission to the order Under the direction of Father Rodriguez, however, he threw off his mental slough and discovered powers of mind of the highest order He is said to have habitually devoted seventeen hours a day to study, and wonders are reported of his prodigious memory He was soon appointed to teach philosophy at Segovia, and he afterwards taught theology at Valladolid, at Alcala, at Salamanca, and at Rome successively After taking his doctorate at Evora, he was named by Philip II principal professor of theology in the university of Coimbra Suarez may be considered almost the last eminent representative of scholasticism, and his works in twenty-three folio volumes treat, after the scholastic method and with scholastic comprehensiveness, all the main subjects of mediæval philosophy and theology In philosophical doctrine he adhered to a moderate Thomism On the question of universals he endeavoured to steer a middle course between the pantheistically inclined realism of Duns Scotus and the extreme nominalism of William of Occam The only veritable and real unity in the world of existences is the individual, to assert that the universal exists separately *ex parte rei* would be to reduce individuals to mere accidents of one indivisible form Suarez maintains that, though the humanity of Socrates does not differ from that of Plato, yet they do not constitute *realiter* one and the same humanity, there are as many "formal unities" (in this case, humanities) as there are individuals, and these individuals do not constitute a factual, but only an essential or ideal unity ("ita ut plura individua, quæ dicuntur esse ejusdem naturæ, non sint unum quid vera entitate quæ sit in rebus, sed solum fundamentaliter vel per intellectum") The formal unity, however, is not an arbitrary creation of the mind, but exists "in natura rei ante omnem operationem intellectus" In theology, Suarez attached

himself to the doctrine of Molina, the celebrated Jesuit professor of Evora. Molina tried to reconcile the doctrine of predestination with the freedom of the human will by saying that the predestination is consequent upon God's foreknowledge of the free determination of man's will, which is therefore in no way affected by the fact of such predestination. God gives to all men grace sufficient for their salvation, but some co-operate freely with this grace, while others resist it. Suarez endeavoured to reconcile this view with the more orthodox doctrines of the efficacy of grace and special election, maintaining that, though all share in an absolutely sufficient grace, there is granted to the elect a grace which is so adapted to their peculiar dispositions and circumstances that they infallibly, though at the same time quite freely, yield themselves to its influence. This mediatizing system was known by the name of "congruism." Suarez is probably more important, however, as a philosophical jurist than as a theologian or metaphysician. In his extensive work *Tractatus de Legibus ac Deo Legislatore* (reprinted, London, 1679) he is to some extent the precursor of Grotius and Pufendorf. Though his method is throughout scholastic, he covers the same ground, and Grotius speaks of him in terms of high respect. The fundamental position of the work is that all legislative as well as all paternal power is derived from God, and that the authority of every law resolves itself into His. Suarez conclusively refutes the patriarchal theory of government and the divine right of kings founded upon it,—doctrines popular at that time in England and to some extent on the Continent. Adam, he remarks, possessed only a domestic or patriarchal, not a political authority. Power by its very nature belongs to no one man but to a multitude of men; and the reason is obvious, since all men are born equal. It has been pointed out that this accords well with the Jesuit policy of depreciating the royal while exalting the papal prerogative. But Suarez is much more moderate on this point than a writer like Mariana, approximating to the modern view of the rights of ruler and ruled. In 1613, at the instigation of Pope Paul V, Suarez wrote a treatise dedicated to the Christian princes of Europe, entitled *Defensio Catholicæ Fidei contra Anglicanæ Sectæ Errores*. This was directed against the oath of allegiance which James I exacted from his subjects. James caused it to be burned by the common hangman, and forbade its perusal under the severest penalties, complaining bitterly at the same time to Philip III that he should harbour in his dominions a declared enemy of the throne and majesty of kings. In France extracts from the treatise were condemned to the flames by the parlement of Paris on similar grounds. Suarez died after a few days' illness on 25th September 1617 at Lisbon, whither he had gone to be present at an ecclesiastical conference.

The collected works of Suarez have been printed at Mainz and Lyons (1630) and at Venice (1740), also more recently at Besançon (1856-62) and in the collection of the Abbé Migne. His life has been written by Deschamps (*Vita Fr Suaresii*, Perpignan, 1671). The chief modern authorities are K. Werner's *Franz Suarez u. die Scholastik der letzten Jahrhunderte* (Ratisbon, 1861) and the third volume of Stöckl's *Geschichte der Philosophie des Mittelalters*.

SUBIACO, a town of Italy, in the province of Rome, 25 miles east of Tivoli and 42 from the capital, is picturesquely situated on the right bank of the Teverone. It has iron-works and paper-mills, and in 1881 the population of the town was 6503 (commune, 7017), having decreased from 7452 in 1868.

Subiaco, the *Sublaqueum* of the Romans, was so called from its position under the artificial lakes constructed in connexion with one of the villas of the emperor Nero. In all probability there was no town in ancient times, and the modern town of Subiaco appears to have grown up subsequent to the establishment of the Benedictine monasteries in this neighbourhood. Of these the most remarkable are Santa Scolastica,[1] which was built by the abbot Honoratus, and by the 11th century ranked as a regular principality, and Sacro Speco, which has gathered its curious cluster of buildings round the cave in which St Benedict himself found an asylum (see vol iii p 557). The points of most interest in the town, which still bears on the whole a clearly mediæval impress, are associated with Pope Pius VI. It was Pius who restored and extended the great castle, erected in 1068 by Abbot John V, and long used as a summer residence by the popes, and it was he who built the costly church of Sant' Andrea. His visit to the town in 1789 is commemorated by a triumphal arch. The first book printed in Italy was the Subiaco *Lactantius* of 1465.

SUBLEYRAS, PIERRE (1699-1749), French painter, who passed nearly his whole life at Rome, was born at Uzès (Gard) in 1699. He left France for Italy in 1728, having carried off the great prize. He there painted for the canons of Asti Christ's Visit to the House of Simon the Pharisee (Louvre, engraved by Subleyras himself), a large work, which made his reputation and procured his admission into the Academy of St Luke. Cardinal Valenti Gonzaga next obtained for him the order for Saint Basil and the Emperor Valens (small study in Louvre), which was executed in mosaic for St Peter's. Benedict XIV and all the princes of Rome sat to him, and the pope himself commanded two great paintings—the Marriage of St Catherine and the Ecstasy of St Camilla—which he placed in his private apartments. For various religious corporations at Milan, Perugia, and other places, and for various great persons many important altar-pieces were also executed; but Subleyras shows greater individuality in his curious genre pictures, which he produced in considerable number (Louvre). It is in his illustrations of La Fontaine and Boccaccio that his true relation to the modern era comes out; and his drawings from nature are often admirable for their grave sobriety of treatment (see one of a man draped in a heavy cloak in the British Museum). Exhausted by overwork, Subleyras tried a change to Naples, but returned to Rome at the end of a few months to die (28th May 1749). His wife, the celebrated miniature painter, Maria Felice Tibaldi, was sister to the wife of Trémollière.

SUCCESSION DUTY is a sum paid to the state by a person benefited by the succession to certain kinds of property. Legacies were first taxed in 1780. It was not until 1853 that a tax was levied upon succession to real property, or succession under any instrument other than a will by which property is enjoyed in succession to a deceased person. The duty is paid on succession to both real and personal property, in fact, in almost all cases which do not fall within the Legacy Duty Acts. The Succession Duty Act, 1853 (16 and 17 Vict c 51), defines succession as "every past or future disposition of property by reason whereof any person has or shall become beneficially entitled to any property, or the income thereof, upon the death of any person dying after the time appointed for the commencement of this Act, either immediately or after any interval, either certainly or contingently, and either originally or by way of substitutive limitation, and every devolution by law of any beneficial interest in property, or the income thereof, upon the death of any person dying after the time appointed for the commencement of this Act to any other person in possession or expectancy." There are certain exemptions, the most important being successions of a husband or wife, successions where the whole value is under £100, individual successions under the value of £20, and legacies and shares of personal estate chargeable under the Legacy Duty Acts. The duties levied vary from 1 to 10 per cent, according to the degree of consanguinity between the predecessor and the successor. Leasehold property and personalty directed to be converted into real estate are liable to succession and

[1] For the Santa Scolastica library, see LIBRARIES, vol. XIV. p. 530.

not to legacy duty Special provision is made for the collection of the duty in the case of joint tenants, in the case where the successor is also the predecessor, and in other dispositions of a special nature The duty is a first charge on property, but, if the property be parted with before the succession duty be paid, the liability of the successor appears to be transferred to the alienee A *bona fide* purchaser is protected by a receipt for duty, notwithstanding any suppression or mis-statement in the account on the footing of which the duty was assessed, or any insufficiency of such assessment It is usual in requisitions on title before conveyance to demand for the protection of the purchaser the production of receipts for succession duty Recent legislation has made some amendments in the law By 43 Vict c 14, s 11, succession duty may be commuted in certain cases by the Commissioners of Inland Revenue 44 Vict c 12, s 36, relieves from payment of succession duty on personal estate not exceeding £300 by payment of a sum of thirty shillings on the affidavit or inventory Section 41 exempts from payment of the 1 per cent duty in respect of property for which stamp duty has been paid on the affidavit or inventory Up to 1885 certain property vested in bodies corporate and unincorporate escaped liability to succession duty 48 and 49 Vict c 51, s 11, now imposes on such bodies (with considerable exceptions) a duty at the rate of 5 per cent on the annual value, income, or profits of the succession All the Acts which have been cited extend to the United Kingdom

In the United States succession duty is regulated by tit xxxv ch 10 of the Revised Statutes The duty varies from 1 to 6 per cent, according to the degree of consanguinity

SUCHET, Louis Gabriel, Duc d'Albufera (1770-1826), marshal of France, one of the most brilliant of Napoleon's generals, was the son of a silk manufacturer at Lyons, where he was born on 2d March 1770 He originally intended to follow his father's business, but the Revolution of 1789 altered the bent of his ambition, and, having in 1792 served as volunteer in the cavalry of the national guard at Lyons, he manifested military abilities which secured his rapid promotion As *chef de bataillon* he was present at the siege of Toulon in 1793, where he took General O'Hara prisoner During the Italian campaign of 1796 he distinguished himself in most of the important contests and was severely wounded at Cerea on 11th October In October 1797 he was appointed to the command of a demi-brigade, and in the following year his services in Switzerland were recognized by his promotion to the rank of general of brigade He then went to Egypt, but soon afterwards was recalled, and in August made chief of the staff to Brune, to whom he rendered invaluable assistance in restoring the efficiency and discipline of the army in Italy In July 1799 he was made general of division to Joubert in Italy, and, after being continued in the same office by his successors, was in 1800 named by Masséna his second in command Soon afterwards he had an opportunity of manifesting those qualities which entitle him to rank among the most daring and clever tacticians of his time, his dexterous resistance to the superior forces of the Austrians with the left of Masséna, when the right and centre were shut up in Genoa, not only prevented the invasion of France from this direction but powerfully contributed to the success of Napoleon's strategy of crossing the Alps, which culminated in the battle of Marengo on 14th June He took a prominent part in all the subsequent events of the Italian campaign till the peace of Lunéville, 9th February 1801 In the campaigns of 1805 and 1806 he greatly increased his reputation, more especially at Austerlitz, Saalfeld, Jena, Pultusk, and Ostrolenka He obtained the title of count on 19th March 1808, and, after taking part in the siege of Saragossa, was named generalissimo of the army of Aragon and governor of the province, which, by wise administration no less than by his brilliant valour, he in two years brought into complete submission He annihilated the army of Blake at Maria on 14th June 1809, and on 22d April 1810 inflicted a severe defeat on O'Donnell After being made marshal of France, 8th July 1811, he in 1812 achieved the conquest of Valencia, for which he was rewarded with the title of Duc d'Albufera By Louis XVIII he was on 4th June made a peer of France, but, having assisted Napoleon during the "hundred days," he was deprived of his peerage on 24th July 1815 He died near Marseilles on 3d January 1826 Suchet was the author of *Mémoires sur ses Campagnes en Espagne*, 2 vols, 1829-34

See C-H Barault-Roullon, *Le Maréchal Suchet*, Paris, 1854, T Choumara, *Considérations militaires sur les mémoires du Maréchal Suchet*, Paris, 1840

SU-CHOW There are in China three cities of this name which deserve mention (1) Su-chow, formerly one of the largest cities in the world, and still in 1880 credited with a population of 500,000, in the province of Kiang-su, on the great Imperial Canal, 55 miles west-north-west of Shanghai The site is practically a cluster of islands to the east of Lake Tai-hu, and streams and canals give communication with most parts of the province The walls are about 10 miles in circumference and there are four large suburbs Su-chow is a great commercial and manufacturing centre, the silk manufacture being represented by a greater variety of goods than are produced anywhere else in the empire, and the publication of cheap editions of the Chinese classics is carried to great perfection There is a Chinese proverb to the effect that to be perfectly happy a man ought to be born in Su-chow, live in Canton, and die in Lian-chow The great nine-storied pagoda of the northern temple is one of the finest in the country In 1860 Su-chow was captured by the Taipings, and, when in 1865 it was recovered by the valour and enterprise of General Gordon, the city, which had formerly been famous for its large and handsome buildings, was almost reduced to a heap of ruins Of the original splendour of the place some idea may be gathered from the beautiful native plan on a slab of marble preserved since 1247 in the temple of Confucius and reproduced in Yule's *Marco Polo*, vol i. Su-chow was founded in 484 by Ho-lu-Wang, whose grave is covered by the artificial "Hill of the Tiger" in the vicinity of the town The literary and poetic designation of Su-chow is Ku-su, from the great tower of Ku-su-tai, built by Ho-lu-Wang (2) Su-chow, formerly Tsiu-tsuan-tsiun, a free city in the province of Kan-suh, in 39° 48′ 3″ N lat (according to Sosnofskii), just within the extreme north-west angle of the Great Wall, near the gate of Jade It is the great centre of the rhubarb trade, and used to be the residence, alternately with Lian-chow-fu, of the governor of the province Completely destroyed in the Dungan insurrection (1865-72), it was recovered by the Chinese in 1873 and has been rebuilt (3) Su chow, a commercial town situated in the province of Sze-chuen at the junction of the Min river with the Yang-tse-kiang, in 28° 46′ 50″ N lat

SUCKER See Lump-sucker

SUCKLING, Sir John (1609-1642), one of the most admired poets and men of fashion at the court of Charles I, and an active spirit in politics as well as in fashionable gaieties, belonged to a Norfolk family His father was a high official under James I and a comptroller of the household under Charles I, finance seems to have been his strong point, and he managed his own affairs so well as to accumulate a considerable fortune, of which the poet was left master at the age of eighteen His earliest biographers fixed his birth in 1613, and founded on this a

reputation for extraordinary precocity in school learning Mr Alfred Suckling, who edited his works in 1836, corrected this error, ascertaining that he was born at Whitton in Middlesex and baptized on 10th February 1609 He was sent to Trinity College, Cambridge, in 1623, at what was then the usual age, and thereafter travelled on the Continent, as was also the custom for youths of his birth Returning to London, he did not long remain inactive at court, but sought experience as a soldier, volunteering into the force raised by the marquis of Hamilton for the support of Gustavus Adolphus in the Palatinate He reached Germany in July 1631 and was back at Whitehall in May 1632, but during this time he saw a good deal of hard service, being present at the battle of Leipsic and the sieges of Crossen, Guben, Glogau, and Magdeburg Reappearing at court, he at once became a prominent figure "He had the peculiar happiness of making everything that he did become him" He was ready of wit, handsome of person, wealthy and generous, a leader in all pastimes, the best bowler and the best card-player at court His happy skill in verse was only one of the distinctions of a man who excelled in everything, but, as it happened, both the king and the queen had literary tastes, and he aimed at distinction in poetry with the ardent thoroughness which seems to have been part of his character He became eminent at court just at the time when masques, after being the rage for a few years, had reached the height of their splendour and were beginning to pall, and it occurred to him to apply to the ordinary drama the improved scenery which the taste for masques had developed We can trace in his plays both the taste for spectacular effect and the admiration for the wit of Shakespeare which he shared with his royal master *Aglaura* was the first of them, and is said to have been the first play produced with elaborate stage scenery It was produced first at Christmas in 1637 with a tragic ending, then reproduced at the following Easter with ingenious changes in the fifth act which made it end happily With all its clever play on words and images, and its natural felicity of diction, it is not an interesting drama to read, the characters have no body or vitality But it is full of incident, as if the dramatist were revelling in the newly discovered power of shifting the scenes, and making the most of his advantage in having the co-operation of Inigo Jones His comedy the *Goblins* is much happier, and there the frequent changes of scene are used with great skill to maintain the liveliness of the action Suckling produced another tragedy in 1639, *Brennoralt*, it has more body than its predecessor, but shows no mastery of passion or tragic character He began still another tragedy, the *Sad One*, but was abruptly stopped in his literary career by the beginning of a tragedy in real life, the quarrel between Charles and his subjects Suckling took a prominent part for a time on the Royalist side When war was levied on the Scottish Covenanters in 1639 Suckling raised a troop of a hundred horse at his own expense and accompanied them on the bloodless expedition to the Border He was elected member for Bramber to the Long Parliament which met in November 1640, but in May of the following year he got into trouble in connexion with a plot for the escape of Strafford from the Tower and a project for calling in French aid, was charged with high treason, and fled beyond sea The circumstances of his short life in exile are obscure He continued to attract attention, and many pamphlets about him were circulated, one in particular describing how he eloped with a lady to Spain and fell into the clutches of the Inquisition The tradition is that he committed suicide in Paris some time before the end of 1642 Suckling's reputation as a poet rests not upon his plays but upon his minor pieces They have wit and fancy and at times exquisite felicity of diction The happiest as a whole is the *Ballad upon a Wedding* "Prithee, why so pale, fond lover?" is an occasional song in *Aglaura*

A collection of Suckling's poems was first published in 1646 with the title *Fragmenta Aurea* The so-called *Selections* published by Mr Alfred Suckling in 1836 is really a full edition of his poems, letters, and plays, which was re-edited, with slight additions, by Mr W C Hazlitt in 1874

SUCRE, the capital of Bolivia, formerly known as Chuquisaca, but renamed in honour of General Sucre, the first president of the republic Lying in 19° 2′ 45″ S lat and 65° 17′ W long, at a height of 9183 feet above the sea, in a valley which drains southwards to the Pilcomayo (see PLATE RIVER), it enjoys an agreeable climate and has its markets well supplied with fruits and vegetables The city is the seat of the archbishopric of La Plata and Charcas, founded in 1609, and contains a magnificent cathedral and several imposing churches and convents For a long time the university and colleges of Chuquisaca were among the most frequented in South America, and they are still of some note The inhabitants, who are mainly of Indian origin, are variously stated to number 24,000 (Ondarza) and 12,000 (*Almanac de Gotha*)

The Spanish city of Chuquisaca was founded in 1539 on the site of a Peruvian town, whose original name survived the Spanish designation of Ciudad la Plata It became in 1609 the seat of the supreme court of justice for the South American colonies—"Real Audiencia de la Plata y Charcas"—Charcas being the name of a native tribe often given to the Chuquisaca district, and even to the city (Maria de las Charcas)

SUDAN See SOUDAN

SUDBURY, an ancient borough and market town of England, chiefly in Suffolk, but partly in Essex, is situated on the river Stour, forming the boundary between the two counties, and on a branch of the Great Eastern Railway, 19 miles south of Bury St Edmunds and 58 north-east of London It is well built and well paved and contains a number of good houses It is chiefly interesting from its three parish churches of All Saints, St Peter's, and St Gregory's All Saints, dating from 1150 and consisting of chancel, nave, aisles, and tower, is chiefly Perpendicular,—the chancel, however, being Decorated It possesses a fine oaken pulpit of 1490 The church was restored in 1882 St Peter's is Perpendicular, with a unique coved nave roof St Gregory's, once collegiate, in the Perpendicular style, was partly built by Simon Tybald, archbishop of Canterbury, who was beheaded by Wat Tyler's mob He established also a college for secular priests, of which a gateway still remains The grammar-school was founded by William Wood in 1491 The principal modern buildings are the town-hall, the corn exchange, the literary and mechanics' institute, and St Leonard's hospital The town owed its early importance to the introduction of woollen manufactures by the Flemings at the instance of Edward III, but this was afterwards replaced by silk crape, jacquard satin, &c, the manufacture has now greatly declined Cocoa-nut matting is an important manufacture, and there are also flour-mills, malt-kilns, lime-works, and brick and tile yards A declining trade is carried on by the river, which is navigable up to the town The area of the municipal borough is 1459 acres, and includes, besides the parishes of All Saints, St Gregory, and St Peter, Ballingdon cum Brundon in Essex and St Bartholomew The population in 1871 was 6908, and 6584 in 1881.

Sudbury is supposed to have been in early times the chief town in Suffolk, and to have received its name in contradistinction to Norwich in Norfolk By the Conqueror it was given to Richard de Clare, and from the earls of that name it obtained important privileges It is a borough by prescription, but obtained its first charter from Mary in 1554 It obtained others from Cromwell and James II, and its governing charter is that of Charles II From the reign of Elizabeth it sent one member to parliament until it was disfranchised in 1844.

SUE, JOSEPH MARIE (1804-1859), generally known as EUGÈNE SUE, French novelist, ranked by some as the chief practitioner of the melodramatic style in fiction, was born at Paris on 10th December 1804 Unlike most voluminous writers of light literature, Sue was a man of fortune He was the son of a surgeon in Napoleon's army, and is said to have had the empress Josephine for godmother But in later life he became something very different from a Bonapartist, and his residence in Savoy for the last years of his life was due to his having been banished from France after the *coup d'état* Until his father's death in 1828 Sue pursued the same profession and was present as a surgeon both in the campaign undertaken by France in 1823 for the re-establishment of royal power in Spain and at the battle of Navarino (1828) His naval experiences supplied much of the materials of his first novels, *Kernock le Pirate*, *Attar-Gull*, *La Salamandre*, *La Coucaratcha*, and others, which were composed at the height of the romantic movement of 1830, and displayed its Byronic enthusiasm, its fancy for outlandish subjects and names, and (in a very full measure) its extravagance Then he took to more serious work, writing a naval history of France of no merit His next venture was the historical or quasi-historical novel, in which style he composed *Jean Cavalier* (1840), besides other stories of adventure About this time he was strongly affected by the socialist ideas of the day, and his attempt to display these in fiction produced (with others) his most famous and perhaps best works,—*Les Mystères de Paris* (1842) and *Le Juif Errant* (1844-45) These were among the most popular specimens of the *roman-feuilleton*, then at the height of its popularity The political and philosophical or pseudo-philosophical "purpose" continuing to gain more and more ground on the novelist's art, he followed these up with divers singular and not very edifying books, such as *Les Sept Péchés Capitaux*, *Les Mystères du Peuple*, and several others, all on a very large scale, though the number of volumes—ten, twelve, and sometimes even sixteen—gives rather an exaggerated idea of their length. Some of his books, especially the *Wandering Jew* and the *Mysteries of Paris*, were dramatized by himself, usually in collaboration with others His popularity was immense, and, despite gross faults both of art and of morality (the latter somewhat exaggerated in general estimation, at least when the work of his successors is compared), he deserved that popularity in part. By an accident, which is noteworthy in the case of other pairs of novelists (notably in those of Thackeray and Dickens, and earlier of Fielding and Richardson), his period of greatest success and popularity coincided with that of another writer, and he has been even recently, and by not despicable authorities, compared with and exalted above Alexandre Dumas This is entirely unjust, for Sue has neither Dumas's wide range of subject, nor his genial humanity of tone, nor his interest of character, nor, above all, his faculty of conducting the story by means of lively dialogue, he has, however, a command of terror which Dumas seldom or never attained, and which, melodramatic as he is, sometimes comes within measurable distance of the sublime, while his "purpose" gives him a certain energy not easily to be found elsewhere in novel-writing From the purely literary point of view his style is undistinguished, not to say bad, and his construction loose and prolix After the revolution of 1848 he sat for Paris (the Seine) in the assembly from April 1850 until his exile as above-mentioned This exile rather stimulated than checked his literary production The works of his last days, however (the chief of which is perhaps *Le Diable Médecin*), are on the whole much inferior to those of his middle period Sue died at Annecy (Savoy) on 3d August 1859.

SUETONIUS Caius Suetonius Tranquillus was one of the many second-rate authors and men of letters who lived in the early period of the Roman empire He was the contemporary of Tacitus and the younger Pliny, and his literary work seems to have been chiefly done in the reigns of Trajan and Hadrian. His father was an officer in the army and military tribune in the XIIIth legion, and he himself began life as an advocate To us he is known as the biographer of the twelve Cæsars, from Caius Julius down to Domitian These lives are valuable as covering a good deal of ground where we are without the guidance of Tacitus As Suetonius was the emperor Hadrian's private secretary, he must have had access to many important documents. It would seem from occasional references which he makes to himself in the course of the work that he was a youngish man in the reign of Domitian, and so would have had opportunities of conversing with men who had lived in the days of Tiberius, Caligula, Claudius, Nero, and had been present at the scenes of civil war and anarchy which followed the reign of the last-named The most interesting fact about Suetonius is that he was a friend and correspondent of the younger Pliny, and the fact certainly tells in his favour Several of Pliny's letters are addressed to him, and they all imply esteem and intimate friendship Sometimes we find Pliny putting in a good word for him, as, for instance, on one occasion doing his best to help him in buying a small property at a fair price, not very far from Rome, with a house of moderate size and land enough to amuse but not to engross a man of scholarly tastes (i 24) In another letter (v 10) he playfully rallies him on his dilatoriness in publishing his works Pliny does not mention the subject of these works Again he recommends him to the favourable notice of the emperor Trajan, "as a most upright, honourable, and learned man, whom persons often remember in their wills because of his merits," and he begs that he may be made legally capable of inheriting these bequests, for which under a special enactment Suetonius was, as a childless married man, disqualified Trajan granted Pliny's request (x 94, 95). Hadrian's biographer, Spartianus, tells us that Suetonius had his private secretaryship taken from him because he and some others of the imperial officials were not sufficiently observant of court etiquette towards the emperor's wife during his absence in Britain

The *Lives of the Cæsars* has always been a popular work, at least with scholars, and has been frequently edited, as well as translated into most modern languages, the latest English translation being that of Thomson in 1796 The lives of the first six Cæsars are much fuller than those of the last six, this shows that he was an industrious compiler rather than an original historian He gives us no picture of the society of the time, no hints as to the general character and tendencies of the period It is the emperor, the emperor only, who is always before us, and yet after all the portrait is but a sorry performance, drawn without any real historical judgment or insight It is the personal anecdotes he tells us, several of which are very amusing, that give his lives their chief interest, but he panders rather too much to a taste for scandal and gossip A good many of his scandalous stories about the emperors may be and probably are fictions, but at any rate they reflect the gossip of the time Still we owe him thanks for having thrown some light on an important period, parts of which are very obscure

Suetonius is said to have been a voluminous writer, and among his works Suidas mentions treatises on the *Roman Year*, *Cicero's Republic*, *The Kings*, *The Pedigree of Illustrious Romans*, and *Rome, its Institutions and Customs*, with several others,—works, it would seem, of learned research Under his name have come down to us *Lives* of Terence, Juvenal, Horace, Persius, Lucan, and his friend the younger Pliny; but the genuineness of these is highly questionable, and that of the last is hardly worth considering There is also a work entitled *De illustribus grammaticis*,—a "grammaticus" being what we should call "a professor of language and literature."

SUEUR, EUSTACHE LE (1617-1655), one of the founders of the French academy of painting, was born 19th Novem-

ber 1617 at Paris, where he passed his whole life, and where he died on 30th April 1655. His early death and retired habits have combined to give an air of romance to his simple history, which has been decorated with as many fables as that of Claude. We are told that, persecuted by Lebrun, who was jealous of his ability, he became the intimate friend and correspondent of Poussin, and it is added that, broken hearted at the death of his wife, Le Sueur retired to the monastery of the Chartreux and died in the arms of the prior. All this, however, is pure fiction. The facts of Le Sueur's life are these. He was the son of Cathelin Le Sueur, a turner and sculptor in wood, who placed his son with Vouet, in whose studio he rapidly distinguished himself. Admitted at an early age into the guild of master-painters, he left them to take part in establishing the academy of painting and sculpture, and was one of the first twelve professors of that body. Some paintings, illustrative of the Hypnerotomachia Polyphili, which were reproduced in tapestry, brought him into notice, and his reputation was further enhanced by a series of decorations (Louvre) in the mansion of Lambert de Thorigny, which he left uncompleted, for their execution was frequently interrupted by other commissions. Amongst these were several pictures for the apartments of the king and queen in the Louvre, which are now missing, although they were entered in Bailly's inventory (1710), but several works produced for minor patrons have come down to us. In the gallery of the Louvre are the Angel and Hagar, from the mansion of De Tonnay Charente, Tobias and Tobit, from the Fieubet collection, several pictures executed for the church of Saint Gervais, the Martyrdom of St Lawrence, from Saint Germain de l'Auxerrois, two very fine works from the destroyed abbey of Marmoutiers, St Paul preaching at Ephesus,—one of Le Sueur's most complete and thorough performances, painted for the goldsmiths' corporation in 1649, and his famous series of the Life of St Bruno, executed in the cloister of the Chartreux. These last have more personal character than anything else which Le Sueur produced, and much of their original beauty survives in spite of injuries and restorations and removal from the wall to canvas. The Louvre also possesses many fine drawings (reproduced by Braun), of which Le Sueur left an incredible quantity, chiefly executed in black and white chalk. His pupils, who aided him much in his work, were his wife's brother, Th. Goussé, and three brothers of his own, as well as Claude Lefebvre and Patel the landscape painter. Most of his works have been engraved, chiefly by Picart, B. Audran, Seb. Leclerc, Drevet, Chauveau, Poilly, and Desplaces. Le Sueur's work lent itself readily to the engraver's art, for he was a charming draughtsman, he had a truly delicate perception of varied shades of grave and elevated sentiment, and possessed the power to render them. His graceful facility in composition was always restrained by a very fine taste, but his works often fail to please completely, because, producing so much, he had too frequent recourse to conventional types, and partly because he rarely saw colour except with the cold and clayey quality proper to the school of Vouet; yet his St Paul at Ephesus and one or two other works show that he was not naturally deficient in this sense, and whenever we get direct reference to nature—as in the monks of the St Bruno series—we recognize his admirable power to read and render physiognomy of varied and serious type.

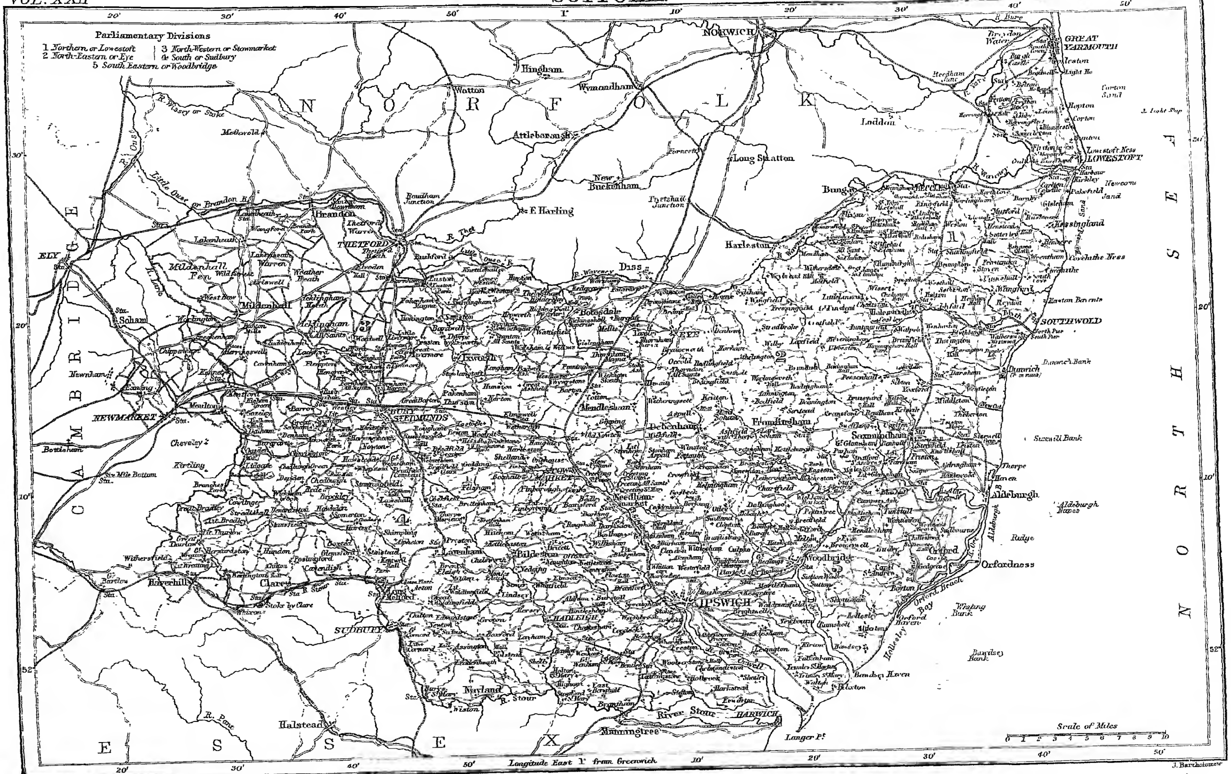
See Guillet de St Georges, *Mém. inéd.*; C. Blanc, *Histoire des Peintres*; Vitet, *Catalogue des Tableaux du Louvre*; D'Argenville, *Vies des Peintres*.

SUEZ (Suweis), the port of Egypt on the Red Sea and southern terminus of the Suez Canal (see below), situated at the head of the Gulf of Suez in 29° 58′ 37″ N. lat. and 32° 31′ 18″ E. long. (see vol. iv. pl. XXXVI.). The new harbours and quays are about 2 miles south of the town, with which they are connected by an embankment and railway, crossing a shallow which is dry at low water; the terminal lock of the freshwater canal is on the north of the town near the English hospital and the storehouses of the Peninsular and Oriental Company. The site is naturally an absolute desert, and till the water of the Nile was introduced by the freshwater canal in 1863 the water-supply of Suez was brought across the head of the gulf from the "wells of Moses" on the Arabian coast, or else carried on camels, an hour's journey, from the fortified brackish well of Bir Suweis. Thus, in spite of its favourable position for commerce, Suez before the canal was but a small place. While the canal was in progress the population rose from 5000 to 15,000, but has since declined. The canal, in fact, carries traffic past Suez rather than to it; and with its mean bazaar and mosques and mongrel population the town makes an unfavourable impression on the visitor, save for the imposing view over the gulf, with the Sinai Mountains on its eastern and Mount 'Ataka on its western shore.

A canal from the Nile to the Red Sea, the indispensable condition for the existence of a prosperous trading station at Suez, appears to have existed in very early times. Classical writers say that it was first planned by Sesostris (Rameses II.), and again undertaken by Darius I., but first completed by the Ptolemies (Arist., *Meteor.*, i. 14; Strabo, xiv. 25). The town at its terminus was Arsinoe or Cleopatris. The work was renewed by Trajan under the name *Augustus amnis*, but the trade from the East with Egypt still went mainly overland from Myus Hormus or from Berenice on the Red Sea, below the Gulf of Suez, to Coptus in Upper Egypt. Instead of Arsinoe later writers name the port of Clysma, which the Arabs corrupted into Kolzum, calling the Red Sea the Sea of Kolzum. On the Moslem conquest of Egypt the canal was restored, and is said to have remained open more than a century, till the time of Mansúr. According to Mas'údí (*Mor. ug.*, iv. 98), Hárún al-Rashíd projected a canal across the isthmus of Suez, but was persuaded that it would be dangerous to lay open the coasts of Arabia to the Greek navy. Kolzum retained some trade long after the closing of the canal, but in the 13th century it lay in ruins, and the neighbouring Suez, which had taken its place, was, as Yákút tells us, little better than a ruin. From Mokaddasí, p. 196, it may be inferred that the name of Suez originally denoted Bir Suweis. Throughout the Middle Ages, as in Roman times, the main route from Cairo to the Red Sea was up the Nile to Kús, and then through the desert to Aidháb. With the Ottoman conquest Suez became more important as a naval and trading station. Ships were built there from the 16th century onwards, and in the 18th century an annual fleet of nearly twenty vessels (Niebuhr) sailed from it to Jiddah, the port of correspondence with India. When the French occupied the town in 1798, and Bonaparte was full of his canal project, Suez was much decayed, and the conflicts which followed on its occupation in 1800 by an English fleet laid a great part of the town in ruins. The overland mail route from England to India by way of Suez was opened in 1837. The regular Peninsular and Oriental steamer service began a few years later, and in 1857 a railway was opened from Cairo through the desert. This line is now abandoned in favour of the railway which follows the canal from Suez to Ismailia, and then ascends the Wády Tumeilát to Zakázík, whence branches diverge to Cairo and Alexandria.

SUEZ CANAL. The great engineering features have been already treated of under CANAL (vol. iv. pp. 789-792). The opening of the canal to a great extent revolutionized the main lines of international traffic. More especially it has restored to the Mediterranean countries a share in the commerce of the world such as they have not possessed since the beginning of the modern period. In doing so it has naturally caused the decay of certain stations (such as St Helena) on the ocean highways previously in vogue. In the case of sailing vessels, however, the winds at the Red Sea entrance of the canal are so frequently contrary that much of the advantage of the shortness of route is lost, and these vessels consequently still take the old-fashioned détours. Traffic, too, in the canal has so greatly increased that in 1886 a vessel was considered fortunate that got through in forty-eight hours. In 1882 shipowners having expressed dissatisfaction with the condition of the service, schemes for rival canals were started,—one for a fresh-water canal from Alexandria to Cairo and thence to Suez by way of Tel-el-Kebir, another for a canal from Alexandria to Mansurah and Ismailia, and then parallel to the original canal to Suez, and a third for the construction of a second Suez canal, to be finished in 1888. These proposals all fell to the ground; but at length, in

SUFFOLK.



J. Bartholomew

ENCYCLOPÆDIA BRITANNICA, NINTH EDITION.

1886, it was determined to widen the existing canal so as to accommodate the increased traffic, and the works are now in progress Originally constructed by French capital, the Suez Canal has passed more and more into the financial ownership as well as under the political protection of England In 1875 the British Government purchased 176,602 shares from the khedive of Egypt at the price of £3,976,582, or, including commission and expenses, £4,076,622, and exchequer bonds were issued to the value of £4,000,000 By opening up a passage by which the faunal forms of the Red Sea and of the Mediterranean may respectively advance north and south into regions from which they have hitherto been excluded, the canal has produced some curious results, which have been lately investigated by Dr Conrad Keller of Zurich ("Fauna im Suez-Kanal u Diffusion de Mediter u Eryth Thierwelt," in *Neue Denkschriften d allg schweizer Ges f Naturwiss*, Zurich, 1883) Deep-sea forms are, of course, prevented passing by the shallowness of the canal, and the sandy nature of the soil, the large lakes, the currents, the disturbing influence exerted by the continual movement of vessels, and the excessive saltness of the water all tend to limit and retard the progress of even those forms most adapted to make their way through such a channel The salinity of the water is much greater than that of the Mediterranean or the Red Sea This is due mainly to two causes,—the rapid evaporation to which the water in the canal is subjected and the gradual melting of the deposits of salt (the result of previous evaporation in distant ages) in some of the depressions through which the canal is carried In the Bitter Lakes, for example, it was found in 1872 that on an average each cubic metre of water contained 156 42 lb of salt, or about three times as much as ordinary sea water A certain number of forms common to the Red Sea and the Mediterranean appear to have migrated from their original homes when in Quaternary times the isthmus was still a lagoon These being discounted, the following remain as the result of the recent connexion established between the seas (1) from the Mediterranean *Pholas candida* (as far as Ismailia), *Solen vagina*, *Sphæroma serrata* (to the south of Timsah Lake), *Cardium edule*, *Gammarus* sp (to the nearer end of the Great Bitter Lake), *Solea vulgaris*, *Umbrina cirrhosa*, *Ascidia intestinalis*, and *Labrax lupus* (to the Red Sea), (2) from the Red Sea seventeen forms were found journeying, but one only, *Mytilus variabilis*, had got out into the Mediterranean proper, *Ostracion cubicus* and *Caranx macrophthalmus* had just got *en route*, and *Pristipoma stridens* (the curious fish that utters a cry when caught), *Mactra olorina*, and *Cerithium scabridum* were found in Lake Menzaleh This lake seems to prove in the meantime an obstacle to the passage of eight other species

The following figures are in continuation of the table in vol iv p 792

Year	No of Vessels entering	Gross Tonnage	Receipts	Year	No of Vessels entering	Gross Tonnage	Receipts
1875	1494	2,940,708	£1,204,387	1881	2727	5,794,401	£2,050,974
1876	1457	3,072,107	1,229,157	1882	3198	7,122,125	2,421,835
1877	1663	3,418,949	1,339,617	1883	3307	8,051,307	2,633,912
1878	1593	3,291,535	1,272,435	1884	3284	8,319,967	2,495,124
1879	1477	3,236,942	1,214,444	1885	3624	8,985,411	2,488,297
1880	2026	4,344,519	1,629,577	1886	3100	8,183,313	2,309,218

In 1883 10 francs 50 cents were charged per ton (net tonnage), and pilotage dues amounted to 70 cents per ton on an average, on 1st July 1884 pilotage dues were abolished, and in 1885 the transit dues were reduced to 9 francs 50 cents per ton

SUFFOLK, the most easterly county in England, is bounded E by the North Sea, N by Norfolk, W by Cambridge, and S by Essex, the boundaries being chiefly the sea and rivers, it has somewhat the shape of a half moon Its greatest length north to south from Yarmouth to Landguard Point is about 50 miles, and its average length about 30, its greatest breadth from east to west is about 55 miles The total area of the county is 944,060 acres, or 1475 square miles

The principal geological formations are the Chalk and the Tertiaries, but they are frequently overlaid by drift The surface is for the most part flat or slightly undulating In the extreme north-west round Mildenhall it joins the fen country The fen land is bordered by a low range of chalk hills extending from Haverhill by Newmarket and Bury St Edmunds to Thetford The Chalk extends eastwards, but towards the south passes under the London clay and crag, which adjoins the mouths of the principal rivers and extends from Sudbury by Ipswich to Aldeburgh The easterly slopes of the Chalk are also overlaid by beds of clay, as well as by post Glacial gravels, in which flint implements and other indications of the presence of prehistoric man have been found The most interesting deposits are, however, those of the crag of the late Miocene and Pliocene periods, resting on the London clay, or, where it overlaps, on the Chalk At the base of the crag resting on the London clay is the famous Suffolk bone bed The coast-line has a length of about 52 miles, and is comparatively regular, with only slight convexities towards the sea, the bays being generally shallow and the headlands rounded and only slightly prominent The estuaries of the Deben, Orwell, and Stour are, however, of some length The shore is generally low and marshy, with occasional clay and sand cliffs The rivers flowing northwards are the Lark in the north-west corner, which passes in a north-westerly direction to the Great Ouse in Norfolk, the Little Ouse or Brandon, also a tributary of the Great Ouse, flowing by Thetford and Brandon and forming part of the northern boundary of the county; and the Waveney, which rises in Norfolk and forms the boundary between that county and Suffolk, from Palgrave till it falls into the mouth of the Yare at Yarmouth The Waveney is navigable from Bungay, and by means of Lake Lothing also communicates with Lowestoft The rivers flowing in a south-easterly direction to the North Sea are the Blyth, the Alde or Ore, which has a course for a long distance parallel to the seashore, and has its port at Orford, the Deben, from Debenham, flowing past Woodbridge, up to which it is navigable, the Orwell or Gipping, which is navigable to Stowmarket, whence it flows past Needham Market and Ipswich, and the Stour, which forms nearly the whole southern boundary of the county, receiving the Brett, which flows past Lavenham and Hadleigh, it is navigable from Sudbury and has an important port at Harwich The county has no valuable minerals Cement is dug for Roman cement, and lime and whiting are obtained in various districts

Agriculture —Suffolk is one of the most fertile counties in England In the 18th century it was famed for its dairy products The high prices of corn during the wars of the French Revolution led to the extensive breaking up of its pastures, and it is now one of the principal corn-growing counties in England There is considerable variety of soils, and consequently in modes of farming, in different parts of the county Along the sea-coast a sandy loam or thin sandy soil prevails, covered in some places with heath, on which large quantities of sheep are fed, and interspersed with tracts, more or less marshy, on which cattle are grazed The best land adjoins the rivers, and consists of a rich sandy loam, with patches of lighter and easier soil In the south-west and the centre is much fine corn land, having mostly a clay subsoil, but not so tenacious as the clay in Essex In climate Suffolk is one of the driest of the English counties, the rainfall being only half that of the counties in the west Towards the north-west the soil is generally poor, consisting partly of sand on chalk and partly of peat and open heath

According to the agricultural returns for 1886, 780,448 acres or nearly five sixths of the total area were under cultivation, 363,641 being under corn crops, 120,256 under green crops, 94,893 clover and rotation grasses, 174,970 permanent pasture, 19 flax, 57 hops, and 26,612 fallow Wheat and barley are the most important of the corn crops, having an area of 118,873 and 151,630 respectively Of green crops only 2452 were under potatoes, while 55,431 were under turnips and swedes, 36,211 under mangold, 852 under carrots, 4100 under cabbage, and 21,207 under vetches,—figures which indicate that much attention is paid to the winter feeding of cattle Horses in 1886 numbered 42,617, of which 32,262 were used solely for purposes of agriculture The breed known as Suffolk punches is one of the most valued for agricultural purposes in England (see AGRICULTURE, vol i p 385) Cattle numbered 70,695, of which 23,652 were cows and heifers in milk or in calf, and 17,322 other cattle two years old and above The breed native to the county is a polled variety, on the improvement of which great pains have been bestowed in recent years The old Suffolk cows, famous for their great milking qualities, were of various colours, yellow predominating The improved are all red Much milk is now sent to London, Yarmouth, &c Many cattle, mostly imported from Ireland, are grazed in the winter The sheep are nearly all of the black-faced improved Suffolk breed, a cross between the old Norfolk horned sheep and Southdowns Sheep numbered 433,986, of which 230,954 were one year old and above Suffolk is famous

for pigs The breed most common is small and very compact, and black in colour Pigs numbered 121,866 in 1886

The following table gives classifications of holdings in 1875 and 1885 —

Years	50 acres and under		From 50 to 100 acres		From 100 to 300 acres		From 300 to 500 acres		From 500 to 1000 acres		Above 1000 acres	
	No	Area	No	Area	No	Area	No	Area	No	Area	No	Area
1875	5667	66,251	1436	101,644	2043	336,383	387	137,894	169	110,169	12	14,744
1885	5607	64,899	1278	94,994	1872	330,133	409	154,590	174	115,089	17	22,314

Thus in 1875 there were in all 9714 holdings with 767,085 acres, and in 1885 9357 with 782,019 acres According to the latest landowners *Return* (1873) Suffolk was divided among 19,276 proprietors, holding 920,268 acres, at a valued rental of £1,784,827, or an average all over of about £1, 18s 9½d per acre Of the owners 12,511 or nearly three-fourths possessed less than one acre each The following possessed over 10,000 acres each —Lord Rendlesham, 19,869, George Tomline, 18,473, marquis of Bristol, 16,954, the maharajah Dhuleep H H Singh, 14,615, Lord Huntingfield, 11,713, earl of Stradbroke, 11,697, Sir Richard Wallace, 11,223, Lord Henniker, 10,910

Communication —The river navigation affords means of communication with different ports, and supplies facilities for a considerable amount of traffic The county is intersected in all directions by branches of the Great Eastern Railway, which touch at almost every town of importance

Manufactures and Trade —The county is essentially agricultural, and the most important manufactures relate to this branch of industry They include that of agricultural implements, especially at Ipswich, Bury St Edmunds, and Stowmarket, and that of artificial manures at Ipswich and Stowmarket, for which coprolites are dug Malting is extensively carried on throughout the county There is a gun cotton manufactory at Stowmarket, and gun flints are still made at Brandon At different towns a variety of small miscellaneous manufactures are carried on, including silk, cotton, linen, woollen, and horsehair and cocoa nut matting The principal ports are Yarmouth (situated chiefly in Norfolk), Lowestoft, Southwold, Aldeburgh, Woodbridge, and Ipswich Yarmouth is one of the most important fishing stations on the east coast of England, within the county Lowestoft is the chief fishing town Herrings and mackerel are the fish most abundant on the coasts

Administration and Population —Suffolk comprises 21 hundreds, the boroughs of Beccles (pop 5721), which has several large maltings, Bury St Edmunds (16,111), the chief town in West Suffolk, Eye (2296), an ancient market town, Ipswich (50,546), the largest town and principal port of the county, Aldeburgh (2106), the birthplace of Crabbe, Southwold (2107), a fishing town and bathing resort, the largest part (5855) of Sudbury (6584), a market and manufacturing town, and small portions of the boroughs of Thetford and Great Yarmouth, which are situated chiefly in Norfolk The other principal towns are Hadleigh (3237), with a considerable trade in corn and malt, Haverhill (3685) (partly in Essex), of great antiquity, and possessing important silk manufactures, Lowestoft (16,755), a port and fishing station, Stowmarket (4052), and Woodbridge (4544), with some coasting trade Suffolk is divided into geldable portions, in which the sovereign has the chief rights, and liberties The liberties are those of St Etheldreda, St Edmund, and the dukedom of Norfolk The court of quarter sessions is at Ipswich for the eastern division and by adjournment at Bury St Edmunds for the western There are nineteen petty and sessional divisions The hundreds of Hartismere and Stow and the borough of Eye are for petty sessional purposes included in the eastern division, and for other purposes in the western The boroughs of Bury St Edmunds, Ipswich, Great Yarmouth, and Sudbury have commissions of the peace and separate courts of quarter sessions, and Eye and Southwold have commissions of the peace For parliamentary purposes the county was until 1885 divided into East and West Suffolk, but it now constitutes five divisions, each returning one member, viz, North or Lowestoft division, North-east or Eye, North-west or Stowmarket, South or Sudbury, and South-east or Woodbridge Bury St Edmunds returns one member and Ipswich two, Eye, which formerly returned one member, was merged in the North-east division of the county in 1885 The county contains 517 civil parishes with parts of 7 others It is mostly in the diocese of Norwich From 214,404 in 1801 the population had increased by 1821 to 271,541, by 1841 to 315,073, by 1861 to 337,070, and by 1881 to 356,893, of whom 174,606 were males and 182,287 females The number of persons to an acre was 0 38 and of acres to a person 2 65

History and Antiquities —The district which now includes Norfolk, Suffolk, and a portion of Cambridge, and afterwards formed East Anglia, had in early times, on account of the marshes to the west, practically the character of a peninsula It was inhabited by the Iceni, who had their capital at Icklingham, in the north-west of Suffolk. Of the numerous barrows and tumuli belonging to this period mention may be made of those at Fornham St Geneveve and those between Aldeburgh and Snape Many of the mediæval castles were built on ancient mounds The district submitted to the Romans during the campaign of Aulus Plautius, and, although the Iceni joined the Trinobantes under Boadicea, the resistance made was ultimately fruitless A Roman road from London crossed the centre of Suffolk northwards by Stratford St Mary, Needham Market, and Billingford (Norfolk) to Norwich, another passing in a more westerly direction to Thetford Walton, where important Roman relics have been found, Dunwich (possibly *Sitomagus*), and Burgh Castle (probably *Combretonium*), one of the most perfect specimens of a Roman fort in England, enclosing an area of five acres, are supposed to have been Roman fortified stations erected for the defence of the Saxon shore Other Roman stations were at Stratford St Mary, Thetford, and Icklingham The capital of the kingdom of East Anglia was at Dunwich in Suffolk Afterwards East Anglia was divided into Norfolk and Suffolk Sigebert established an ecclesiastical diocese at Dunwich in 630, and erected a palace and a church partly out of the Roman remains The earldom of Norfolk and Suffolk was bestowed by the Conqueror on Ralph le Guader Though Suffolk suffered from incursions of the Danes, they did not effect a complete subjugation of it The prevailing terminations of the place names are Anglian The remains of old castles are comparatively unimportant, the principal being the entrenchments and part of the walls of Bungay, the ancient stronghold of the Bigods, the picturesque ruins of Mettingham, built by John de Norwich in the reign of Edward III, Wingfield, surrounded by a deep moat, with the turret walls and the drawbridge still existing, the splendid ruin of Framlingham, with high and massive walls, originally founded in the 6th century, but restored in the 12th, the outlines of the extensive fortress of Clare Castle, anciently the baronial residence of the earls of Clare, and the fine Norman keep of Orford Castle, on an eminence overlooking the sea Among the many fine residences within the county there are several interesting examples of domestic architecture of the reigns of Henry VIII and Elizabeth Throughout its whole history the annals of Suffolk have been comparatively uneventful It adhered with Norfolk to the cause of the Parliament James duke of York twice defeated the Dutch off the coast,—viz, Van Tromp off Lowestoft on 3d June 1665 and De Ruyter in Southwold Bay on 28th May 1672 Of monastic remains the most important are those of the great Benedictine abbey of Bury St Edmunds, noticed under that town, the college of Clare, originally a cell to the abbey of Bec in Normandy and afterwards to St Peter's, Westminster, converted into a college of secular canons in the reign of Henry VI, and still retaining much of its ancient architecture, and now used as a boarding-school, the decorated gateway of the Augustinian priory of Butley, and the remains of the Grey Friars monastery at Dunwich A peculiarity of the church architecture is the use of flint for purposes of ornamentation, often of a very elaborate kind, especially on the porches and parapets of the towers Another characteristic is the round towers, which are confined to East Anglia, but are considerably more numerous in Norfolk than in Suffolk, the principal being those of Little Saxham and Herringfleet, both good examples of Norman It is questionable whether there are any remains of Saxon architecture in the county The Decorated is well represented, but by far the greater proportion of the churches are Perpendicular, special features being the open roofs and woodwork and the fine fonts

SUGAR Formerly chemists called everything a "sugar" which had a sweet taste, and acetate of lead to this day is known as "sugar of lead" in commerce and familiar chemical parlance, but the term in its scientific sense soon came to be restricted to the sweet principles in vegetable and animal juices Only one of these—cane sugar—was known as a pure substance until 1619, when Fabrizio Bartoletti isolated the sugar of milk and proved its individuality In regard to all other "sugars" besides these two the knowledge of chemists was in the highest degree indefinite, and remained so until about the middle of the 18th century, when Marggraf made the important discovery that the sugars of the juices of beet, carrots, and certain other fleshy roots are identical with one another and with the sugar of the cane Lowitz subsequently showed that the granular part of honey is something different from cane sugar, this was confirmed by Proust, who found also

that Lowitz's honey sugar is identical with a crystallizable sugar present largely in the juice of the grape. Proust's investigations extended to other sweet vegetable juices also. All those investigated by him owed their sweetness to one or more of only three species,—(1) cane sugar, (2) grape sugar, (3) (amorphous) fruit sugar. Proust's results obtain substantially to this day; a number of new sugars strictly similar to these three have been discovered since, but none are at all widely diffused throughout the organic kingdom.

The quantitative elementary composition of cane sugar was determined early in the 19th century by Gay-Lussac and Thénard, who may be said to have virtually established our present formula, $C_{12}H_{22}O_{11}$. Under FERMENTATION (vol. ix. p. 93) it has been explained how Gay-Lussac (in 1811) came to mis-correct his numbers so as to bring them into accordance with what we now express by $C_6H_{12}O_6 = \frac{1}{2}C_{12}H_{24}O_{12}$. Dumas and Boullay, some years later, found that cane sugar is what Gay-Lussac and Thénard's analysis makes it out to be, while the "corrected" numbers happen to be correct for grape sugar. Dumas and Boullay's research completed the foundations of our present science of the subject. "Sugar" is now a collective term for two chemical genera named *saccharoses* (all $C_{12}H_{22}O_{11}$) and *glucoses* (all $C_6H_{12}O_6$). All sugars are colourless non-volatile solids, soluble in water and also (though less largely) in aqueous alcohol; from either solvent they can in general be obtained in the form of crystals. The aqueous solution exhibits a sweet taste, which, however, is only very feebly developed in certain species.

All sugars and their solutions have the power of turning the plane of polarization of light. In a given solution of a given kind of sugar the angle α through which the plane is turned is governed by the equation $\alpha = \pm[\alpha]lp$, where l stands for the length of solution traversed (the customary unit of length being the centimetre) and p for the number of grams of dry sugar present in a volume of solution equal to that of (say) 100 grams (3.52 oz.) of water, where, however, "gram" must be taken as merely a convenient word for "unit of weight"; $\pm[\alpha]$, *i.e.*, the special value of α for $l=1$ and $p=1$, is called the specific rotatory power of the sugar operated upon. The sign $\pm$ indicates that the plane of polarization is turned either to the right or to the left according to the nature of the species. For a given species and a given temperature $[\alpha]$ has a constant value. Supposing its value to have been determined by standard experiments and l to be known (or to be kept constant throughout and taken as unit of length), the determination of α for a given solution suffices for the calculation of p. This method is largely used industrially for the assaying of cane sugar.

Sugars, though neutral to litmus and inert towards such substances as carbonates on the one hand and aqueous acids (*qua* acids) on the other, combine with strong bases, such as caustic potash, baryta, and lime, into *saccharates*, and, when brought into contact with the strongest nitric acid (or a mixture of the same with oil of vitriol) or (at the proper temperature) with acetic anhydride, unite with these into nitrates and acetates respectively, with elimination of water. These nitrates, &c., are related to the respective sugar exactly as (to take an analogous case) nitrate of methyl, $CH_3(NO_3)$, is to methyl-alcohol, $CH_3(OH)$; only in the case of a sugar a plural of NO_3's is capable of entering into every one molecule and turning out so many HO's; hence sugars are said to be *polyvalent alcohols*. Of the several points of difference between saccharoses and glucoses the most important is that, while the latter remain unchanged when boiled with highly dilute sulphuric or hydrochloric (or certain other kinds of) acid, the former take up water and every molecule breaks up into two molecules of glucose, which in general are of different kinds. Cane sugar, for instance, yields *dextrose* and *lævulose* (so called from the direction in which they turn the plane of polarized light), thus—

$$\underset{\text{Cane Sugar}}{C_{12}H_{22}O_{11}} + H_2O = \underset{\text{Dextrose}}{C_6H_{12}O_6} + \underset{\text{Lævulose}}{C_6H_{12}O_6}$$

Cane sugar turns the plane of polarized light to the right; the mixed glucose produced is lævo-rotatory; hence the process is spoken of technically as involving the *inversion* of cane sugar, and the mixed product is called *invert sugar*. The term "inversion," however, has come somehow to be used for all decompositions which fall under the above equation; occasionally it is used even in a wider sense, to include any decomposition of a carbo-hydrate (*e.g.*, starch) into two less complex carbo-hydrates.

Fermentative changes. All sugars are liable to fermentative changes; a special character of the three principal vegetable sugars is that, when brought into contact as solutions with yeast (living cells of saccharomyces), under suitable conditions, they suffer vinous fermentation, *i.e.*, break up substantially into carbonic acid and alcohol. Dextrose and lævulose break up directly,—$C_6H_{12}O_6 = 2C_2H_6O + 2CO_2$. Cane sugar first, under the influence of a soluble ferment in the yeast, gets inverted, and the invert sugar then ferments, the dextrose disappearing at a greater rate than the lævulose.

Artificial production. It is remarkable that no sugar has ever been produced artificially even in the sense of being built up from other native organic substances of less chemical complexity. It is easy to produce dextrose from starch, or lævulose from inulin, or both from cane sugar, by inversion; but none of these processes is reversible by known methods. Yet the problem of producing cane sugar artificially may in a sense be said to have found a virtual solution at the hands of a German-American chemist, Fahlberg.[1] Fahlberg, by subjecting toluene, $C_6H_5CH_3$ (one of the components of coal-tar naphtha), to a series of operations has produced from it a body, $C_6H_4\begin{smallmatrix}CO\\SO\end{smallmatrix}NH$, which he called *saccharine*, because he found it to be about 230 times as sweet as cane sugar. This saccharine is a white crystallized solid, only slightly soluble in cold water, but sufficiently so to admit of its incorporation with jellies, puddings, beverages, &c. A mixture of one part of it with 1000 parts of ordinary grape sugar (as produced industrially from starch) is as sweet as the best cane sugar. The substance, though an antiseptic, is said to be perfectly innocuous.

Glucoses.

Glucoses. Of these a pretty large number are now known, but only lævulose and dextrose need be noticed here. Both are largely present in all kinds of sweet fruit juices and in honey. In most of these materials they are accompanied by a small proportion of cane sugar, which forcibly suggests that the glucose in fruit juices is really inverted cane sugar. But, in opposition to this surmise, the proportion of cane sugar in oranges increases during the process of ripening, and the sourest of all fruits—the lemon—contains four parts of cane for every ten of invert sugar; besides, the juices of grapes and sweet cherries contain no cane sugar whatever. According to Stammer, the young leaves of the sugar cane contain abundance of invert sugar, which gradually disappears and gives way to cane sugar as the leaves develop and ultimately dry up. In the living body of man dextrose is constantly being produced from the glycogen of the liver, to be taken up by the blood and oxidized into carbonic acid and water. In certain diseases, however (see NUTRITION, vol. xvii. p. 681), the sugar survives and passes into the urine; as much as one pound avoirdupois may be discharged by a diabetic patient in twenty-four hours. A numerous class of vegetable substances, known as *glucosides*, contain glucose of some kind in the sense that, when decomposed by boiling dilute sulphuric acid or by the action of certain ferments, they split up into glucose and some product—not a sugar—which is characteristic of the respective species. For examples, see FERMENTATION, vol. ix. p. 96.

Dextrose. *Dextrose* is being produced industrially from starch by inversion (see below), and sold as grape sugar. Such grape sugar, however, is very impure. For the preparation of pure dextrose rich diabetic urine, honey, and cane sugar are convenient materials. The method recommended by Soxhlet is to dissolve 160 grams (5.64 oz.) of powdered cane sugar in a mixture of 500 c.c. of alcohol of 85 per cent. by weight and 20 c.c. of fuming hydrochloric acid at 45° C. and to allow the solution to stand. After about a week dextrose begins to crystallize out, and, if the mixture is being frequently agitated, the deposit of crystals increases gradually. A small crop of crystals thus obtained suffices for inducing crystallization in a large supply of fresh liquor. Dextrose crystallizes from its highly concentrated aqueous solution—somewhat tardily—in minute soft crystals, united into warts or cauliflower like masses, which contain $1H_2O$ of crystal water beside $C_6H_{12}O_6$. The crystals lose their water at 100° C. From absolute alcohol it crystallizes as $C_6H_{12}O_6$. It dissolves in 1.2 parts of cold and far less of boiling water. 100 parts of alcohol of 0.837 specific gravity dissolve 1.94 parts at 17°.5 C. and 21.7 parts on boiling. In a given volume of aqueous solu-

[1] See *Amer. Chem. Jour.*, i. p. 170, ii. p. 181, and i. p. 425; short notices in *Jour. Soc. Chem. Ind.*, iv. p. 608, and February 1886.

tion 5 parts of dextrose produce the same degree of sweetness as 3 parts of cane sugar. Dextrose fuses at 146° C. and at 170° passes into glucosan, $C_6H_{10}O_5$, an almost tasteless solid, which when boiled with dilute sulphuric acid is reconverted into dextrose. If a solution of dextrose in absolute alcohol is saturated with hydrochloric acid gas at 0° C., di-glucose, $C_{12}H_{22}O_{11}$, is produced, which, however, is only isomeric with cane sugar (Gautier).

Lævulose. *Lævulose.*—The liquid part of crystalline honey consists chiefly of lævulose, but its purification is difficult. From invert sugar it can be extracted, according to Dubrunfaut, by cautious addition of slaked lime at a low temperature. The lævulose separates out as a difficultly soluble lime compound, which is separated from the mother liquor containing the dextrose by pressure and by judicious washing with cold water. The lævulosate of lime is decomposed by the exact equivalent of oxalic acid solution; then the oxalate of lime is filtered off, and the filtrate evaporated on a water-bath. The lævulose ultimately remains as a thick syrup, which formerly was supposed not to be susceptible of crystallization; but Jungfleisch and Lefranc have succeeded lately in obtaining crystals from it by means of alcohol. Lævulose is very largely soluble in water, and fully as sweet as cane sugar. It fuses at 95° C.; at 170° it passes into lævulosan, $C_6H_{10}O_5$, analogous to glucosan.

Reactions. The following reactions, though studied chiefly with dextrose, apply also to lævulose, and, substantially at least, to glucoses generally. If a solution of glucose is mixed with excess of caustic potash or soda, a solution of alkaline glucosate is formed, which, however, has little stability. If the solution is heated, the glucosate is decomposed with formation of dark-coloured (soluble) alkali salts of acid products, which, whatever they may be, are not reconvertible into glucose. Cane sugar, in these circumstances, remains substantially unchanged, and can be regenerated by elimination of the alkali. If a solution of glucose is mixed with (not too much) sulphate of copper, and an excess of caustic potash or soda be then added, no precipitate of cupric hydrate is formed, but an intensely blue solution, which, on standing in the cold gradually, and on heating promptly, deposits a red precipitate of cuprous oxide, Cu_2O, the glucose being oxidized at the expense of the dissolved CuO into soluble alkali salts of little known acids. By means of this (Trommer's) test the least trace of glucose in a solution can be discovered. Cane sugar, in the circumstances, yields cuprous oxide only on long-continued boiling. Fehling has brought this test into the following more convenient form, which, besides, admits of quantitative application. 34.65 grams (1.22 oz.) of sulphate of copper, $CuSO_4 + 5H_2O$, and 173 grams (6 oz.) of Rochelle salt (double tartrate of potash and soda) are dissolved in a solution of 70 grams (2.46 oz.) of solid caustic soda, and the intensely blue solution produced is diluted to 1000 c.c. Every c.c. of Fehling solution oxidizes about 5 milligrams (.077 grain) of dextrose (not of glucose generally). To determine an unknown weight of glucose, its solution is added to an excess of suitably diluted Fehling solution at a boiling heat, which is maintained for a sufficient time to oxidize the glucose as completely as possible,—the requisite time depending on the nature of the glucose. The cuprous oxide precipitate is allowed to settle, is then collected on a filter, and weighed directly or indirectly. From its weight the weight of the glucose is calculated,—a standard experiment with a known weight of the respective kind of pure glucose furnishing the factor. A less exact but more expeditious method is to dissolve the sugar to be analysed in water, to dilute to a known volume (not less than 200 c.c. for every gram of glucose), and to drop this solution from a burette into a measured volume of dilute Fehling solution at a boiling heat until the blue colour is just destroyed, *i.e.*, the copper just precipitated completely as Cu_2O. This method is largely used in sugar-houses in the assaying of crude cane or beetroot sugars.

Saccharoses.

Cane sugar. Of these only cane sugar, milk sugar, and maltose can be noticed here. The highest qualities of commercial cane sugar are chemically pure. Pure cane sugar crystallizes from its supersaturated syrup in colourless, transparent monoclinic prisms (exemplified in colourless candy sugar). The crystals are barely, if at all, hygroscopic; they are rather hard, and when broken up in the dark give off a peculiar kind of bluish light. Sp. gr. 1.593 at 4° C. The aqueous solution, saturated at $t°$ C., contains p per cent. of dry sugar. For

$t=$	0°	10°	20°	30°	40°	50°
$p=$	65.0	65.6	67.0	69.8	75.8	82.7

From 50° upwards the solubility increases at such a rate that a given quantum of water dissolves any quantity of sugar if the mixture is constantly kept boiling. Accordingly a sugar syrup when boiled down deposits nothing, but passes gradually into the condition of fused sugar when the boiling-point merges into the fusing point of sugar, which lies at 160-161° C. Even a cold saturated solution of sugar has the consistence of a syrup. Absolute alcohol hardly dissolves sugar at all; aqueous alcohol dissolves it the more largely the greater its proportion of water. Fused sugar freezes into a transparent glass, which is colourless if pure, but in practice generally exhibits a yellowish hue, and, if really anhydrous, remains glassy for an indefinite time. Barley-sugar and certain other confections are substantially fused sugar; but from their mode of manufacture they retain a trace of enclosed water, which constantly dissolves particles of the surrounding sugar glass to redeposit them in the less soluble form of crystals, so that barley sugar in the course of time loses its transparency through conversion into an aggregate of minute crystals. If fused sugar is kept at a few degrees above its fusing point for some time, it passes into an alloy, $C_6H_{12}O_6 + C_6H_{10}O_5$, of dextrose and lævulosan (see above). At higher temperatures it loses water and passes into anhydrides not reconvertible into cane sugar, which are known in the aggregate as "caramel,"—a most intensely brown viscous solid, easily soluble in water and in aqueous alcohol, with formation of intensely coloured solutions. Caramel (often made of dextrose) is much used as an innocent colouring agent for sauces, liqueurs, &c. A pure solution of cane sugar is said to remain unchanged on boiling (it being understood, of course, that local overheating be carefully avoided), but continued contact with even so feeble an acid as carbonic induces at least partial inversion. The statement of the unchangeability of sugar solution on boiling seems hardly credible, because a syrup boiling at all considerably above 100° C. contains plenty of molecules at temperatures above 160° C., which are bound to suffer irreversible conversion into dextrose and lævulosan (or lævulose), and even, if hot enough, caramelization. In ordinary practice, at any rate, sugar solutions on boiling do behave as indicated by this theory. Cane sugar, as already stated, unites with alkalis, alkaline earths, and other of the more strongly basic metallic oxides into saccharates. A soluble saccharate of lime, which is readily decomposible by carbonic acid and even by filtration through bone charcoal, plays a great part in the manufacture of sugar. The following strontium salt must be named, because it at least promised some years ago to occupy a similar position industrially. According to Scheibler, if strontia hydrate, $SrOH_2O + 8H_2O$, is added to a boiling 15 per cent. solution of cane sugar, then as soon as 2SrO is added for every $C_{12}H_{22}O_{11}$ the salt $C_{12}H_{22}O_{11} + 2SrO$ separates out as a sandy powder, and after addition of 2.5 times SrO almost all the sugar is precipitated. The precipitate is easily washed and decomposed by water and carbonic acid, with formation of insoluble carbonate of strontia (from which the hydrate can be reproduced) and a solution of cane sugar. The ultimate molasses produced in sugar making or refining, though they refuse to deposit crystals under any conditions, contain some 30 to 40 per cent. of real cane sugar; Scheibler's process applies to them,—to put the industrial bearings of the discovery in the proper light,—and it has led to quite a series of patents for the production of strontia; but, as far as we know, it has failed to take root in the sugar industry.

Milk Sugar occurs in the milk of mammals, and it is doubtful whether it occurs anywhere else, although Bouchardat once proved its presence in a sample marked as sugar obtained from *Sapota Achras* (the sapodilla of the West Indies). It is made industrially in Switzerland as a bye-product in the making of cheese. It passes into the whey, from which it is extracted by evaporation to a small volume, decolorization with animal charcoal, and crystallization. From the commercial product the pure substance can be obtained by repeated recrystallization from water, and ultimately by precipitation from the aqueous solution by alcohol. Milk sugar as it crystallizes from water under the ordinary conditions forms hydrated crystals of the composition $C_{12}H_{22}O_{11} + H_2O$; under certain conditions anhydrous crystals separate out. The hydrated crystals have pretty much the aspect of candy sugar, but they are less transparent, far harder, quite free from every *soupçon* of hygroscopicity, and far less sweet. They dissolve in six parts of cold and in 2.5 parts of boiling water; the solutions are not syrupy. Milk sugar is hardly soluble in alcohol. The ordinary crystals, as the formula shows, have the composition of a glucose; indeed milk sugar solution behaves to caustic alkalis and to Fehling solution as if it were a glucose. But the hydrated crystals lose their water at 130°, with formation of a residue reconvertible into the original substance by the mere action of water; besides, milk sugar is susceptible of inversion into dextrose and a specific galactose. The optical behaviour of a milk sugar solution varies according as it is derived from the ordinary crystals or the anhydride produced at 130°, and according to the time which has elapsed since its preparation; but if it stands sufficiently long the specific rotatory power assumes ultimately the same (constant) value. Milk sugar solution when brought in contact with yeast does not suffer vinous fermentation; but certain *Spaltpilze* induce a fermentation involving the formation of alcohol and of lactic acid. This process is utilized by the Kirghiz in the production of their native drink, "koumiss," made from mare's milk (see MILK, vol. xvi. p. 305). Milk sugar is used in medicine as a diluent for dry medicines. Homœopathists use it by preference. A solution of milk sugar in certain proportions of water and cow's milk is used occasionally as a substitute for mother's milk. Milk sugar.

Maltose does not occur in nature; it is largely produced along with dextrin when starch paste is acted upon by dilute sulphuric Maltose

acid or the ferment called "diastase," which is supposed to be the active agent in malt For its preparation 2 kilograms (4 40 ℔) of potato starch are made into a paste with 9 litres (15 84 pints) of water over a water bath, after allowing it to cool down to 60° or 65° C, an infusion of from 120 to 140 grams (4 23 to 5 oz) of malt made at 40° C is added The mixture is kept at from 60° to 65° for an hour, it is then boiled and filtered The filtrate is evaporated to a syrup, which is exhausted twice with alcohol of 85 per cent by weight and then once with absolute alcohol The dextrin (mostly) remains, the maltose passes into solution The alcoholic extracts are evaporated to a syrupy consistence and allowed to stand The absolute alcohol extract soon yields a crop of impure crystals of maltose, which are used to induce crystallization in the other two syrups In regard to the somewhat tedious methods of purification we refer to the handbooks of chemistry Maltose crystallizes (from alcohol on spontaneous evaporation) in fine needles of the composition $C_{12}H_{22}O_{11}+H_2O$ The H_2O goes off at 100° C Maltose is less soluble in alcohol than dextrose, to which it is otherwise very similar To caustic alkalis and Fehling solution it behaves exactly as dextrose does Like it, it suffers vinous fermentation under the influence of yeast When boiled with dilute sulphuric acid it breaks up into (so to say) dextrose and dextrose Maltose plays an important part in the brewing of alcoholic malt liquors (W D)

History

History

The original habitat of the sugar cane is not known, but it seems to have been first cultivated in the country extending from Cochin China to Bengal (De Candolle) Sugar reached the West from India, and at a comparatively late date Strabo (xv i 20) has an inaccurate notice from Nearchus of the Indian honey-bearing reed, and various classical writers of the first century of our era notice the sweet sap of the Indian reed, or even the granulated salt like product which was imported from India, or from Arabia and Opone (these being entrepôts of Indian trade),[1] under the name of saccharum or σάκχαρι (from Sanskr, *sarkara*, "gravel," "sugar"), and used in medicine The art of boiling sugar was known in Gangetic India, from which it was carried to China in the first half of the 7th century, but sugar-refining cannot have then been known, for the Chinese learned the use of ashes for this purpose only in the Mongol period, from Egyptian visitors[2] The cultivation of the cane in the West spread from Khúzistán in Persia At Gundé-Shápúr in this region "sugar was prepared with art" about the time of the Arab conquest,[3] and manufacture on a large scale was carried on at Shuster, Sús, and Askar-Mokram throughout the Middle Ages[4] It has been plausibly conjectured that the art of sugar-refining, which the farther East learned from the Arabs, was developed by the famous physicians of this region, in whose pharmacopœia sugar had an important place Under the Arabs the growth and manufacture of the cane spread far and wide, from India to Sús in Morocco (Edrísí, ed Dozy, p 62), and were also introduced into Sicily and Andalusia

In the age of discovery the Spaniards became in their turn the great disseminators of the sugar cultivation the cane was planted by them in Madeira in 1420, it was carried to San Domingo in 1494, and it spread over the occupied portions of the West Indies and South America early in the 16th century Within the first twenty years of the 16th century the sugar trade of San Domingo expanded with great rapidity, and it was from the dues levied on the imports brought thence to Spain that Charles V obtained funds for his palace-building at Madrid and Toledo In the Middle Ages Venice was the great European centre of the sugar trade, and towards the end of the 15th century a Venetian citizen received a reward of 100,000 crowns for the invention of the art of making loaf-sugar One of the earliest references to sugar in Great Britain is that of 100,000 ℔ of sugar being shipped to London in 1319 by Tomasso Loredano, merchant of Venice, to be exchanged for wool In the same year there appears in the accounts of the chamberlain of Scotland a payment at the rate of 1s 9½d per pound for sugar Throughout Europe it continued to be a costly luxury and article of medicine only, till the increasing use of tea and coffee in the 18th century brought it into the list of principal food staples The increase in the consumption is exemplified by the fact that, while in 1700 the amount used in Great Britain was 10,000 tons, in 1800 it had risen to 150,000 tons, and in 1885 the total quantity used was almost 1,100,000 tons

In 1747 Andreas Sigismund Marggraf, director of the physical classes in the Academy of Sciences, Berlin, discovered the existence of common sugar in beetroot and in numerous other fleshy roots which grow in temperate regions But no practical use was made of the discovery during his lifetime The first to establish a beet sugar factory was his pupil and successor, Franz Carl Achard, at Cunern (near Breslau) in Silesia in 1801 The processes used were at first very imperfect, but the extraordinary increase in the price of sugar on the Continent caused by the Napoleonic policy gave an impetus to the industry, and beetroot factories were established at many centres both in Germany and in France In Germany the enterprise came to an end almost entirely with the downfall of Napoleon I, but in France, where at first more scientific and economical methods of working were introduced, the manufacturers were able to keep the industry alive It was not, however, till after 1830 that it secured a firm footing, but from 1840 onwards it advanced with giant strides Now it is an industry of national importance, especially in Germany, controlling in the meantime the market against the cane-sugar trade While cane sugar was practically without a rival, the cultivation was in general highly profitable, but it was conducted under tropical skies, largely by slave labour and entirely removed from scientific supervision The staple produced at the plantations was raw sugar, which was sent to Europe to be refined It was not till the pressure of the competition with beet sugar began to make itself felt that planters realized the necessity for improving their methods of working It has now been found possible to apply many of the processes and appliances devised in connexion with the production of beet sugar to the extraction of its older rival

Manufacture

Manufacture.

CANE SUGAR MANUFACTURE —The sugar-cane (*Saccharum officinarum*) is a species of grass, the stalks or canes of which reach a height of from 8 to 15 feet, and attain a diameter of 1½ to 2 inches The stalks are divided into prominent joints or internodes, the long sheathing alternate leaves springing from each joint As the canes approach maturity they throw up a long smooth hollow joint termed the *arrow*, whence springs the flower head, consisting of beautiful feather-like loose panicles The joints are filled with a loose spongy fibrous mass, saturated with a juice which is at first watery but afterwards becomes sweet and glutinous As the joints ripen, the leaves wither and fall away and the stem becomes externally smooth, shining, and hard, containing much silica The varieties of sugar-cane in cultivation are very numerous, and are distinguished from each other by external colour, length of internodes (3½ to 10 inches), height to which they grow, richness in juice, and many other characters The four principal classes cultivated in the West Indies are the Creole or country cane, the Tahiti cane, the Batavian cane, and the Chinese cane An average sample of Tahiti cane at maturity contains—water, 71 04 per cent, sugar, 18 00, ligneous tissue and pectin, 9 56, albumen, colouring matter, and insoluble salts, 1 20, silica, 0 20 The sugar cane requires a rich, well drained, but moist soil It is propagated by slips taken from the upper part of the canes, which are planted at intervals about 5 feet apart or in close set rows 6 feet apart In the West Indies the planting takes place between June and October, and in the case of the Creole variety the canes are ready for cutting down by the beginning of January in the second following year When mature the canes are cut down close to the ground, the remaining leaves and upper shoot removed, and the stalks immediately taken to the mill for crushing The stocks left are liberally manured with crushed remains and ashes of former crops, combined with nitrogenous manures, and are covered over, they then send up a crop of new stems, termed *rattoons* The system of rattooning can be continued for several years, but the canes so treated go on declining in size and in yield of sugar The yield of canes, of course, varies within wide limits, but 20 tons per acre may be regarded as a good average crop

Cane Crushing —The juice is extracted by pressing the canes in a sugar-mill between three, or sometimes five, heavy close set rollers of iron, placed horizontally in a powerful framework or cheeks In a three-roller mill they consist of a *cane*, *top*, and *megass* roller respectively The top roller is set above and between the other two, and under its periphery is a fixed metal plate called the *trash turner*, which guides the cane coming from between the cane and top rollers into the bite between top and megass rollers Generally the cane roller is screwed up to within half an inch of the top roller, while the free space between top and megass rollers is considerably less The mill is set in motion by steam power, and the canes are fed by hand on a travelling band or carrier into the rollers If a thick feed is placed at one side and little at the other, one portion passes through imperfectly crushed, while the other severely strains the mill and may either stop the machinery or cause a breakdown by some portion giving way The yield of

[1] Lucan, iii 237, Seneca, *Epist*, 84, Pliny, *H N*, xii 8 (who supposes that sugar was produced in Arabia as well as in India), *Peripl Mar Eryth*, § 14, Dioscorides, ii 104 The view, often repeated, that the saccharum of the ancients is the hydrate of silica, sometimes found in bamboos and known in Arabian medicine as *tabashir*, is refuted by Yule, *Anglo Indian Glossary*, p 654, see also *Not et Extr des MSS de la Bibl Nat*, xxv 267 *sq*

[2] Marco Polo, ed Yule, ii 208, 212 In the Middle Ages the best sugar came from Egypt (Kazwíni, i 262), and in India coarse sugar is still called Chinese and fine sugar Cairene or Egyptian

[3] So the Armenian *Geography* ascribed to MOSES OF CHORENE (*q v* for the date of the work), St Martin, *Mém sur l'Arménie*, ii 372

[4] Istakhrí, p 91, Yákút, ii 497 Tha'álibi, a writer of the 11th century, says that Askar Mokram had no equal for the quality and quantity of its sugar, "notwithstanding the great production of 'Irák, Jorján, and India" It used to pay 50,000 pounds of sugar to the sultan in annual tribute (*Latáif*, p 107) The names of sugar in modern European languages are derived through the Arabic from the Persian *shakar*

juice obtained with an ordinary mill varies from 60 to 65 per cent. One of the most useful devices for improving the machinery is the substitution of an hydraulic attachment, which can be applied to the headstocks of any of the rollers, in place of the rigid and immovable screws and wedges of the ordinary mill. This secures a uniform pressure with the most irregular feed and much greater pressure than is possible with rigid rollers, resulting in a greatly increased yield of juice (67 to 70 per cent.) and a megass or refuse proportionately drier and therefore more available for fuel for steam-raising. The juice from the mill is led into a trough, whence it is carried by pipes to the clarifiers. But even the most perfect system of mechanical pressure leaves a large percentage of sugar in the refuse cane, and to remedy this the diffusion method (see below), which has been attended with remarkable success in the beet industry, has been also applied to the extraction of cane juice. At Aska (Madras) in India it has been found possible by that process to obtain as much as 87½ of the 90 per cent. of juice present in canes. Considerable difficulty was at first found in slicing the silicious stalks for diffusion, but this process seems to promise a much more exhaustive extraction of the juice than can be secured by mechanical means. The juice is a turbid frothy liquid of a yellowish green colour, with a specific gravity of from 1·070 to about 1·100. The variety of cane cultivated, its age, and especially the nature of the season in which it has grown as regards rain, all have an important influence on the yield of sugar. The expressed juice contains from 15 to 18 per cent. of solids, showing on a good average—sugar, 14·55 per cent., glucose, 1·65, non-saccharine solids, ·917, ash, ·283. The juice got from sugar cane is much richer in sugar and less contaminated with non-saccharine solids than that yielded by beet, and its pleasant taste and aromatic odour contrast markedly with the acrid taste and unpleasant smell of beet juice.

Purification of cane juice.

Purification of the Juice.—In the hot climates where sugar-canes grow a process of fermentation is almost immediately set up in the impure juices from the canes, causing the formation of invert sugar and later products of fermentation, and thereby a serious loss of sugar. It is therefore essential that with the least possible delay the manufacturing processes should be proceeded with. The juice is first filtered through a set of sieves to remove the mechanical impurities it carries from the mill. Then it is run into the clarifiers, a series of iron vessels capable of holding six or eight hundred gallons of juice, and in these it is heated up to about 130° Fahr., and milk of lime is added in quantity sufficient to neutralize the acid constituents it contains. The heat is then raised to just under the boiling point, when gradually a thick scum rises and forms on the surface, and when the defecation thereby effected is complete the clear liquid below is drawn off. Various other substances besides lime are employed for the defecation of juice, one of which, the bisulphite of lime in the so called Icery process, has attained considerable favour. The bisulphite is added in excess, the acids of the juice decompose a certain proportion of it, liberating sulphurous acid, which by its influence promotes the coagulation of the albuminous principles and at the same time promotes the bleaching of the liquid. In another process the green juice is first treated with sulphurous acid, which (with the natural acid constituents) is subsequently neutralized by lime. Recently also phosphoric acid has come into favour as a defecating agent.

Boiling down.

Boiling Down.—From the clarifier the juice passes on to the battery, a range of three to five pans or "coppers," heated by direct fire, in which it is concentrated down to the crystallizing point. The juice, gradually increasing in density, is passed from the one into the other till it reaches the last of the series, the *striking teach*, in which it is concentrated to the granulating point. The skimmings from these pans are collected and used for making rum. From the striking teach the concentrated juice is removed to shallow coolers, in which the crystals form. A few days later it is transferred to hogsheads in the curing house, and the molasses is drained away from the crystallized raw sugar into tanks. The sugar so obtained is the *muscovado* of the sugar-refiners, and both that and the molasses form their principal raw materials. Clayed sugar consists of raw sugar from which a portion of the adherent molasses has been dissolved by the action of moisture percolating through it from moist clay laid over its surface. Labour difficulties and scarcity of water operate against the general introduction of improved systems of working cane juice, but in many plantations central usines or sugar factories have been established with great success. In these the canes of many growers are worked up with the aid of the *triple effect apparatus*, the vacuum pan, and the centrifugal separator employed by beet manufacturers. Wetzel's pan, Fryer's concretor, and similar devices for the efficient evaporation of juice by exposing it to the action of heat in thin films over an extended surface are also in use.

Sugar beet.

BEET SUGAR MANUFACTURE.—The sugar beet is a cultivated variety of *Beta maritima* (natural order *Chenopodiaceæ*), other varieties of which, under the name of mangold or mangel wurzel, are grown as feeding roots for cattle. The plants are cultivated like turnips, and the roots attain their maturity in about five months after sowing, being gathered during September and October. The efforts of growers have been largely directed to the development of roots yielding juice rich in sugar, and especially in Germany these efforts have been stimulated by the circumstance that excise duty on inland sugar is there calculated on the roots. The duty is based on the assumption that from 12½ parts of beet 1 part of grain sugar is obtained, but in actual practice 1 part of raw sugar is now yielded by 9·27 parts of root. Moreover, when the sugar is exported a drawback is paid for that on which no duty was actually levied, and hence indirectly comes the so-called bounty on German sugar. In 1836 for 1 part of sugar 18 parts of beet were used, in 1850 13·8 parts, in 1860 12·7 parts, and now (1887) about 9·25 parts only are required. In France till recently the inland duty was calculated on the raw sugar, hence the French grower devoted himself to the production of roots of a large size yielding great weight per acre, and had no motive to aim at rich juice and economical production. Many processes, therefore, have come into use in German factories which are not available under the French methods of working. But since 1884 the French manufacturers have had the power to elect whether duty shall be levied on the roots they use or on the raw sugar they make, and a large proportion have already chosen the former. The nature of the seasons exercises much influence on the composition of sugar beet, especially on its richness in sugar, which may range from 10 to 20 per cent. The following represents the limits of average composition:—

Water		juice	84·5 to 79·0
Sugar and other soluble bodies	solids	juice	11·5 to 17·0
Cellulose and other solids	solids		4·0 4·0

The non-saccharine solids in the juice are very complex, embracing albumen, amido acids, and other nitrogenous bodies, beetroot gum, soluble pectose compounds, fat, colouring matter, with the phosphates, sulphates, oxalates, and citrates of potash, soda, lime, and iron, and silica. The relation and relative proportion of these to the sugar present are of the utmost importance.

Extraction of juice.

Two distinct ways of obtaining the juice from beet are now principally employed,—pressure and diffusion. The mechanical methods of pressure are principally used in France; the process of diffusion is all but universal in Germany. Formerly a modified diffusion process—maceration—was in use, but it has now been generally abandoned, as has also a means of separating the juice by centrifugal action. For the mechanical processes the roots have first to be reduced to a condition of fine pulp.

Method of pressure.

For this purpose the roots, thoroughly trimmed and washed, are fed into a pulping machine, in which a large drum or cylinder, armed with close set rows of saw-toothed blades, is revolved with great rapidity, so that the fleshy roots on coming against them are rasped down to a fine uniform pulp. The operation is assisted by pouring small quantities of water or of watery juice on the revolving drum, which thins the pulp somewhat, and aids the free flow of the juice in the subsequent operation. The expression of the juice is effected either by the hydraulic press or by continuous roller presses. From the hydraulic press the juice flows freely at first, but in order to obtain the largest possible yield it is necessary to moisten the first press-cake and submit it to a second pressure, whereby a thin watery juice is expressed. After having been pressed twice, the cake that is left should amount to not more than 17 per cent. of the original roots, hence, allowing 4 per cent. for ligneous tissue, &c., only about 13 per cent. of water, sugar, and soluble salts, &c., remain in the refuse. For the system of continuous pressure presses analogous to the mills employed for cane crushing are used. Many modifications of the roller press have been introduced, and, although the best express from 3 to 5 per cent. less juice than the hydraulic press, they have several advantages under the system formerly common in France, which bound the maker to return press-cake containing a certain proportion of sugar for use as a feeding-stuff on the farm. In certain forms of press the lower rollers are perforated to allow the escape of the expressed juice, in some the rollers are covered with india-rubber, so that they give an elastic squeeze on an extended surface; and in others the pulp is carried in an endless cloth through a series of rollers, being all the while subjected to gradually increasing pressure.

Diffusion process.

The diffusion process for obtaining beet juice depends on the action of dialysis in which two liquids of different degrees of concentration separated by a membrane tend to transfuse through the membrane till equilibrium of solution is attained. In the beet the cell-walls are membranes enclosing a solution of sugar. Supposing these cells to be brought into contact with pure water, then by theory, if the cells contain 12 per cent. of juice, transfusion will go on till an equal weight of water contains 6 per cent. of sugar, while by the passage of water into the cell the juice there is reduced to the same density. Taking the 6 per cent. watery solution and with it treating fresh roots containing again 12 per cent., a 9 per cent. solution will be attained, which on being brought a third time in contact with fresh roots would be raised to a density of 10·5. Thus theoretically seven eighths of the whole sugar would be obtained at the third operation, and it is on this theory that the diffusion process is based. In working the process a range of

ten or twelve diffusers are employed, eight being in operation while the others are being emptied, cleaned, and refilled These diffusers consist of large close upright cylinders capable of holding each two or three tons of sliced roots They are provided with manholes above, perforated false bottoms, and pipes communicating with each other, so that the fluid contents of any one can be forced by pressure into any other In working, pure water from an elevated tank is run into No 1 cylinder, which contains the slices almost exhausted of their soluble contents, it percolates the mass, and by pressure passes into No 2, where it acts on slices somewhat richer in juice So it goes through the series, acquiring density in its progress and meeting in each successive cylinder slices increasingly rich in juice Before entering the last cylinder the watery juice is heated, and under the combined influence of heat and pressure the juice within the cylinder becomes richly charged with sugar No 1 cylinder when exhausted is disconnected, No 2 then becomes No 1, and a newly charged cylinder is joined on at the other extremity, and so the operation goes on continuously The juice ultimately obtained is diluted with about 50 per cent of water, but it is of a comparatively pure saccharine quality, with less gummy, nitrogenous, and fibrous impurities than accompany the juice yielded by mechanical means

Purification of beet juice If the juice obtained by any process were a pure solution of sugar the manufacturing operations would be few and simple But beet juice is at best a very mixed solution, containing much gum acid bodies, nitrogenous matter, and various salts These adhere to the saccharine solution with the utmost obstinacy, they attack the sugar itself and change crystalline into invert sugar, communicating to it a dirty brown colour and a disagreeable acrid taste and smell To separate as far as possible the non saccharine constituents and to remove the colour from the juice are troublesome tasks The preliminary purification embraces two sets of operations,—first the treatment of the juice with lime and carbonic acid, secondly, filtration through animal charcoal Under the old method of working the juice is first boiled in a copper pan with milk of lime to the extent of from ½ to 1 per cent of lime to the weight of juice operated on The boiling serves to coagulate the albuminoids, while the lime forms with certain of the other impurities an insoluble precipitate and in part combines with the sugar to form a soluble saccharate of lime The insoluble lime combination and the coagulum rise as a scum over the surface of the juice, and the latter, now comparatively clear, is drawn off by a siphon pipe, to be treated in another vessel with carbonic acid The acid breaks up the saccharate of lime and forms insoluble carbonate of lime, which in precipitating carries down further impurities with it After settlement the clear juice is drawn off and the precipitated slime pressed in a filter press, whereby it gives up the juice it contains As now commonly conducted these operations—treating with lime and carbonic acid—are combined, according to the method devised by Jelinek The juice to be purified is heated and treated with as much as 5 per cent of lime, while carbonic acid is simultaneously injected into the mass The juice meantime is raised to a temperature just under boiling point The addition of such a large amount of lime effects the precipitation of a great proportion of the non-saccharine constituents of the juice The whole mass of turbid liquid formed by this treatment is forced into a filter press, and there the lime compounds and impurities are separated with great rapidity from the saccharine juice Numerous other methods of purification have been proposed, and to some extent have met with favourable reception, but of these we can only mention that of Dubrunfaut and De Massy, in which baryta is substituted for lime, thereby producing an insoluble barium saccharate, and the analogous process of Scheibler, in which strontia is employed in the same sense, producing likewise insoluble strontia saccharate The juice, which still contains much saline and other non-saccharine matter, is next filtered through animal charcoal, this largely removes colouring matter and carries away a further proportion of the salts Charcoal filtering is an expensive process, being, moreover, a feature of the subsequent refining, many attempts have been made to dispense with it, and the success of the Jelinek method in producing a comparatively pure and colourless juice has given rise to hopes that it may at this stage be yet dispensed with

Crystallization The next operation consists in concentrating the comparatively pure but thin and watery juice,—a work formerly done in open pans by direct firing, but now carried out in closed vessels, in which the vacuum pan principle of boiling is brought into play The apparatus consists of a series of three closed vessels, hence called a "triple effect," although in some cases a two vessel apparatus or double effect is employed These pans are provided internally with a series of closed pipes for steam-heating, the steam from the boiler of the first passing by a pipe into the worm of the second, and similarly the steam from the second into the worm of the third when a third pan is employed The steam which rises in the third pan is drawn off by a condenser and vacuum pump, and, as the vacuum so created acts through the whole series, the juice is evaporated and concentrated at a comparatively low temperature by the agency of the steam supplied to the first pan The juice increases in gravity as it is drawn from the one pan to the other, till by the time it is run off from the third cylinder it has attained a concentration representing a gravity of about 25 Baumé This concentrated juice is while in a heated condition filtered through fresh charcoal, from which it comes ready for boiling down to crystallization To bring the dense juice to the crystallizing point it is necessary to conduct the evaporation at the lowest possible temperature High temperature increases the uncrystallizable at the expense of the crystallizable portion, and burns some proportion into caramel, which darkens the liquid and the resulting sugar crystals Boiling down at low temperature is effected by the use of the vacuum pan, a closed globular vessel in which by the aid of a condenser and air pump a vacuum is maintained over the boiling juice and the boiling point is lowered in proportion to the decrease of air pressure In vacuum pan boiling the thick juice may simply be concentrated to that degree of density from which, on cooling, the crystals will form, or the crystals may be allowed to separate from the mother liquor in the pan while the boiling proceeds, these crystals, forming nuclei, increase in size from the concentration of fresh charges of juice added from time to time By this method the boiled down juice as it leaves the pan consists of a grainy mass of crystals floating in a fluid syrup

Separation of crystals from molasses After being allowed to cool, the mass is fed into the drum or basket of a centrifugal machine, which by its rapid rotation separates the fluid molasses from the crystals, driving the liquid portion through the meshed wall of the basket For further cleaning of the crystals from adherent syrup a small quantity of either water or pure syrup is added to the drum, and is likewise forced through the sugar crystals by centrifugal action Steam also is employed for cleaning the crystals whilst in the centrifugal machine The syrup from the first supply of sugar is returned to the vacuum pan, again boiled, and treated as above for a second supply of less pure sugar, similarly a third supply is yielded by the drainings of the second The molasses from the third supply is a highly impure mixture of crystallizable and invert sugar, potash, and other salts, smelling and tasting powerfully of its beet origin Many methods have been tried to recover the large amount of sugar contained in this molasses That most extensively employed is the osmose process originated by Dubrunfaut, in which, by the application of a dialyser, it is found that the salts pass through the membrane more rapidly than does sugar The elution process of Scheibler, which depends on the formation of a saccharate of lime, and the more recent strontia process of the same chemist, in which a strontiate of lime is formed, are also much employed Another means of utilizing the molasses consists in fermenting and distilling from it an impure spirit for industrial purposes

Refining *Sugar Refining* — Sugar-refiners deal indifferently with raw cane and beetroot sugars which come into the market, and by precisely the same series of operations The sugar is first melted in charges of 5 or 6 tons in *blow-ups*,—cast iron tanks fitted with mechanical stirrers and steam-pipes for heating the water The solution called *liquor* is brought to a certain degree of gravity, from 25 to 33 Baumé, and formerly it was the practice to treat it, especially when low qualities of sugar were operated on, with blood albumen The hot liquor is next passed through twilled cotton bags encased in a meshing of hemp, through which the solution is mechanically strained From 50 to 200 of these filters are suspended in close chambers, in which they are kept hot, from the bottom of a perforated iron tank, each perforation having under it a bag These bags have from time to time to be taken off for cleaning out and washing From the bag filter the liquor is passed for decolorizing through beds of animal charcoal enclosed in cisterns to a depth of from 30 to 50 feet, the sugar being received into tanks for concentration in the vacuum pan In that apparatus it is "boiled to grain," and the treatment is varied according to the nature of the finished sugar to be made To make loaves small crystals only are formed in the pan, and the granular magma is run into steam-jacketed open pans and raised to a temperature of about 180° to 190° Fahr, which liquefies the grains The hot solution is then cast into conical moulds, the form of the loaf, in which the sugar as it cools crystallizes into a solid mass, still surrounded and mixed with a syrup containing coloured and other impurities After thorough settling and crystallization, a plug at the bottom of the mould is opened and the syrup allowed to drain away To whiten the loaves they are treated with successive doses of saturated syrup, ending with a syrup of pure colourless sugar These doses are poured on the upper side of the cone, and, percolating down through the porous mass, carry with them the impure green syrup which still may adhere to the crystals The liquor which obstinately remains in the interstices is driven out by suction or centrifugal action; the loaf is rounded off, papered, and placed in a stove for drying The syrup which drains from the loaves is sold as golden syrup. When refined crystals are to be made the contents of the vacuum pan are passed into the centrifugal machine, the syrup is then driven off by rotation, and the crystals purified either by adding pure syrup to the revolving basket or by blowing steam through it

There are numerous modified and subsidiary processes connected with refining, as well as with all branches of the sugar industry, regarding which it is not possible here to enter into detail The industry is essentially progressive and subject to many changes

Sorghum sugar. SORGHUM SUGAR.—The stem of the Guinea corn or sorghum (*Sorghum saccharatum*) has long been known in China as a source of sugar, and the possibility of cultivating it as a rival to the sugar cane and beetroot has attracted much attention in America The sorghum is hardier than the sugar cane, it comes to maturity in a season, and it retains its maximum sugar content a considerable time, giving opportunity for leisurely harvesting The sugar is obtained by the same method as cane sugar The cultivation of sorghum sugar has not found much favour in the United States, the total yield from that source in 1885 did not exceed 600,000 lb

Maple sugar. MAPLE SUGAR.—The sap of the rock or sugar maple, *Acer saccharinum*, a large tree growing in the United States and Canada, yields a local supply of sugar, which also occasionally finds its way into commerce The sap is collected in spring, just before the foliage develops, and is procured by making a notch or boring a hole in the stem of the tree about 3 feet from the ground A tree may yield 3 gallons of juice a day and continue flowing for six weeks, but on an average only about 4 lb of sugar are obtained from each tree, 4 to 6 gallons of sap giving 1 lb of sugar The sap is purified and concentrated in a simple manner, the whole work being carried on by farmers, who themselves use much of the product for domestic and culinary purposes The total production of the United States ranges from 30,000,000 to 50,000,000 lb, principally obtained in Vermont, New York, Ohio, and Pennsylvania In Canada also a considerable quantity of maple sugar is collected for domestic use

Palm sugar. PALM SUGAR.—That which comes into the European market as *jaggery* or *khaur* is obtained from the sap of several palms the wild date (*Phœnix sylvestris*), the Palmyra (*Borassus flabelliformis*), the cocoa nut (*Cocos nucifera*), the gomuti (*Arenga saccharifera*), and others The principal source is *Phœnix sylvestris*, which is cultivated in a portion of the Ganges valley to the north of Calcutta The trees are ready to yield sap when five years old, at eight years they are mature, and continue to give an annual supply till they reach thirty years The collection of the sap (toddy) begins about the end of October and continues, during the cool season, till the middle of February The sap is drawn off from the upper growing portion of the stem, and altogether an average tree will run in a season 350 lb of toddy, from which about 35 lb of raw sugar—jaggery—is made by simple and rude processes Jaggery production is entirely in native hands, and the greater part of the amount made is consumed locally, it only occasionally reaches the European market

Starch sugar. STARCH SUGAR.—This, known in commerce as glucose or grape sugar, an abundant constituent of sweet fruits, &c (see p 623 above), is artificially elaborated on an extensive scale from starch The industry is most largely developed in Germany, where potato starch is the raw material, and in the United States, Indian corn starch being there employed The starch is acted on by a weak solution of sulphuric acid, whereby soluble starch is formed, which ultimately results in a mixture of glucose and dextrose in varying proportions, constituting the starch sugar of commerce The operations embrace the boiling of the starch with water containing the requisite proportion of acid, the neutralization of the acid with lime, and the formation of a precipitate of sulphate of lime, which is separated by filtration in a filter press The filtered liquid is, when necessary, deprived of colour by passing it through a bed of animal charcoal, and then it is concentrated to a density of from 40 to 45 Baumé in a vacuum pan If the resulting syrup contains little dextrin it will on cooling slowly solidify into a granular concretionary mass, but if much dextrin is present it remains in the condition of a syrup Starch sugar is very largely used by brewers and distillers, and by liqueur makers, confectioners, and others for making fruit and other syrups Burnt to caramel, it is also employed to colour beverages and food substances As an adulterant it is largely employed in the honey trade and for mixing with the more valuable cane sugar In 1885 there were about fifty factories in Germany engaged in starch sugar making, in which 10,000 tons of hard sugar, 20,000 tons of syrup, and 1250 tons of "colour" were made.

Commerce

Commerce. At the present time, judging by the amount sent to the market, cane and beet sugars are produced in about equal amount, but, since vast quantities of cane sugar are grown and consumed in India, China, and other Eastern countries of which we get no account, there cannot be a doubt that the annual production of cane far exceeds that of beet sugar Still, as a growth of not more than forty years, the dimensions to which the beet sugar trade has attained are certainly remarkable But these dimensions would not have been so suddenly attained had it not been for the system of protection established in the producing countries and of bounties paid to the beet manufacturers on exporting their produce The United Kingdom is the only open market for sugar, which is consequently sold there at an unprecedentedly low price The following table shows the relative proportions of the beet and the cane sugar trade and the principal sources of the supply for 1880 85 —

	1880 81	1881 82	1882 83	1883 84	1884 85
1 BEET SUGAR	Tons	Tons	Tons	Tons	Tons
German empire	594,223	644,775	848,124	986,000	1,155,000

SUGAR-BIRD, the English name commonly given in the West India Islands to the various members of the genus *Certhiola* (generally regarded as belonging to the Family *Cœrebidæ*[1]) from their habit of frequenting the curing-houses where sugar is kept, apparently attracted thither by the swarms of flies These little birds on account of their pretty plumage and their familiarity are usually favourites They often come into dwelling-houses, where they preserve great coolness, hopping gravely from one piece of furniture to another and carefully exploring the surrounding objects with intent to find a spider or insect In their figure and motions they remind a northern naturalist of a Nuthatch, while their coloration—black, yellow, olive, grey, and white—recalls to him a Titmouse They generally keep in pairs and build a domed but untidy nest, laying therein three eggs, white blotched with rusty-red Apart from all this the genus presents some points of great interest Mr Sclater (*Cat B Br Museum*, xi pp 36-47) recognizes 18 "species," therein following Mr Ridgway (*Proc U S Nat Museum*, 1885, pp 25-30), of which 3 are continental with a joint range extending from southern Mexico to Peru, Bolivia, and south-eastern Brazil, while the remaining 15 are peculiar to certain of

[1] Known in French as *Guit-guits*, a name used for them also by some English writers The *Guitguit* of Hernandez (*Rer Medic N Hisp Thesaurus*, p 56), a name said by him to be of native origin, can hardly be determined, though thought by Montbeillard (*Hist Nat Oiseaux*, v. p 529) to be what is now known as *Cœreba cærulea*, but that of later writers is *C cyanea.* The name is probably onomatopoetic, and very likely analogous to the "Quit" applied in Jamaica to several small birds

the Antilles, and several of them to one island only Thus *C caboti* is limited, so far as is known, to Cozumel (off Yucatan),[1] *C tricolor* to Old Providence, *C flaveola* (the type of the genus) to Jamaica, and so on, while islands that are in sight of one another are often inhabited by different "species" Further research is required, but even now the genus furnishes an excellent example of the effects of isolation in breaking up an original form, while there is comparatively little differentiation among the individuals which inhabit a large and continuous area The non-appearance of this genus in Cuba is very remarkable (A N)

SUGDEN, EDWARD BURTENSHAW See ST LEONARDS, LORD

SUHL, a manufacturing town in an isolated portion of Prussian Saxony, is picturesquely situated on the Lauter, on the southern slope of the Thuringian Forest, 6½ miles to the north-east of Meiningen and 29 miles to the south-west of Erfurt The armourers of Suhl are mentioned as early as the 9th century, but they enjoyed their highest vogue from 1550 to 1634 The knights of south Germany especially prized the swords and armour of this town, and many of the weapons used in the mediæval campaigns against the Turks and in the Seven Years' War are said to have been manufactured at Suhl Its old popular name of the "armoury of Germany" is more appropriate, however, to its past than to its present position, for, already seriously crippled by the ravages of the Thirty Years' War and by frequent conflagrations, it has suffered considerably in more modern times from the competition of other towns, especially since the introduction of the needle-gun It still contains, however, large factories for firearms (military and sporting) and side arms, besides iron-works, machine-works, potteries, and tanneries The once considerable manufacture of fustian has declined A brine spring (Soolquelle) at the foot of the neighbouring Domberg is said to have given name to the town The population in 1880 was 9937 and 10,605 in 1885 Suhl, made a town in 1527, belonged to the early principality of Henneberg, and formed part of the possessions of the kingdom of Saxony assigned to Prussia by the congress of Vienna

SUICIDE The phenomenon of suicide has at all times attracted a large amount of attention from moralists and social investigators Though of very small dimensions, even in the countries where it is most prevalent, its existence is rightly looked upon as a sign of the presence of maladies in the body politic which, whether remediable or not, deserve careful examination To those who look at human affairs from a theological standpoint, suicide necessarily assumes a graver aspect, being regarded, not as a minute and rather obscure disease of the social organism, but as an appalling sign of the tendency of man to resist the will of God Compare FELO DE SE As a great number of persons are, either directly or indirectly, under the influence of the theological bias, and as the act of suicide is in itself of a striking character to the imagination, the importance of the phenomenon from a sociological point of view has been to some extent exaggerated, especially in those countries of the Continent where suicides are most numerous Moreover, the matter has during the last twenty years become of direct interest to the Governments of those countries where the whole able-bodied male population are more or less under the control of a military organization, for, rightly or wrongly, a portion of the recent considerable increase in the suicide rate of Prussia, Saxony, Austria, and France is attributed to dislike of military service It may be observed in passing that the suicide rate among soldiers is high in all countries, Great Britain not excepted, as was shown by Mr W. H Millar in the *Journal of the Statistical Society*, vol xxxvii, 1874, and more recently by Dr Ogle in the same *Journal*, vol xlix (March), 1886 As enlistment is voluntary in the United Kingdom, the alleged dislike to conscription cannot be the sole cause of the high rate prevailing in some of the Continental states Before referring to the more general characteristics of suicide, it will be well to furnish some idea of its magnitude in relation to the category of social phenomena to which it belongs, namely, death The following tables are constructed for this purpose The first (I) gives the absolute number of cases of suicide as officially stated in a number of countries for a series of

I *Statement of the Number of Cases of Suicide in the Principal Countries of Europe during the undermentioned Periods and Years*

[1] Uncertain data [2] Still births are excluded
[3] Adding natural increase of 1868 to population of 1867 (Kolb)
[4] Estimate, deducting natural increase of 1869-1870 from figure in census of 1871 [5] 159,186 including still births

[1] In the article BIRDS (in p 749) attention was drawn to what was then believed to be a fact—namely, that the form found in this island was identical with that which inhabits the Bahamas, but now the two forms are regarded as distinct

years. Table II (A, B, C) refers to three separate years and shows the number of cases of suicide relatively to all the deaths and to the population for certain countries. The totals for the countries in question are also given. Table I is obtained from Morselli (Table I.) with the addition of figures that have been published since his work appeared.[1] Table III. gives the figures relating to three States of the American Union which have published statistics on the subject.

II. B.—1876.

Countries	Estimated Population in the Middle of the Year	Deaths			Number of Deaths per 1,000,000 Inhabitants		
		Suicide	Other Causes	Total	Suicide	Other Causes	Total

1883	167	89	25			
1884	184	96	85			

[1] The figures for Austria up to 1871, although collected by the official registrar, are far from trustworthy. Since 1873 more reliable data have been obtained by the sanitary service. The registrar's figures for 1871 and 1872 have been collected by Dr Neumann Spallart, those for the succeeding years are the figures of the sanitary service. A comparison of the returns from the two official sources shows that the figures of the latter authority are (except in two cases) 30 per cent. greater than the corresponding figures furnished by the former. [2] 1st December 1875. [3] 2,760,586 in 1875.

[4] Population calculated from average annual increase since 1880.

The first feature which appears prominently in connexion with these tables is, as already observed, the small absolute amount of suicide officially reported. There is, however, a general consensus of opinion among those who have made a special study of this branch of vital statistics, to the effect that the number of suicides which actually occur is rather greater than is shown by the official returns. This opinion is based on the known natural repugnance on the part of those concerned to make a declaration that any person found dead committed suicide if his death can be accounted for in any other way. Continental statisticians think that this tendency to "give the benefit of the doubt" in cases of apparent suicide in the manner least likely to give pain to the relatives and friends of the deceased is more strongly operative in England than in other countries, —an opinion which may be fairly considered doubtful when we bear in mind the remarkable difference between the two sets of official figures for Austria. It is not, however, maintained that the number of suicides is much understated, even in England, at any rate of late years. It may be observed that the information on the subject in any country cannot be much relied upon for years previous to 1850, at the earliest, and previous to 1860 for the United Kingdom. Perhaps an exception may be made in favour of the figures for Norway and Sweden. Differences in the mode of determining cases of supposed suicide in different countries make it necessary to be very careful in preparing "international" statistics of suicide. The remarks made by Dr Ogle in the paper already referred to are worth careful attention. He says: "I have been tempted to compare the English figures with those of foreign countries. I have, however, rigidly abstained from doing so. Those who have read the laborious treatise of Morselli on suicide, and have noted how heterogeneous in form and how unequal in numerical efficiency were the materials from different countries with which he was forced to be content, will, I think, agree with me that it is at present more essential that statisticians should look to the accuracy and sufficiency of the returns of their own several countries than that they should indulge in premature comparison." The tables given above are not conceived in a spirit contrary to these judicious observations, but are merely intended to supply indications of the general nature of the phenomenon as met with in different countries. Those who wish to inquire more fully into the matter will find all the available information in the works of Morselli and Legoyt.

It is quite admissible, subject to the above reservations, to point out briefly, and if possible to explain, the leading features brought into relief by the tables. It will be seen that from 1868 to 1876 suicide increased in all countries for which returns were available in both years, not merely in number, but relatively (except Denmark, Prussia, and Scotland) to the population, and the figures for the years subsequent to 1876 do not show any improvement in this respect. It will also be observed that the figures for the United Kingdom and Italy are low, those for Austria, Bavaria, Belgium, and Sweden moderate, those for Prussia, Baden, and France high, and those for Saxony and Denmark very high. Attempts have been made to account for these differences by considerations derived from (1) race, (2) climate, (3) density of population, and other circumstances; but it cannot be said that any satisfactory result has been obtained from these investigations, owing no doubt to the fact that the phenomenon is too minute to furnish numbers large enough for the proper application of the statistical method. Investigations into certain other points have been more successful, such as the relative proportions of the two sexes as regards number of suicides, the relation of the number of suicides to the age scale (see POPULATION) of the population, and also the distribution

of the cases of suicide over the months of the year. Most valuable inquiries have also been made into the distribution of suicides with regard to occupation, with results which appear to show that suicide is more prevalent among the educated than among the illiterate classes. For the suicidal tendency in insanity, see vol. xiii. pp. 105-6.

Sex.—It will have been observed that, apart from fluctuations in particular years, the various countries maintain fairly constant relations to one another as regards number of suicides. The series of numbers in Table I. is fairly regular, in each country usually increasing as the population increases, but in several cases faster. The proportion of female to male suicides is also fairly constant, so far as experience has hitherto gone. Broadly speaking, female suicides are never less than 15 per cent. and never more than 30 of the average annual number of suicides in any country. In England the proportion is high, having during the period 1863-76 averaged 26 per cent. In France the rate is nearly as high, though it appears to have been decreasing of late. In Prussia and most German states the rate is under 20 per cent. For further details reference may be made to Morselli, and for England and Wales to Dr Ogle's paper already mentioned.

Age.—The influence of age on suicide shows considerable regularity in each country from year to year, and a certain degree of similarity in its effects is perceptible in all countries. Morselli gives a number of tables and diagrams, a study of which indicates a variety of interesting features. The observations already made as to the minuteness of the whole phenomenon in relation to the social organism must be particularly borne in mind in drawing conclusions from investigations which involve the breaking up of numbers already small into parts. It is true that, by adding together the corresponding figures for a series of years, fairly large numbers may be obtained, even for those parts of the age scale which, in any single year, yield only one or two cases of suicide, or even occasionally none. But this mode of obtaining an enlarged image of the age scale of suicide must be employed with caution, since there may have been changes in the tendency to suicide, in the age scale, and in the occupations of the people during the period. Dr Ogle has prepared a table (IV.) which gives as correct a representation of the effect of age on suicide in England and Wales as it is possible to furnish. The age scale of suicide in question is also fairly representative of the corresponding age scales of other countries, though in each country slight variations from the typical scale are apparent at different parts of it.

IV. *Average Annual Suicides in England and Wales at successive Age Periods per million Lives, 1858-83* (Ogle).

Age	Rates per Million			Age	Rates per Million		
	Persons	Males	Females		Persons	Males	Females
10	4	4	3	55	251	396	119
15	28	26	30	65	243	394	113
20	47	62	34	75	183	306	85
25	69	99	42	85	116	226	46
35	116	175	62				
45	184	271	103	All ages	72	104	41

It will be seen that, taking both sexes together, the suicide rate rises steadily and rapidly after the tenth year has been passed, attaining its maximum in the period fifty-five to sixty-five years, after which it remains almost stationary for another ten years, when it sinks rapidly. Although no figures are given for any period previous to the tenth year, Dr Ogle mentions that there were actually four cases of suicide of children between the ages of five and ten during the twenty six years observed. Child suicide is apparently of more frequent occurrence on the Continent than in the British Isles. It is important to notice that the age scale of suicide for women is materially different from that for men. If represented by a diagram its curve makes a smaller angle with the base line than the corresponding curve of male suicide. As might be expected from the fact that females become fully developed, both in mind and body, at an earlier period of life than males, the suicide rate for women is relatively very high during the years fifteen to twenty, being in England and several other countries actually higher than that for men. Comparison between different countries in this respect is difficult, but the figures given by Morselli (Table xxvi. in his work) show that during the period in question the number of female suicides increases with great rapidity in all countries. Regarding the suicide of young persons of both sexes, Dr Ogle observes that it is higher than is generally supposed. "Few," he says, "would imagine that one out of every 119 young men who reach the age of 20 dies ultimately by his own hand; yet such is the case." According to Dr Ogle's figures, 1 out of every 312 girls who reach the age of 15 ultimately dies by her own hand.

Influence of Occupation.—The difficulty of investigating the mode in which the suicide rate is affected by differences of occupation is considerable. Dr Ogle has with great labour worked out the figures for males for the six years 1878-83 in England and Wales. He obtained about 9000 cases of the suicide of persons with known occupations; these he compared with the statement of occupations obtained from the census of 1881, taking account of the very considerable variety in the average age of the persons in each occupation. This precaution was necessary in an attempt to ascertain whether the persons engaged in any particular occupation were more liable to suicide than those in other occupations, for the effect due to the occupation would in some cases be entirely obliterated by the effect due to age. The general result of his labours[1] was that the rate for soldiers is enormously in excess of that for any other occupation. It is followed at a considerable distance by innkeepers and other persons having constant access to alcohol,—a fact which certainly suggests that an excessive use of spirits is one of the principal causes of suicide. But another reason for the high rate among soldiers is certainly the fact that they have a ready and effective means of destruction constantly at hand. In like manner the high rate of suicide among medical men, chemists, and druggists may be attributed in part to their familiarity with poisons. Hardly any other general inferences can be drawn without entering on matters of conjecture, except that, excluding the case of clergymen, the rate of those occupations which involve no serious bodily labour is higher than that observed in persons who work chiefly with their hands. It is impossible to make any satisfactory comparison in this respect between England and Wales and other countries, as the divisions of occupations in different countries are not on the same plan. It would be very advantageous if some approach to a common list of occupations could be adopted by all states; but there is little prospect of that being realized for some time to come. It is, however, satisfactorily established that in all countries the suicide rate is higher for the educated than for the uneducated classes.

Season.—May and June are in most countries the months in which most suicides occur; but in some countries, such as Bavaria and Saxony, the maximum is in July. The difference between the warm and cold portions of the year is more marked in female suicides than in male suicides, especially in Italy. This is probably due to the fact that women show a tendency to adopt drowning as a mode of killing themselves, and that there is more shrinking from a plunge into water in cold than in warm weather. The fact that the maximum number of suicides occurs in the hot season, during which, according to Morselli and other Continental statisticians, insanity is more frequent than in the cool portions of the year, has been alleged as a reason for the high suicide rate in May, June, and July.

Modes of Suicide.—The favourite mode of suicide in England is among men hanging and among women drowning,—about one-third of the suicides of each sex being effected in these modes respectively (Morselli, Table xlv.). In Italy, however, the most common mode is by gunshot among men, and after that by drowning, hanging being less usual. A very large number of Italian women drown themselves, the proportion being in some years over 50 per cent. of the total. In Prussia considerably over one-half the male suicides hang themselves, and women also make use of the rope more than in England. The use of poison is more common among English women than among those of Italy and Prussia. Dr Ogle observes that women take less care than men to select painless poisons, nearly 50 per cent. of female suicides by poison in England during the years 1863-82 being effected by means of strychnia, vermin killer, carbolic acid, and oxalic acid, while 60 per cent. of the men employed prussic acid, laudanum, and other comparatively painless poisons. Dr Ogle, Morselli, and other writers have investigated the connexion between the choice of means and the age of suicide. Dr Ogle has also compiled a valuable table relating to method of male suicide in relation to occupation.

The whole subject has been treated exhaustively by Morselli in his *Il Suicidio, Saggio di Statistica Morale Comparata*, Milan, 1879 (Eng. trans., *Suicide: Essay on Comparative Moral Statistics*, London, 1881). Reference may also be made to A. Legoyt's *Le Suicide Ancien et Moderne*, Paris, 1881. This volume contains much interesting historical matter, but is inferior as a statistical work to that of Morselli. It contains, however, a useful bibliography of works on suicide.

Official Information.—Accurate information regarding suicide has for many years been given for all the countries of which mention has been made above in the publications of their respective Governments. For other countries the available statistics are meagre, accurate figures having in many cases only recently been obtained from Finland, Switzerland, Holland, Hungary, Croatia, Spain, and three or four of the States of the American Union. There are no figures for the whole United States, and none of value for any other countries. Such statistics as are in existence for these countries will be found in *Confronti Internationali per gli Anni 1865-83* (Rome, 1884), published by the Italian General Statistical Department. (W. HO.)

SUIDAS, the author of a Greek lexicon. His personal life is totally unknown and even his date is uncertain. He must have lived before Eustathius (12th century), who quotes him repeatedly. Under the heading "Adam" the author of the lexicon gives a brief chronology of the

[1] See *Stat. Jour.*, March 1886, p. 112.

world, ending with the death of the emperor John Zimisces Under "Constantinople" are mentioned the emperors Basil and Constantine, who succeeded John Zimisces in 975 It would thus appear that Suidas lived in the latter part of the 10th century The passages in which Michael Psellus (who lived at the end of the 11th century) are referred to are thought by Kuster to be later interpolations, one of them is wanting in the Paris MSS The lexicon of Suidas is arranged alphabetically, with some slight deviations from the strict alphabetical order It partakes of the nature of a dictionary and encyclopædia, containing not only definitions of words but also short articles on historical, biographical, geographical, and antiquarian subjects It includes numerous quotations from ancient writers, the scholiast on Aristophanes in particular is much used Although the work is uncritical and the value of the articles very unequal, it contains a great deal of important information on ancient history and life It deals with Scriptural as well as pagan subjects, from which we infer that the writer was a Christian Prefixed to the work is a notice stating "the present book is by Suidas, but its arrangement is the work of twelve learned men," and then follow their names

The first edition of Suidas was that by Demetrius Chalcondylas (Milan, 1499), the next by Aldus (Venice, 1514) The chief later editions are those by L Kuster (Cambridge, 1705), by T Gaisford (Oxford, 1834), and by G Bernhardy (Halle, 1834 1853) There is a cheap and convenient edition by Im Bekker (Berlin, 1854)

SULLA (138-78 B C) The life of Lucius Cornelius Sulla makes one of the most important chapters in Roman history Both as a general and as a politician he stands in the foremost rank of the remarkable figures of all time It was by his ability and his force of character that Sulla, who had neither great wealth nor noble ancestry[1] to back him up, pushed himself to the front in early manhood, distinguishing himself in the Jugurthine War in 107 and 106, and being able with a good show of reason to claim the credit of having terminated that troublesome war by capturing Jugurtha himself In these African campaigns Sulla showed that he knew how to win the hearts and confidence of his soldiers, and through his whole subsequent career the secret of his brilliant successes seems to have been the enthusiastic devotion of his troops, whom he continued to hold well in hand, while he let them indulge themselves in plundering and in all manner of licence "Rome's soldiers from Sulla's time," says Sallust (*Cat*, 11), "began to drink, to make love, to have a taste for works of art, to rob temples, and to confound things sacred and profane." From the year 104 to 101 he served again under Marius in the war with the Cimbri and Teutones and fought in the last great battle near Verona, which annihilated the barbarian host Marius, it is said, was jealous of him, and any friendly feeling there may have hitherto been between the two now finally ceased Sulla on his return to Rome lived quietly for some years and took no part in politics What with his genuine love of letters and his love of gay company he was never at a loss for amusement, and he must always have been a particular favourite with fashionable society at Rome In 93 he was elected prætor after a lavish squandering of money, and he delighted the populace with an exhibition of a hundred lions from Africa, from the realm of King Bocchus Next year (92) he went to the East with special authority from the senate to put pressure on the famous Mithradates of Pontus, and make him give back Cappadocia to its petty prince Ariobarzanes, one of Rome's dependants in Asia, whom he had driven out Sulla with a small army soon won a victory over the general of Mithradates, and Rome's client-king was restored An embassy from the Parthians now came to solicit the honour of alliance with Rome, and Sulla was the first Roman who held diplomatic intercourse with that remote people In the year 91, which brought with it the imminent prospect of revolution and of sweeping political change, with the enfranchisement of the Italian peoples, Sulla returned to Rome, and it was generally felt that he was the man to head the conservative and aristocratic party Who was to have the command in the Mithradatic War and be entrusted with the settlement of the East was the question of the day, and the choice lay plainly between Marius and Sulla The rivalry between the two men and their partisans was as bitter as it could possibly be Marius was old, but he had by no means lost his prestige with the popular party

Meanwhile Mithradates and the East were forgotten in the crisis of the Social or Italic War, which broke out in 91 and threatened Rome's very existence The services of both Marius and Sulla were needed, and were given, but Sulla was the more successful, or, at any rate, the more fortunate Of the Italian peoples Rome's old foes the Samnites were the most formidable, these Sulla thoroughly vanquished, and took their chief town, Bovianum But his victories were, after all, followed by the concession of the franchise to the Italian towns and communities generally, though an arrangement which made them vote in separate tribes greatly diminished their political power and became a further source of irritation It was clear that Rome was on the eve of yet further troubles and revolutionary changes Her armies, now recruited from the very scum of the population, had not the loyal and honourable spirit of former days, and cared only for licence and plunder On every side it seemed that public life was demoralized and politics degraded In 88 Sulla was consul, the revolt of Italy was at an end, and again the question came to the front—who was to go to the East and encounter the warlike king of Pontus, against whom war had been declared The tribune Publius Sulpicius Rufus moved that Marius should have the command, there was fearful rioting and bloodshed at Rome at the prompting of the popular leaders, Sulla narrowly escaping to his legions in Campania, whence he marched on Rome, being the first Roman who entered the city at the head of a Roman army Marius now had to fly, and he and his party were crushed for the time

Sulla, leaving things quiet at Rome, quitted Italy in 87 for the East, taking Greece on his way, and for the next four years he was winning victory after victory against the armies of Mithradates and accumulating boundless plunder Athens, the headquarters of the Mithradatic cause, was taken and sacked in 86, and Sulla possessed himself of a library which contained Aristotle's works In the same year at Chæronea, the scene of Philip of Macedon's memorable victory more than two and a half centuries before, and in the year following, at the neighbouring Orchomenus, he scattered like chaff, with hardly any loss to himself, immense hosts of the enemy Crossing the Hellespont in 84 into Asia, he was joined by the troops of Fimbria, who soon deserted their general, a man sent out by the Marian party, now again in the ascendant at Rome The same year peace was concluded with Mithradates on condition that he should resign all his recent conquests, give up all claim to meddle with Rome's Asiatic dependencies, and pay a considerable indemnity In fact the king was to be put back to the position he held before the war, but, as he raised cavils and Sulla's soldiers wanted better terms and more spoil, he had in the end to content himself with being on the same footing as the other princes of Asia,—simply a vassal of Rome.

Sulla returned to Italy in 83, landing at Brundusium,

[1] He belonged to quite a minor branch of the Cornelian gens

having previously informed the senate in an official despatch of the result of his campaigns in Greece and Asia, and announced his presence on Italian ground He complained, too, of the ill-treatment to which his friends and partisans had been subjected during his absence The revolutionary party, specially represented by Cinna, Carbo, and the younger Marius, had massacred them wholesale, confiscated his property, and declared him a public enemy They felt they must resist him to the death, and with numerous bodies of troops scattered throughout Italy, and the support of the newly enfranchised Italians, to whom it was understood that Sulla was bitterly hostile, they counted confidently on success, but on Sulla's advance at the head of his 40,000 veterans many of them lost heart and deserted their leaders, while for the most part the Italians themselves, whom he confirmed in the possession of their new privileges, were won over to his side Only the Samnites, who were as yet without the Roman franchise, remained his enemies, and it seemed as if the old war between Rome and Samnium had to be fought once again Several Roman nobles, among them Cneius Pompeius (Pompey the Great), Metellus Pius, Marcus Crassus, Marcus Lucullus, joined Sulla, and in the following year (82) he won a decisive victory over the younger Marius near Præneste (Palestrina), and then marched straight upon Rome, where again, just before his defeat of Marius, there had been a great massacre of his adherents, in which the famous and learned jurist Mucius Scævola perished Rome was at the same time in extreme peril from the advance of a Samnite army, and was barely saved by Sulla, who, after a bloody and very hard-fought battle, routed the enemy before the walls of Rome With the death of the younger Marius, who killed himself after the surrender of Præneste to one of Sulla's officers, the civil war was at an end and Sulla was master of Rome and of the Roman world Then came, with the object of breaking the neck of the Marian or popular party, the memorable "proscription," when for the first time in Roman history a list of men declared to be outlaws and public enemies was exhibited in the forum, and a reign of terror—a succession of wholesale murders and confiscations throughout Rome and Italy—made the name of Sulla for ever infamous The title of "dictator" was revived after a long period and conferred upon him, Sulla was in fact emperor of Rome, with absolute power over the life and fortunes of every Roman citizen There were of course among them some really honest well-meaning men who looked up to him as the "saviour of society" After celebrating a splendid triumph for the Mithradatic War, and assuming the surname of "Felix" ("Epaphroditus," "Venus's favourite," he styled himself in addressing Greeks), he carried in 80 and 79 his great political reforms (see ROME, vol. xx pp 761-762) Of these the main object was to invest the senate, the thinned ranks of which he had recruited with a number of his own creatures, with full control over the state, over every magistrate and every province, and the mainstay of his political system was to be the military colonies which he had established with grants of land throughout every part of Italy, to the injury and ruin of the old Italian freeholders and farmers, who from this time dwindled away, leaving whole districts waste and desolate Sulla's work had none of the elements of permanence, it was a mere stop-gap purchased at the cost of infinite misery and demoralization

In 79 Sulla resigned his dictatorship and retired to Puteoli, where he died in the following year, probably from the bursting of a blood-vessel, though there is a story that he fell a victim to a particularly loathsome disease similar to that which cut off one of the Herods (Acts xii 23) The half lion, half fox, as his enemies called him, the "Don Juan of politics," to quote Mommsen's happy phrase, the man who carried out a policy of "blood and iron" with a grim humour, amused himself in his last days with actors and actresses, with dabbling in poetry, and completing the *Memoirs* of his strange and eventful life

For Sulla and his times, there is his *Life* by Plutarch, who had his *Memoirs* for one of his authorities, and there are very numerous references to him in Cicero's writings The best and fullest modern account of him is that of Mommsen (vol III, bk IV ch 8, 9) (W J B)

SULLY, MAXIMILIAN DE BÉTHUNE, DUKE OF (1560-1641), French statesman, was born at the château of Rosny near Mantes on 13th December 1560 He derived his early appellation and the title of baron from the place of his birth, and was known as Rosny during the greater part of his life Some one of his numerous enemies pretended that he did not really belong to the illustrious family represented four centuries earlier by the trouvère and warrior Quenes de Béthune, but that his race was derived from Scottish Bethunes of no mark There is, however, no reason for giving any credit to this story Sully was a second son, his elder brother died when but just of age, and even before this his father (if his own account may be trusted) treated Maximilian (so he himself spelt his name, and not Maximilien) as an eldest son He was only eleven years old when his father, who was a Protestant, was presented to Henry of Navarre, and from that time he was more or less inseparably attached to the future king of France He had a narrow escape on St Bartholomew's Day, but he did escape, and when little more than sixteen began to take an active part in the Civil Wars He distinguished himself not a little, especially in the character of engineer In 1583 he married Anne de Courtenay, who, however, died in 1589, and in the intervals of war he lived the life of a country gentleman at Rosny At the battle of Ivry, 1590, he had the good luck, though seriously wounded, to capture Mayenne's standard As soon as Henry's power was established, Sully, who, though by no means always a complaisant or obliging servant, had been uniformly faithful, received his reward in the shape of numerous places, estates, and dignities In 1601 he was made grand-master of the ordnance and in 1606 duke of Sully He was also practically the king's minister of finance during the greater part of his reign After the assassination of his master he makes no further figure in history, though he survived for many years, saw the rise of a far greater minister than himself, and did not die till (less than a year before Richelieu himself died) the 22d of December 1641, at Villebon near Chartres

He had married a second time, and anecdote is not complimentary to his second wife, while his daughter, who married the great duke of Rohan, also had a not unblemished reputation Sully, however, who, though deprived of (and indeed resigning) all control of public affairs after Henry's death, retained great wealth, lived in what was almost a caricature of the stately fashions of the time, and busied himself in the composition of memoirs which are among the most curious in form, and not the least interesting in contents, of the kind He instructed his secretaries to draw the book up in the form of an elaborate address to himself "you then did this", "you said as follows", "as you have been good enough to inform us, the affair went on this wise", and so forth And he not only had the book executed in this extraordinary fashion but had it read out to him Its title is as odd as other things about it and runs thus *Mémoires des Sages et Royales Œconomies d'Estat, domestiques, politiques, et militaires de Henry le Grand, l'Exemplaire des Roys, le Prince des Vertus, des Armes, et des Loix, et le Père en effet de ses Peuples François Et des servitudes utiles, obéissances convenables, et administrations loyales de Maximilian de Béthune, l'un des plus confidans, familiers, et utiles soldats et serviteurs du grand Mars des François Dediées à la France, à tous les bons soldats, et tous peuples François* Two folio volumes were splendidly printed, nominally at Amsterdam, but really under Sully's own eye at his château, in 1634, the other two did not appear till twenty years after his death As his wealth, his im-

perious and grumbling temper, the favour which he had enjoyed and his subsequent loss of it, joined to attract odium, his character and his book were rather roughly handled in his lifetime. Marbault, secretary to Du Plessis Mornay, Sully's chief rival, wrote a very caustic criticism of the *Memoirs*, from which, though it remained in MS. till the 19th century, Tallemant des Réaux, the insatiable scandal monger, compiled a not unamusing but distinctly calumnious article on Sully. Most of the stories it contains may be unhesitatingly disbelieved. At the same time Sully was by no means the ideally wise and good minister that he has not unfrequently been represented as being. He was as faithful as a dog and as surly. He grasped wealth and place to an extent not quite compatible with the idea of pure devotion to his king or his country, and his jealousy of all other ministers and all other favourites was extravagant and unceasing. Still there is no doubt that he was an excellent man of business, that, if not exactly what would be now called an incorruptible minister, he made no gains not sanctioned by the customs of the time, that he was inexorable in interfering with peculation and malversation on the part of others, that he opposed the ruinous personal expenditure which was the bane of almost all European monarchies in his day, and that he did much both as a man of war and as a man of peace to make France strong, united, and happy. His literary power, moreover, was far from small. Although the fantastic form of his *Memoirs*, after being diverting for a time, grows not a little wearisome, they have phrases and passages of great vivacity, which it is reasonable to attribute to Sully himself rather than to his spokesmen, and they show much grasp of administrative business.

The arrangement of the *Memoirs* so shocked the 18th century that in 1745 the abbé de l'Écluse re-edited or rather rewrote them in the ordinary form of narrative. This text has of course no interest; the proper version with the commentary of Marbault may be found in the collection of Michaud and Poujoulat (vols. xvi. and xvii.)

SULMONA, or SOLMONA, a city of Italy, in the province of Aquila (Abruzzo Ulteriore), now reached by a branch line from the railway between Pescara and Aquila, lies, at a height of 1575 feet above the sea, at the junction of the Vella with the Gizio (a tributary of the Pescara), which supplies water-power to its paper mills, fulling-mills, copper-works, &c. Besides its cathedral (S. Panfilo), rebuilt by Bishop Walther of Ocre (Frederick II.'s grand chancellor) in 1119, and several times remodelled in the 15th and 16th centuries, Sulmona has in Santa Maria della Tomba a good example of pure Gothic, and in Corpus Domini a striking instance of the vagaries of Gothic in its decay. The communal buildings are half Gothic, half Renaissance. A statue of Ovid, the most celebrated native of the city (which also gave birth to Innocent VII.), stands in front of the cancellaria. In the vicinity of the town is Monte Morrone, where Celestine V. lived as a hermit and founded a monastery of "Celestines," which remained till 1870, when it was transformed into a penitentiary. The population of Sulmona was 12,594 in 1861 and 14,171 in 1881 (commune, 17,601).

Sulmo, a city of the Peligni, is first mentioned during the Second Punic War (211 B.C.). It became a Roman colony probably in the reign of Augustus, and as a municipium it continued to flourish throughout the empire. Charles V. erected it into a principality, which he bestowed on Charles Lannoy of "Pavia" celebrity. It ultimately passed to the Conno and Borghese families. The bishopric is known as that of Valva and Sulmona.

SULPHUR.[1] The sulphur minerals, which are very numerous and varied, arrange themselves under three heads,—(1) *metallic sulphates*, of which hydrated sulphate of lime, $CaSO_4\ 2H_2O$, gypsum, is the most abundant; (2) *metallic sulphides*, a numerous family, including the majority of metallic ores, of which, however, only iron pyrites serves as a source for sulphur; (3) *elementary sulphur*. In the organic world we meet with sulphur everywhere, this element forming an essential (though quantitatively subordinate) component of the albumenoids, a class of compounds contained in all vegetable and animal structures. Of organic materials rich in sulphur we may name animal hair (containing about 4 per cent.) and the essential oils of the onion, garlic, and mustard.

[1] This chemical element has already been treated in its scientific aspects under CHEMISTRY (vol. v. p. 498 *sq.*). The present article is intended to supplement what is there given, in the direction chiefly of practical applications.

Elementary Sulphur.

This occurs as a mineral chiefly in the Upper Miocene deposits and in the Flotz, associated in general with gypsum, massive limestone, and marl. Commercially important deposits are found in Sicily (provinces of Caltanissetta, Girgenti, Catania), Italy (Latera and Scrofano, province of Rome), Spain (Teruel and Arcos), France (dept. Vaucluse), Transylvania, Poland (Swoszowice near Cracow), and Germany (Luneburg, in Hanover). The exhalations of volcanoes include, as a rule, sulphurous acid, SO_2, and sulphuretted hydrogen, H_2S, which two gases, if moist, readily decompose each other into water and sulphur,—a circumstance which accounts for the constant occurrence of sulphur in all volcanic districts. Mt Puracé in Colombia wears a cap of sulphur (derived from its own crater) which accumulates at the rate of about 2 feet per annum,—its superficial area amounting to 1435 square yards. The solfatara at Bahara Saphinque on the Red Sea is said to yield 600 tons of sulphur annually. The molten sulphur discharged from the crater of the Alaghez in the Armenian highlands forms solid excrescences, which the natives dislodge from their inaccessible positions by means of rifle-shots. A sulphur deposit near the Borax Lake in California is estimated to contain 20,000 tons. Most of the sulphur Sicilian
or brimstone of commerce comes from the rich fields of sulphur
Sicily, where in 1884 the annual production had almost reached 400,000 tons. The mode of mining there adopted is by a network of horizontal galleries (tunnels) driven through the deposit; the solid squares thus marked off are hewn out, a central pillar being left to support the roof. The total excavation is generally 100 feet high and from 25 to 50 wide; not unfrequently the whole collapses. Down to a comparatively recent date all the work used to be done by hand, boys of eight to ten years of age being employed to carry the ore to the shaft and thence to the surface; only where a mine has reached a depth of 325 feet or more is water-power, if available, resorted to. Since 1868, however, the ore at Grotta Calda at least has been raised by properly constructed shafts with the help of steam-power, and this system is spreading.

The Sicilian ores are customarily classified as follows:—

	Per 100 parts of ore Sulphur present.	Per 100 parts of ore Sulphur recovered.
Richest ores	30 40	20 25
Rich ores	25 30	15 20
Ordinary	20 25	10 15

The poor yield of actual sulphur is explained by the rather primitive method used for its extraction. A semicircular or semi-elliptical pit (*calcarone*) about 33 feet in diameter and 8 deep is dug into the slope of a hill, and the sides are coated with a wall of stone. The sole consists of two halves slanting against each other, the line of intersection forming a descending gutter which runs to the outlet. This outlet having been closed by small stones and sulphate of lime cement, the pit is filled with sulphur ore, which is heaped up considerably beyond the edge of the pit and covered with a layer of burnt out ore. In building up the heap a number of narrow vertical passages are left to afford a draught for the fire. The ore is kindled from above and the fire so regulated (by making or unmaking air-holes in the covering) that, by the heat produced by the combustion of the least sufficient quantity of sulphur, the rest is liquefied. The molten sulphur accumulates on the sole, whence it is from time to time run out into a square stone receptacle, from which it is ladled into damp poplar-wood moulds and so brought into the shape of truncated cones weighing 110 to 130 lb each. These cakes are sent out into commerce. A calcarone with a capacity of 28,256 cubic feet burns for about two months, and yields about 200 tons of sulphur. The immense volumes of sulphurous acid evolved give rise to many complaints; all the minor pits suspend work during the summer to avoid destruction of the crops. A calcarone that is to be used all the year round must be at least 220 yards from any inhabited place and 110 from any field under cultivation.

The yield of sulphur, as seen from the table given above, is miserably small, but the scarcity of fuel in Sicily almost prohibits the introduction of any more rational method. As sulphur fuses at 114° C., high pressure steam at once suggests itself as a suitable medium of heating. In the sulphur works of Latera, in the province of Rome, the following apparatus (constructed by Gritti) is

being used with success. A vertical truncated perforated cone of thick sheet iron serves for the reception of the ore. This cone is enclosed in a similar cone of iron, which terminates in a detachable deep iron basin below, and is provided with a tightly fitting lid. All the joints in this outer shell are steam tight. The inner cone having been charged and the lid secured, steam of sufficient pressure to ensure a temperature of from 125° to 135° C. is blown into the apparatus, which soon causes the sulphur to melt and collect in the basin below. After from 30 to 50 minutes, reckoning from the time when the above temperature is reached, the operation is completed. The steam is then turned off and the sulphur made to run from the basin into a receptacle beside the apparatus, to be cast into sticks or cakes. The iron basin is then detached, and by turning aside an iron damper which held the ore in its place the exhausted ore is made to drop into a pit. Each charge of ore amounts to about from $25\frac{1}{2}$ to $26\frac{1}{2}$ cwts., containing about 385 lb of sulphur. Of this some 360 lb are recovered as saleable sulphur, at the expense of about 286 lb of oak wood as fuel.

Extraction R. E. Bollmann in 1867 proposed to extract the sulphur by means of bisulphide of carbon. The process, after having been tried at Bagnoli near Naples and given up as hopeless, was introduced in 1873 in Swoszowice near Cracow under the guidance of Winkler and has proved a success. The apparatus is constructed so that the bisulphide used in the process of extraction is recovered by distillation; the loss of bisulphide amounts only to one-half per cent., sometimes to less, and the sulphur produced is very pure. But by far the greater part of the purer qualities of commercial sulphur is produced from Sicilian calcarone sulphur by distillation, which removes the 3 per cent. or so of earthy impurities contained in it. The following apparatus (invented originally by Michel of Marseilles and improved subsequently by others) enables the manufacturer to produce either of two forms of "refined" sulphur which commerce demands. It consists of a stone-built chamber of about 2825 cubic feet capacity, which communicates directly with two slightly slanting tubular retorts of iron, each of which holds about 660 lb of sulphur. The retorts are charged with molten sulphur from an upper reservoir, which is kept at the requisite temperature by means of the lost heat of the retort fires. The chamber has a safety valve at the top of its vault, which is so balanced that the least surplus pressure from within sends it up. The first puff of sulphur vapour which enters the chamber takes fire and converts the air of the chamber into a mixture of nitrogen and sulphurous acid. The next following instalments of vapour, getting diffused throughout a large mass of relatively cold gas, condense into a kind of "snow," known in commerce and valued as "flowers of sulphur" (*flores sulphuris*). By conducting the distillation slowly, so that the temperature within the chamber remains at a sufficiently low degree, it is possible to obtain the whole of the product in the form of "flowers." If compact ("roll") sulphur is wanted the distillation is made to go on at the quickest admissible rate. The temperature of the interior of the chamber soon rises to more than the fusing-point of sulphur (114° C.), and the distillate accumulates at the bottom as a liquid, which is tapped off from time to time to be cast into the customary form of rods of about $1\frac{1}{2}$ inches diameter.

In some places sulphur is extracted from iron pyrites by one of two methods. The pyrites is subjected to dry distillation from out of iron or fire clay tubular retorts at a bright red heat. One-third of the sulphur is volatilized—$3FeS_2 = Fe_3S_4 + S_2$—and obtained as a distillate. The second method is analogous to the calcarone method of liquation: the ore is placed in a lime kiln like furnace over a mass of kindled fuel to start a partial combustion of the mineral, and the process is so regulated that, by the heat generated, the unburnt part is decomposed with elimination of sulphur, which collects in the molten state on an inverted roof shaped sole below the furnace and is thence conducted into a cistern. Such pyrites sulphur is usually contaminated with arsenic, and consequently is of less value than Sicilian sulphur, which is characteristically free from this impurity.

Milk of sulphur The substance known as "milk of sulphur" (*lac sulphuris*) is very finely divided sulphur produced by the following, or some analogous, chemical process. One part of quicklime is slaked by means of 6 parts of water, and the paste produced diluted with 24 parts of water; 2.3 parts of flowers of sulphur are added, and the whole is boiled for about an hour or longer, when the sulphur dissolves,—

$$3CaO + 12S = 2CaS_5 + CaS_2O_3$$

The mixed solution of pentasulphide and thiosulphate of calcium thus produced is clarified, diluted more largely in a tub, and then mixed with enough of pure dilute hydrochloric acid to produce a feebly alkaline mixture; this shows that only the bulk of the pentasulphide is decomposed,—$CaS_5 + 2HCl = CaCl_2 + H_2S + (4S$ of precipitated sulphur$)$. The addition of more acid would produce an additional supply of sulphur (by the action of the $H_2S_2O_3$ on the dissolved H_2S), but this thiosulphate sulphur is yellow and compact, while the CaS_5 part has the desired qualities, forming an extremely fine, almost white, powder. The precipitate is washed, collected, and dried at a very moderate heat. It is used as a medicine. If sulphuric acid is used instead of hydrochloric acid the preparation is apt to be contaminated with hydrated sulphate of lime. In the United Kingdom, indeed, precipitated sulphate of lime used to be added intentionally to produce what the public had got accustomed to; but this practice has been rightly stopped by the authorities.

During the year 1875 the production of sulphur in Europe is stated to have been as follows:— Production and uses

	Tons
Italy	360,000
Spain	4,000
Austria Hungary	3,750
German empire (including 5000 tons of regenerated[1] sulphur)	14,500
Belgium	450
Total	382,700

By far the greater part of all the sulphur produced in Sicily and elsewhere is used for the manufacture of sulphuric acid. Subjoined is an enumeration of some other applications. (1) The manufacture of gunpowder (see vol. xi. p. 320). (2) The taking of casts. (3) The making of cements: (*a*) a mixture of molten sulphur and ferric oxide is used to cement the isolating bells to telegraph posts; (*b*) a mixture of iron filings (100), flowers of sulphur (3 to 20), and sal ammoniac (3 to 5) made into paste with water is used to cement iron bars (fences, &c.) into stone sockets; (*c*) a mixture of molten sulphur with powdered quartz or glass has been recommended as an acid proof material for sulphuric acid chambers; (*d*) a mixture produced by the incorporation of powdered quartz and colouring matters, such as vermilion, &c., with molten sulphur is employed for ornamental articles. (4) The vulcanization of india-rubber (see vol. xii. p. 840 *sq.*). (5) Dusting vine plants with flowers of sulphur is said to keep off the fungus *Oidium Tuckeri*, which has caused such devastation in the vineyards in France and elsewhere.

Sulphur Compounds

Sulphuretted hydrogen, H_2S (see CHEMISTRY, vol. v. p. 499 *sq.*), Sulphuretted hydrogen
is used largely as such, or as sulphide of ammonium, $(NH_4)_2S = 2NH_3 + H_2S$, for the detection, discrimination, and separation of metals. To give an example: the least quantity of lead dissolved in water as (say) nitrate can be detected by the addition of sulphuretted hydrogen, which brings down the lead as a black precipitate of sulphide of lead,—$Pb(NO_3)_2 + H_2S = PbS + 2HNO_3$. The presence of a moderate quantity of mineral acid in the original solution does not interfere with the test. What we said of solution of salts of lead holds substantially of those of the following groups of metals. The formulæ and the colours of the sulphides are given in brackets. A. Lead (black, PbS), silver (black, Ag_2S), mercury as mercurous or mercuric salt (black, $HgS + Hg$ or HgS respectively), copper (greenish black, CuS), bismuth (brown, Bi_2S_3), cadmium (yellow, CdS). B. Arsenic (yellow, As_2S_3), antimony (orange-red, Sb_2S_3), tin as stannic salt (yellow, SnS_2). The sulphides A are insoluble, the sulphides B are soluble in sulphide of ammonium solution, and the latter, from this solution, can be reprecipitated by acidification with dilute sulphuric or hydrochloric acid. The brown SnS precipitated from stannous salts is insoluble in the (colourless) solution of $(NH_4)_2S$, but soluble in the yellow solution of the polysulphide $(NH_4)_2S_2$, as SnS_2. C. The following metals are not precipitated from their salt solutions if these are acidified sufficiently by added mineral acid, but they are precipitated from their neutral or alkaline solutions by sulphide of ammonium:—iron (black, FeS), nickel (black, NiS), cobalt (black, CoS), manganese (flesh coloured, MnS), zinc (white, ZnS). Aluminium and chromium, given as salts of their oxides, R_2O_3, are precipitated by sulphide of ammonium as hydrated oxides ($Al_2O_3\,xH_2O$, colourless; $Cr_2O_3\,xH_2O$, green or violet). The reagent acts on these as ammonia, NH_3, the H_2S being liberated, and behaves in a similar way to acid solutions of certain salts, *e.g.*, the phosphates, of the following group D, these salts, *e.g.*, $Ca_3P_2O_8$, being precipitated as such. The ordinary salts of group D (barium, strontium, calcium, magnesium), and the salts of the alkali metals E (potassium, sodium, &c.) generally, give no precipitate with either sulphuretted hydrogen or sulphide of ammonium. It is easy to translate what we have stated into a method for the separation of groups A, B, C (D and E), from one another.

Of the three chlorides treated of in CHEMISTRY (vol. v. p. 501) Chlorides
only the lowest, S_2Cl_2, is of industrial importance. It is prepared by passing perfectly dry chlorine gas over heated sulphur contained in a retort, the retort being connected with a condenser constructed so that the uncondensed vapours are led away into the chimney. The two elements unite readily, and chloride of sulphur, S_2Cl_2, distils over, contaminated, however, by more or less of surplus chlorine present as higher chlorides. To remove (or decompose) these the crude product is subjected to fractional distillation; the thermometer rises rapidly and soon becomes constant (at about 136° under 758 mm. pressure). What afterwards distils over, at the constant boiling point, is collected as pure S_2Cl_2,—a yellowish red liquid of 1.68 sp. gr. at 16°.7 C. and 1.7055 at 0° (Kopp), which emits fumes of hydrochloric acid in moist air. Its smell is charac-

[1] See SODIUM, "Le Blanc process for making soda ash," p. 243 above.

teristic and unpleasant Chloride of sulphur is decomposed by water, alcohol, ether (see CHEMISTRY), and benzol and bisulphide of carbon mix with it in all proportions without decomposition A mixture of 100 parts of bisulphide of carbon and some 2 5 of chloride of sulphur is used for the vulcanization of (chiefly sheet) india-rubber The mixture is readily imbibed by the rubber, which when allowed to dry (at from 22° to 25° C) gives up the bisulphide of carbon and the chlorine of the reagent, the latter as HCl, but retains its sulphur in a state of chemical combination

Sulphurous acid. The gas SO_2 (see CHEMISTRY, vol v p 501), produced extempore by the combustion of sulphur, is used for the bleaching of silk, wool, straw, and wicker work, also for the disinfection of rooms and of wine casks (to prevent acetous fermentation) A solution of the gas in water is manufactured industrially, for use chiefly in the manufacture of sugar It is added to the beetroot or cane juice to prevent its fermentation while awaiting concentration A solution of "bisulphite of lime" (produced by saturating milk of lime with sulphurous acid gas) is much used as an antiseptic generally Liquefied sulphur dioxide has found an application as a frigorific for the manufacture of ice The apparatus used is so constructed that the volatilized sulphur dioxide is all caught and recondensed Sulphurous acid when required as such or for the making of sulphites is always produced, even industrially, from oil of vitriol, by reduction with either sulphur or charcoal In the heat the reactions are $2SO_3+S=3SO_2$ and $2SO_3+C=CO_2+2SO_2$ respectively, and either can be (and is) executed practically in cast iron vessels The presence of carbonic acid in the gas produced by the charcoal process does not interfere with the preparation of sulphites

Thiosulphates. The soda salt $Na_2S_2O_3+5H_2O$, known commercially as hyposulphite of soda, is used industrially for chiefly two purposes, namely, (1) as a solvent for chloride of silver in photography (see PHOTOGRAPHY),—$AgCl+Na_2S_2O_3=NaCl+AgNaS_2O_3$,—and (2) as an "antichlor" in paper making, to destroy the remnants of chlorine in bleached paper pulp To understand its action we need only know that chlorine and water in such cases act like oxygen,—$Cl_2+H_2O=2HCl+O$, every $4\times O$ thus produced converts one S_2O_2 of $Na_2OS_2O_2$ into $2SO_3$ of sulphuric acid For the preparation of this salt a great many methods have been invented The simplest to explain is the treatment of a solution of normal sulphite of sodium with sulphur,—$SO_3Na_2+S=S_2O_3Na_2$ Instead of adding free sulphur, Liebig prepares a solution of polysulphide of sodium (by dissolving sulphur in caustic soda ley) and adds it to the sulphite The surplus sulphur combines with the sulphite, besides, the polysulphide contains thiosulphate from the first Another method is to pass sulphurous acid through a solution of sulphide of sodium Here, by first intention, if we may say so, sulphite of sodium and H_2S are produced, but the H_2S and the excess of SO_2 give water and sulphur, and two thirds of this sulphur unite with the sulphite first formed into thiosulphate The crude sulphide of calcium, which is produced so largely in the Le Blanc process (see SODIUM, *supra*, p 243), when exposed to the air gets oxidized, with formation of calcium thiosulphate, which can be extracted by means of water and converted into sodium salt by double decomposition with carbonate or sulphate of soda Pure thiosulphate of soda forms large transparent monoclinic prisms, which lose no water on exposure to ordinary air in the cold At about 48° C they fuse into a liquid, which may remain liquid on cooling, but solidifies suddenly when a fragment of the solid salt is dropped in 100 parts of water dissolve

at 16°	25°	35°	45° C
65	75	89	109 parts of the salt (Mulder)

The solution is not subject to oxidation in the air

Sulphuric acid. The anhydride SO_3 is used largely in the manufacture of tar colours Oil of vitriol is decomposed by dropping it on a mass of platinum scrap kept at a bright red heat within a fireclay retort, —$SO_4H_2=H_2O+SO_2+\frac{1}{2}O_2$, and, after removing the water—the bulk by partial condensation and the rest by means of vitriol—the sulphur dioxide and the oxygen are made to recombine by passing them over platinized asbestos at a dull red heat The fumes of SO_3 formed are condensed in a dry receiver by application of cold from without (Winkler's process)

The fact that finely divided platinum, in virtue of its power of condensing oxygen, induces the union of SO_2 and $\frac{1}{2}O_2$ into SO_3 has been known for a long time, but all attempts to utilize the reaction for the production of sulphuric acid from a mixture of sulphur dioxide, air, and nitrogen produced by the combustion of sulphur or pyrites in air have failed The platinum acts too feebly in the presence of the unavoidably large mass of nitrogen, and soon loses its efficacy altogether owing to the accumulation on it of particles of incombustible matter from the kiln gases Oxide of chromium, Cr_2O_3, and oxide of iron, Fe_2O_3, act like platinum, through transitory formation of the respective sulphates—the gases produced in pyrites kilns include a considerable quantity of ready-made SO_3 —but they also are not available practically for the making of sulphuric acid In short, all attempts to produce this reagent otherwise than by means of the old Nordhausen or the chamber process have so far been unqualified failures industrially In regard to the chamber process we may add a few notes to what has been said under CHEMISTRY (vol v p 503 *sq*) As stated in that article, nitrous acid, N_2O_3, when brought into contact with sufficiently strong vitriol unites with it, giving rise to bodies similar to chamber crystals,—

Chamber process production

$$N_2O_3+H_2O+2SO_3=2SO_2{}^{OH}_{NO_2}\,,$$

or, what comes practically to the same,

$$N_2O_3+SO_3(\text{out of the vitriol})=SO_2{}^{NO_2}_{NO_2}$$

In the presence of sufficient water this union does not take place, because the water causes the product to break up as shown by the equation if read from right to left These facts explain why a stronger acid than one containing some 60 per cent or so of real H_2SO_4 cannot be produced directly in the chamber This inconvenience has led, in the hands of Gay-Lussac, to an important improvement on the original process He inserts between the chamber outlet and the chimney a tower made of acid proof stone and filled with pieces of coke, over which concentrated oil of vitriol is made to trickle down while the chamber gases ascend through the tower on their way to the chimney The vitriol absorbs all or most of the N_2O_3, which would otherwise be lost But the practical reliberation of the N_2O_3 was beset with very great difficulties, which have been fully overcome only by a more recent invention of Glover's He places between the kiln and the entrance side of the chamber a tower similar in construction to Gay Lussac's, which the kiln gases have to traverse before they get into the latter Through the tower he runs at the same time a stream of nitrated (Gay Lussac) acid and one of ordinary chamber acid The latter acts on the nitrated acid as water, at least it virtually sets free the combined nitrous acid, so that it is reduced by the sulphurous acid coming from the kiln to nitric oxide, which travels into the chamber with the rest of the gases to do duty there in the well-known manner As the kiln gases are very hot, a considerable quantity of the water which goes through a Glover tower (as chamber acid) is volatilized and thus made to supply part of the steam necessary for the process The Glover tower, besides fulfilling its primary object, serves to concentrate part of the chamber acid and to supply part of the necessary steam without expense for fuel The expenditure of nitrate of soda, which before the introduction of the two towers used to amount to from 8 to 13 parts per 100 of sulphur burned, has been reduced to from 3 5 to 6 5 The actual loss of nitrous acid of course is the less, *cæteris paribus*, the larger the chamber, and (for a given chamber) the greater the care with which the process is conducted But even under the most skilful management more nitrous acid is lost than can be accounted for by the unavoidable imperfections in the apparatus and in the mode of working them From the investigations of Weber and of Frémy it appears that, in the presence of relatively much water more especially, part of the nitrous acid suffers reduction, not to nitric, but to nitrous oxide, N_2O, which, being unsusceptible of direct oxidation, is lost for the process

Production of strong acid. For a great many purposes (*e g*, the manufacture of "superphosphate" from bones or mineral phosphate of lime) the 60 to 64 per cent acid which comes out of the chamber can be used as it is, but it is not strong enough for all purposes In the production of stronger (from chamber) acid the first step always is to run the acid into long, very shallow lead pans and to simply boil it down in these, either by the application of heat from below, in which case the bottoms of the pans must be protected by making them rest on plates of iron, or by enclosing the pans in a vault and causing the hot gases of a furnace fire to strike along the surface of the acid The result in either case is that, while more and more water goes away as steam, the residual acid of course gets stronger and stronger But with the strength the boiling point rises, and, as necessary consequences, the extent to which the acid attacks the lead (with formation of sulphate and sulphurous acid) and the danger of melting down the pans by local overheating become greater and greater When the acid has come up to about from 78 to 80 per cent (corresponding to a specific gravity of 1 7 after cooling), it is not safe to push the concentration any further, quite apart from the fact that an acid of 80 per cent when boiled down emits a very appreciable proportion of acid along with the volatilized water An acid of 1 7 indeed is amply strong enough for a variety of applications, such as, for instance, the conversion of salt into sulphate If a stronger acid is wanted the concentration must be continued in glass or platinum retorts

Vitriol maker's glass retort. The vitriol maker's glass retort, as a rule, consists of two detachable parts, namely, a pear shaped body about $3\frac{1}{2}$ feet high and nearly 2 feet in diameter, and a glass alembic whose wider end fits the mouth of the pear, while its narrower outlet end points downwards and terminates within a slightly slanting lead pipe, which conveys the distillate to a leaden tank The retort rests on a layer of sand contained in a closely fitting iron basin, and the lateral space between the two is filled completely with sand The iron basin is suspended within a furnace in such a way that only it, and not any part of the retort, is touched directly by the flame As a rule, some twelve retorts stand side by side, each in its own

sandbath, and are heated by the same fire As the temperature of the boiling liquid and of the vapour rises at the end to beyond 300° C, a sudden draught of cold air might cause rupture of a retort, the apparatus is therefore placed in a special room accessible only through double doors, and the inner door is not permitted to be opened before the outer has been shut The acid, as it is boiling down, gets stronger and stronger, because, although the vapour is very strongly acid from the first, its percentage p' of real H_2SO_4 at any given stage is less than the value p, which obtains in the boiling liquid as it is at the time p' at a given barometric pressure is a fixed function of p only, and increases as p increases, the difference $p-p'$ accordingly gets less and less It becomes nil, not when the acid has become pure H_2SO_4, but when it has come up to the composition $12SO_3+13H_2O$ (Marignac) This particular hydrate only boils without change of composition, even pure H_2SO_4 when distilled, by giving up more than $1SO_3$ for $1H_2O$, becomes reduced to that hydrate $12SO_3+13HO$, which then boils without further change of composition A stronger acid than "Marignac," as we may call it, cannot be produced by the concentration of weaker acid, and even its production (from 1 7 acid) involves a very considerable loss of acid as distillate Hence practically the process is stopped when the acid in the retorts has come up to some 96 per cent of H_2SO_4, which is ascertained by the specific gravity of the last runnings being at a certain value As soon as this point is reached the retorts are allowed to cool till the contents can be withdrawn with safety by means of lead siphons into glass carboys This, however, means a considerable loss of time and fuel, besides, the process of distilling from out of glass vessels is not free from danger, and for these reasons it is preferred in many establishments to concentrate the pan acid in large platinum stills, although these are extremely expensive The great advantage of the platinum still is that it admits of continuous working, while pan acid (containing say 1 lb of water per N lb of full strength—96 per cent or so—acid) runs in, and a far weaker acid (containing for the same period of time 1 lb of water and n lb of full strength acid) is distilling over, the balance $N-n$ lb of finished acid is being withdrawn by means of a platinum siphon The outer limb of the siphon in its middle portion divides into a system of four narrower tubes and is cooled down by means of a cold water jacket surrounding it, so that the acid can be run directly into carboys

Platinum retort. The platinum retort in its latest form has a large undulating bottom made of strong metal, on which a rapidly converging low body joins, made of thinner metal because it is not so directly exposed to the flame Along with this still a flat platinum pan is used with an undulating bottom similar to that of the still for the preliminary concentration of the acid As platinum is not liable to fuse or be attacked by any strength of boiling acid, a relatively small platinum pan does as much work as a far larger one made of lead

Sulphates

Several of these are treated of under the heads of the respective bases Thus, for the sulphates of ammonia, see NITROGEN, vol XVII p 515 *sq*, for POTASSIUM and SODIUM, see these articles, for calcium, see LIME (vol XIV p 648) and GYPSUM (vol XI p 351), for barium, see BARYTES (vol III p 406), for magnesium, see EPSOM SALTS (vol VIII p 496) and MAGNESIUM (vol XV p 217), and for iron, see COPPERAS (vol VI p 352)

Sulphate of alumina. Sulphate of aluminium, $Al_2(SO_4)_3+18H_2O$, the active ingredient of ALUM (vol I p 643), is now being produced industrially in a state of perfect freedom from iron, and is more and more taking the place of alum Paper makers, at least, no longer use anything else for the production of alumina soap, which in machine made paper serves as the principal ingredient of the size The crude salt is easily produced by treatment of relatively pure bauxite (native hydrated alumina) or china clay with chamber acid at a suitable temperature The resulting mass is dissolved in water, the undissolved matter (silica, &c) allowed to settle, the clear liquor drawn off, and from it an apology for what is wanted is obtained by evaporation to a small volume and allowing to crystallize But the salt thus obtained is always contaminated with a variety of foreign sulphates, including sulphate of iron, and this last-named impurity, for the majority of applications, cannot be suffered to remain One of the best methods for its removal, if not the best, is that discovered by Semper and Fahlberg the solution, which must contain all its iron as ferric salt and contain somewhat less than the normal proportion of sulphuric acid, is digested with hydrated binoxide of lead In the course of about a week all the iron is completely precipitated The better qualities of sulphate of alumina nowadays have at most only a few thousandths per cent of iron

Sulphate of copper. Sulphate of copper (blue vitriol) is made technically in chiefly two ways One method is to heat metallic copper to redness in air until it is almost completely oxidized, and to dissolve the oxide by means of dilute sulphuric acid The Cu_2O present behaves like a mixture of metal and CuO Another process starts from the subsulphide Cu_2S (produced metallurgically as "mat," or perhaps expressly from its elements), and converts this into sulphate and oxide by careful roasting The product is dissolved in dilute sulphuric acid Large quantities of blue vitriol are produced incidentally in the "parting" of auriferous silver (see GOLD, vol X p 749) by means of oil of vitriol Sulphate of copper crystallizes from its aqueous solution in large transparent blue crystals of the triclinic system, their composition is $CuSO_4 5H_2O$ The crystals are stable in the air At 100° C they lose $4H_2O$, the last H_2O requiring a temperature of 200° C for its expulsion The anhydrous salt is dirty white, it readily reunites with water, and consequently is available as a dehydrating agent, for instance, for the preparation of absolute alcohol from spirit of wine 100 parts of water dissolve

at	0°	10°	20°	50°	100° C
	31 6	37 0	42 3	65 8	203 3 parts of crystallized salt (Poggiale)

The salt is insoluble in alcohol Blue vitriol is used largely in electrotyping and for many other purposes

Analysis. Subjoined are two general tests for sulphur (1) All sulphur compounds when brought in contact at a red heat with a mixture of nitre and carbonate of soda (or some other equivalent alkaline oxidizing mixture) are changed so that the sulphur assumes the form of alkaline sulphate, which can be extracted by means of water From the (filtered) solution the SO_3 is precipitated by addition of chloride of barium as $BaSO_4$,—a white powdery precipitate characteristically insoluble in water and in dilute acids (2) Any non-volatile sulphur compound, when heated on charcoal in a reducing flame with carbonate of soda, yields sulphide of sodium ("hepar"), which, when moistened with water on a silver coin, produces a black stain of metallic sulphide (Compare SELENIUM vol XXI pp 631-632) (W D)

SULPICIUS SEVERUS See SEVERUS

SULTÁNPUR, or SULTANPOOR, a district of British India, in the Rái Bareli (Roy Bareilly) division of Oudh, under the jurisdiction of the lieutenant-governor of the North-Western Provinces, lying between 26° 39′ and 27° 58′ N lat and 81° 36′ and 82° 44′ E long With an area of 1707 square miles, it is bounded on the N by Faizábád, on the E by Jaunpur, on the S by Partábgarh, and on the W by Rái Bareli The surface of the district is generally level, being broken only by ravines in the neighbourhood of the rivers by which its drainage is effected The central portion of the district is highly cultivated, while in the south are widespread and plains and swampy jhils and marshes The principal river is the Gumti, which passes through the centre of Sultánpur and affords a valuable highway for commerce Minor streams are the Kándu, Píli, Tengha, and Nandhia, the last two being of some importance, as their channels are deep, though narrow, and form the outlet for the superfluous water of the extensive series of jhils There are no forests in the district, the only tree-covered tracts being stunted *dhák* jungles used for fuel Wild animals are very few, chiefly wolves, nylghau, and wild hog There are some good roads in the district, chief of which is the imperial high road from Faizábád to Allahábád, which intersects it from north to south The Oudh and Rohilkhand Railway traverses the district for a few miles in the extreme east The climate is considered mild, temperate, and healthy, the average annual rainfall is about 46 inches

The population, according to the census of 1881, was 957,912 (males 475,125, females 482,787), of whom 856,329 were Hindus and 101,524 Mohammedans The only town with a population exceeding 5000 is Sultánpur, the administrative headquarters of the district, which is situated on the right bank of the Gumti, and in 1881 contained 9374 inhabitants Of the total area 571,795 acres were returned as cultivated in 1884 85 and 368,911 as cultivable, the total area under crops in the same year was 672,058 acres, wheat and rice being the principal products The trade of the district deals principally with grain, cotton, molasses, and native cloth, and its manufactures—which, however, are unimportant—comprise coarse cotton cloth, brass vessels and other metal work, sugar, and indigo The only incident worthy of note in the history of the district since the British annexation of Oudh is the revolt of the native troops stationed at Sultánpur during the mutiny The troops rose in rebellion on 9th June 1857, and, after firing on and murdering two of their officers, sacked the station Upon the restoration of order Sultánpur cantonment was strengthened by a detachment of British troops, but in 1861 it was entirely abandoned as a military station

SULU ISLANDS See PHILIPPINES, vol XVIII p 752

SUMACH See LEATHER, vol XIV p 382

Plate IX. SUMATRA, in Malay called *Pulu Percha* or *Indalas*, is one of the largest and most important islands of the East Indian Archipelago. It stretches from north-west to south-east for a distance of 1047 miles,—Tandjong Batu, the northmost point, being situated in 5° 40′ N. lat. and the southmost in 5° 59′ S. lat. The greatest breadth is about 230 miles. In area it is estimated that Sumatra, with its 170,744 square miles,[1] is thirteen times the size of Holland, of which country the island is in large measure a dependency. The northern half runs obliquely parallel to the Malay Peninsula, from which it is separated by the Strait of Malacca, and the southern end is separated by the narrow Sunda Strait from Java. Unlike Java, Sumatra has a series of considerable islands (Nias Islands, Mentawei Islands, &c.) arranged like outworks in front of the coast that faces the open Indian Ocean. The general physical features of the island are simple and striking: a range of lofty mountains extends throughout its whole length, their western slopes descending rapidly towards the ocean and their eastern looking out over a vast alluvial tract of unusual uniformity. This mountain range is known as Bukit Barisan or Chain Mountain. It varies in average height from 1500 to 6000 feet, and consists of three or four ridges separated by plateau-like valleys. Among its more remarkable summits are Ya Mura or Gold Mountain, near the north end (6879 feet), Seret Berapi or Merapi (5857 feet), in 0° 44′ N. lat., Pasaman or Mount Ophir (10,866), Merapi (9563), Indrapura, in 1° 36′ S. lat. (11,800), which has the reputation of being the culminating point of the whole island, Dempo (10,000), and Abong Abong (10,000). The summit of Indrapura was reached by the Central Sumatran Expedition of 1877-79. Towards the north end of the island the spurs of the main chain sometimes extend towards the neighbourhood of the east coast. Owing to this configuration of the island, the water-courses of the western side are comparatively short: only very few of them are large enough to be navigable. Those of the eastern slope, on the other hand—such as the Tamiang, the Simpang, the Asahan, the Kubu, the Siak, the Indragiri, the Jambi, the Kampas, the Palembang—are longer, and can not unfrequently carry vessels of considerable burden. In their lower courses they form enormous inosculating deltas. The mountainous regions contain numerous lakes, many of them evidently the craters of extinct volcanoes. When, as sometimes happens, two or three of these craters have merged into one, the lake attains a great size. Amongst the larger lakes may be mentioned the Tao Silalahi, with its offshoots Tao Muara and Tao Balige, Manindji, to the west of Fort de Kock, Sinkarah, south-east of Fort de Kock, Korintji, inland from Indrapura; Ranau, inland from Tampah; and the lake of the X. Kotas, in the Padang Highlands.

Volcanoes.—Sumatra still possesses several centres of volcanic eruption, and in 1883 its southern extremity shared with Java in the disasters of the Krakatoa outbreak. Indrapura sends up from time to time heavy columns of smoke. Merapi,[2] the most active of the volcanoes in the island, was in full eruption in the years 1807, 1822, 1834, 1845, 1863-64, and 1872. Mt Talang in the Padang Highlands, also has three craters, one of which is filled with molten sulphur. Junghuhn registered sixteen Sumatran volcanoes, and others have since been discovered.

Geology.—A large part of the Sumatran highlands consists of very old (probably Silurian or Devonian) slates and clay schists, combined with hornblende talc and other schists, and traversed by veins of quartz. Granite also plays a considerable part, though it does not come so much to the surface. Carboniferous rocks (marls, sandstones, limestones, &c.) are in some places well developed. Between the Carboniferous period and the Tertiary there is a great blank all through the island. Augite-andesite of late Eocene origin has greatly modified the surface of the country, and constitutes, *inter alia*, the main part of the Barisan range.[3] The Tertiary formation is strongly developed in four different divisions. They are usually considered to be Eocene; but this determination rests on badly preserved fossils. The oldest or breccia division consists of débris of carboniferous limestone, syenites, and granites, sometimes in the form of breccia proper, sometimes in that of sandstones or marl clays. The fish remains found in the marls have led some palæontologists to assign a greater antiquity than that of Eocene to these strata, while others, again, consider them to be Miocene. Above this division (apparently absent in south Sumatra) comes the second of sandstones, clay rocks, coal-beds, and coal. The coal appears to be the result of a vegetation which grew *in situ*. Above the coal is sandstone, sometimes 1000 feet thick. The third division consists of marly sandstones of evidently marine origin; it is well developed in west Sumatra, but is absent from the south of the island. The fourth division is a limestone, rich in remains of corals, molluscs, echinids, and especially in *Orbitoides*; it is well developed both in the west and in the south. Miocene deposits are more abundant in the south than in the west. At Lubu Lintang in the Benkulen residency the Eburna fossils are characteristic.[4]

Minerals.—Sumatra possesses various kinds of mineral wealth. Gold occurs in the central regions; gold mines have long been worked in Menangkabau and the interior of Padang, and gold-washing is carried on in several of the streams. Tin, which forms the staple of the neighbouring island of Bangka or BANCA (*q.v.*), is found more especially in Siak and the "division" of the L. Kotas. Copper mines are worked in the Padang Highlands (most largely in the district of Lake Sinkarah) and at Muki in Achin. Iron is not unfrequent, and magnetic iron is obtained at the "Iron Mountain" near Fort van der Capellen (Tanah Datar). Coal seams exist in the Malabuh valley (Achin),[5] in the Sinamu valley, and on both sides of the Ombilin (Umbilin) river; the Ombilin field was brought into notice more especially by Mr D. D. Veth of the 1877-79 expedition. Lignite of good quality is found in several localities. Oil wells are worked at Langkat and other places; and arsenic, saltpetre, alum, naphtha, and sulphur may be collected in the volcanic districts.

Administrative Divisions.—The process by which the Dutch have advanced to their present position in Sumatra has been a very gradual one, and even yet, though their supremacy is effective all round the coast, much of the interior remains practically unpossessed. The following are the more important political subdivisions of the country.

A. The Dutch government of the West Coast (area 46,212 square miles), extending along the shore of the Indian Ocean from Triumon, 2° 53′ N. lat., to the Mandjuta, 2° 25′ S. lat., comprises the residencies Padang, Tapanuli, and the Padang Highlands (*Padangsche Bovenlanden*)

[1] The triangulation of Sumatra was commenced in June 1883 by the measurement of a base line 4857 metres (nearly 3⅓ miles) long in the neighbourhood of Padang.

[2] For an account of changes in the principal crater see Verbeek's paper in *Natuurk. Tijdschr. van Ned. Indie*, 1885.

The governor of the whole government has his residence at Padang. The residency of Padang is bounded south by Benkulen and north by Tapanuli. It contains a large number of separate districts, mostly corresponding to natural divisions formed by mountain-spurs or river valleys. Among the rest are Indrapura, Tapan, Lunang, and Silaut, which form the regency of Indrapura, and are the remains of the ancient kingdom of that name. Administratively Padang is divided into Ayer Bangis and Rau, Priaman, Padang, Painan. The headquarters of Ayer Bangis and Rau is Talu, to the north of Mt Ophir. Ayer Bangis itself is on the coast, and has a good roadstead on one of the islands that protect its bay. At Rau is the Dutch fort of Amerongen, and to the north-west the old fort of Balong or Sevenhoven. Padang is a town of some 2000 houses and 15,000 inhabitants, with a Chinese settlement and a European quarter. It is the chief market in Sumatra for gold. Indrapura lies about 8 miles up the river of its own name, and is now only an unimportant village of bamboo huts. The residency of Tapanuli is divided into Siboga (which includes the Nias Islands), Natal, Mandeling and Angkola, Padang Lawas. The town of Siboga has considerable commercial importance, the bay on which it stands being one of the finest in all Sumatra. Tapanuli, the ancient capital, and Sinkil, a commercial town, also deserve to be mentioned. In Natal (properly Natar) the leading places are Jambur, Sinkuang, and Natar. Padang Sidempuan, the chief town of Mandeling and Angkola, lies to the south of Mt Lubu Raya. Fort Elout was formerly the military centre in Great Mandeling. The residency of the Padang Highlands lies east of Padang proper. The whole surface is mountainous, and the natural districts are very numerous. Agam, Batipu and the X Kotas,[1] the L Kotas, Tanah Datar, and the XIII and IX Kotas form the five administrative divisions. Bukit Tinggi, or, as it is usually called, Fort de Kock, is the capital of the residency; other places of note are Bondjol, Padang Pandjang Payakombo, Fort van der Capellen, Pagar Rujung (the residence of the last prince of Menangkabau), Priyangan (the remains of another capital of Menangkabau), Sinkarah, and Solok. To the government of the West Coast belong the following islands:—Banyak Islands, a small limestone group, well wooded and sparsely peopled; Nias Islands, with an area of 2523 square miles; Batu Islands (Pulu Pingi, Pulu Baar, Tanah Masa, Tanah Balla, &c., area 630 square miles); Mentawei and Pageh or Nassau Islands (area 4200 square miles); Engano (area 360 square miles), annexed by Holland in 1863 and seldom visited. The Nias Islands are a very interesting group (see Dr Schreiber in *Petermann's Mittheil.*, 1881). There are no volcanoes, but earthquakes are very frequent. In the north the villages are mainly perched on steep hills reached by ladders; in the south they are larger and occupy low-lying sites.

B. The residency of Benkulen or Bencoolen (*i.e.*, Bang Kulon, "west coast") lies along the west coast from the Mandjuta to the south end of Sumatra. It is divided into eight districts:—Mokko-Mokko; Lais or Sungei Lama; the district (*ommelanden*) of Benkulen; the capital Benkulen; Seluma; Mana and Pasumah Ulu Mana; Kauer; and lastly Kru. Among the noteworthy places are Mokko-Mokko, with the old English fort Anna; Bantal; Lais (Laye), the former seat of the English resident; and Benkulen, the capital, with 12,000 inhabitants, Fort Marlborough, and a Chinese kampong (see BENCOOLEN).

C. The residency of the Lampong districts, separated from Palembang by the Masudji river, is partly mountainous (Lampong Peak 6800 feet), partly so flat as to be under water in the rainy season. It is divided into the districts of Telok Betong, Tulang Bawang, Seputih, Sekampong, Katimbang, and Semangka. The more important places are Telok Betong, chief town of the residency, Menggala (with a good trade), Gunung Sugi, Sukadana, Tandjong Karang, Beniawang.

D. The residency of Palembang consists of the former kingdom of this name, various districts more or less dependent on that monarchy, and (since 1839) the kingdom of Jambi. With the exclusion of this last it is divided into the administrative districts of Palembang; Tebing Tinggi; Lematang Ulu, Lematang Ilir, and the Pasumah country; Komering Ulu, Ogan Ulu, Inim, and the Ranau districts; Musi Ilir; Ogan Ilir, Komering Ilir, and Blidah; and Ilirau and Banyu Asin. In the kingdom of Jambi the government is left in the hands of the native chief. The town of Palembang is a large place of 50,000 inhabitants (2500 Chinese), with extensive barracks, hospitals, &c., a mosque (1740), considered the finest in the Dutch Indies, and a traditional tomb of Alexander the Great. A good description of the town and its river approaches is given by Mr Forbes.

E. The kingdom of Indragiri (along with Kwanten and the districts of Reteh and Mandah) is administratively subject to the residency of Riouw.

F. The residency of the East Coast was formed in 1873 of the territory of Siak and its dependencies and the state of Kampar. It consists of five divisions,—the island Bengkalis, Siak proper, Labuan Batu, Asahan, Deli. The island has an area of 529 square miles and a population of 5000. Deli is the most important part of the residency,—having been since 1870 the seat of the Amsterdam Deli Company, engaged in growing tobacco, coffee, &c.

G. In 1878 the Achin (Atjeh) kingdom was turned into a Dutch government, but the greater part of the territory is still but little known. Compare ACHIN, vol. i. p. 95 *sq.*

Flora.—Though Sumatra is separated from Java by so narrow a strait, the botanist at once finds that he has broken new ground when he crosses to the northern island, and the farther he advances inward the more striking becomes the originality of the flora. The alang fields, which play a great part in Java, have even a wider range in Sumatra, descending to within 700 or 800 feet of sea-level; wherever a space in the forest is cleared this aggressive grass begins to take possession of the soil, and if once it be fully rooted the woodland has great difficulty in re-establishing itself. Among the orders more strongly represented in Sumatra than in Java are the *Dipterocarpaceæ*, *Chrysobalanaceæ*, sclerocarp *Myrtaceæ*, *Melastomaceæ*, Begonias, *Nepenthes*, *Oxalidaceæ*, *Myristicaceæ*, *Ternstrœmiaceæ*, *Connaraceæ*, *Amyridaceæ*, *Cyrtandraceæ*, *Epacridaceæ*, and *Eriocaulaceæ*. Many of the Sumatran forms which do not occur in Java are found in the Malay Peninsula. In the north the pine tree (*Pinus Merkusii*) has advanced almost to the equator, and in the south are a variety of species characteristic of the Australian region. The distribution of species does not depend on elevation to the same extent as in Java, where the horizontal zones are clearly marked; and there appears to be a tendency of all forms to grow at lower altitudes than in that island. A remarkable feature of the Sumatran flora is the great variety of trees that vie with each other in stature and beauty, and as a timber-producing country the island ranks high even among the richly wooded lands of the archipelago.[2] The process of reckless deforestation is, however, beginning to tell on certain districts,—the natives often destroying a whole tree for a plank or rafter. The principal cultivated plants, apart from sugar-cane and coffee, are rice (in great variety of kinds), the cocoa-nut palm, the areng palm, the areca and the sago palms, maize (jagung), yams, and sweet potatoes; and among the fruit trees are the Indian tamarind, the blimbing, pomegranate, jambosa, guava, papaw, orange, and lemon. Even before the arrival of Europeans Sumatra was known for its pepper plantations, and these still form the most conspicuous feature of the south of the island. For the foreign market coffee is the most important of all the crops,—the Padang districts being the chief seat of its cultivation. The average value of the coffee brought to market in Padang in the three years 1880-82 was £521,000. Benzoin was formerly obtained almost exclusively from Sumatra from the *Styrax Benzoin*.[3]

[1] "Kota" means settlement or township, and a great many of the districts are named from the number of kotas they contain; thus in Agam we have the VII. Kotas, the VIII. Kotas, &c.

[2] The Central Sumatra Expedition alone collected specimens of about 400 kinds of timber.

[3] See Miquel, *Flora Ind. Batavæ*, Suppl. 1, "Prodr. Floræ Sumatranæ," 1860.

Fauna.—Snellemann confirms the statement of Wallace that no trace has been found of the orang-outan (*Simia satyrus*). The siamang (*Hylobates syndactylus*), an ape peculiar to the island, fills the woods with the cry "*uua uua*." The ungko (*Hylobates agilis*) is not so common. A fairly familiar form is the simpei (*Semnopithecus melalophus*). No apes are found on the plateau of Alahan Pandjang and the slopes of the mountains above 1500 metres. The tjigah (*Cercocebus cynomolgus*) is the only ape found in central Sumatra in a tame state. The pig-tail ape (*Macacus nemestrinus*)—as Raffles described it in his "Descriptive Catalogue of a Zoological Collection made in Sumatra," *Trans. Linn. Soc.*, 1820, vol. xiii. p. 243—is employed by the natives of Benkulen to ascend the cocoa-nut trees for the purpose of gathering the nuts. The *Galeopithecus volans* ("kubin," "flying cat," or "flying lemur") is fairly common. Bats of from twenty to twenty-five species have been registered; in central Sumatra they dwell in thousands in the limestone caves. The *Pteropus edulis* ("kalong," "flying fox") is to be met with almost everywhere, especially in the durian trees. The tiger frequently makes his presence felt, but is seldom seen, and less frequently hunted; he prefers to prowl in what the Malays call tiger weather, that is, dark, starless, misty nights. The "clouded tiger" or rimau bulu (*Felis macrocelis*) is also known, as well as the Malay bear and wild dog. *Paradoxurus musanga* ("coffee-rat" of the Europeans) is only too abundant; *Arctictis binturong* appears to be rare. The Sumatran hare (*Lepus netscheri*), discovered in 1880, adds a second species to the *Lepus nigricollis*, the only hare previously known in the East Indian Archipelago. The *Manis javanicus* is the only representative of the *Edentata*. The *Pachydermata* are strongly characteristic of the Sumatran fauna: not only are the rhinoceros (*Rh. sumatranus*), the *Sus vittatus*, and the *Tapirus indicus* common, but the elephant (altogether absent from Java) is represented by a peculiar species. The Sumatran rhinoceros differs from the Javanese in having two horns, like the African variety. Its range does not extend more than 8500 feet above sea-level, and that of the elephant not above 4900 feet. The wild *Bos sundaicus* does not appear to exist in the island. The *Antilope sumatrensis* (kambing utan) has been driven to the loneliest parts of the uplands. *Cervus equinus* is widely distributed, *Cervus muntjac* less so.[1]

Inhabitants.—The bulk of the Sumatran population is Malayan; but to what extent the Malay has absorbed pre-Malayan blood is still open to investigation. The Kubus, a race or tribe still found in an emphatically savage state in the interior, have been by some regarded as the remains of an aboriginal stock; but Mr J. G. Garson, reporting on Kubu skulls and skeletons submitted to him by Mr Forbes, comes to the conclusion that they are decidedly Malay, though the frizzle in the hair might indicate a certain mixture of Negrito blood (*Journ. Anthrop. Inst.*, 1884). They speak the Malay dialect of the district to which they belong.

One of the most interesting of all the savage or semi-savage peoples is the Battaks or Batahs. About these a great deal has been written since Junghuhn published his *Die Battaländer* in 1847. It is not known whether they were settled in Sumatra before the Hindu period. Their language contains words of Sanskrit origin and others most readily referred to Javanese, Malay, Menangkaban, Macassar, Sundanese, Niasese, and Tagal influence. At the present time they occupy the country to the south-east of Achin, in the centre of which lies the great Toba Lake; but it is evident that they formerly possessed, or at least were present in, various other districts both north and south. The process of absorption into the Achin and Malay population which is now rapidly going on seems to have been long at work. In many points the Battaks are quite different from the Malay type. The average stature of the men is about 5 feet 4 inches, of the women 4 feet 8 inches. In general build they are rather thickset, with broad shoulders and fairly muscular limbs. The colour of the skin ranges from dark brown to a yellowish tint, the darkness apparently quite independent of climatic influences or distinction of race. The skull is rather oval than round. In marked contrast to the Malay type are the large black long-shaped eyes, beneath heavy black or dark brown eyebrows. The cheek-bones are somewhat prominent, but less so than among the Malays. J. B. Neumann[2] reckons the inhabitants of the whole river basin of which he treats at 50,000. The Battak language,[3] especially the Toba dialect, has been studied by Van der Tuuk (*Bataksch Woordenboek*). On the borders of Palembang and Benkulen live the Redjangers, a peculiar tribe who still employ a distinctive written character, which they cut with a kris on bamboo or lontar. The same character is employed by the Pasumahs, who bear traces of Javanese elements or influence. Full details as to the various forms are given by Van Hasselt, *Volksbeschr. en Taal van Mid.-Sumatra* (1877-79 expedition). The original stock of the Achinese appears, according to K. H. F. van Langen (*Tijdschr. voor Ind. Taal-, Land-, en Volken-Kunde*, Batavia, xxviii.), to have consisted of the Mantris, who seem to have been driven inland by the Battaks and the Cheties (Tjeties) or Hindus. The Achinese language is at present spoken in four main dialects, of which the purest or most cultured is that of the XXV. and XXVI. Mukims. It shows, besides the Mantri element, Malay, Battak, Hindu, and Arabic influence. The inhabitants of the Nias Islands have a special tongue, which has been studied by Herr Sundermann.

The physical conditions of large tracts render it certain that as a whole the island cannot be thickly peopled. In 1881 the Government *Almanac* gave the population of the Dutch possessions as 2,142,873 (2894 Europeans, 2,098,984 natives, 11,289 Chinese, 1929 "Arabs," and 27,777 Orientals of other stock). To this considerable additions must be made, as the kingdom of Achin (356,000 at least), as well as Indragiri and Kwanten (about 30,000). Perhaps a fair estimate for the whole is somewhat under 3,500,000. The Nias Islands would add 230,000 to the total. The most populous region is the government of the West Coast.

History.—As far as is known, Sumatran civilization and culture are of Hindu origin, and it is not improbable that the island was the first of all the archipelago to receive the Indian immigrants who played so important a part in the history of the region. Certain inscriptions discovered in the Padang Highlands seem to certify the existence in the 7th century of a powerful Hindu kingdom in Tanah Datar, not far from the site of the later capital of Menangkabau. In these inscriptions Sumatra is called the "first Java." The traces of Hindu influence still to be found in the island are extremely numerous, though far from being so important as those of Java. There are ruins of Hindu temples at Butar in Deli, near Pertibi, on the Panbi river at Jambi, in the interior of Palembang above Lahat, and in numerous other localities. One of the principal Hindu ruins is at Muara Takus on the Kampar river.[4] The buildings (including a stupa 40 feet high) may possibly date from the 11th century. At Pagar Rujung are several stones with inscriptions in Sanskrit and Menangkabau Malay. Sanskrit words occur in the various languages spoken in the island; and the *Ficus religiosa*, the sacred tree of the Hindu, is also the sacred tree of the Battaks. At a later period the Hindu influence in Sumatra was strengthened by an influx of Hindus from Java, who settled in Palembang, Jambi, and Indragiri, but their attachment to Sivaism prevented them from coalescing with their Buddhist brethren in the north. In the 13th century Mohammedanism began to make itself felt, and in course of time took a firm hold upon some of the most important states. In Menangkabau, for instance, the Arabic alphabet displaced the Kawi (ancient Javanese) character previously employed. Native chronicles derive the Menangkabau princes from Alexander the Great; and the Achinese dynasty boasts its origin from a missionary of Islam. The town of Samudera was at that period the seat of an important principality in the north of the island, whose current name is probably a corruption of this word.[5] Mr Wenniker in 1881 found a village called Samudra near Pasei (Pasir), which possibly indicates the site.

Subjoined are a few leading events in the recent history of Sumatra. The island, or rather the portions possessed by the Dutch, were British from 1811 to 1816. 1821. Second expedition against Palembang; Palembang captured 23d June. 1822. Menangkabau recognized Dutch authority. 1825. Benkulen taken over from the English in May. 1837. Cultivation of coffee extended in West Coast region by Governor A. v. Michiels. 1840. Extension of the West Coast government to Singkil. 1851. Revolt suppressed in Palembang; expedition to the Lampong districts. 1853. Cholera rages in the island; Raja Tiang Alam, ringleader of the revolt in Palembang, surrenders. 1858. Expedition against Jambi; sultan dethroned and treaty made with his successor. 1860. Redjang added to Palembang residency. 1863. Expedition against Nias. 1865. Expedition against Asahan and Serdang (East Coast). 1872. Agreement with the British Government in regard to Sumatra. 1873. War in Achin commenced. 1874. Capture of the kraton of Achin. 1876. Capture of the VI., IV., and IX. Mukims (Achin); expedition against Kota Jutan (East Coast); emancipation of slaves on West Coast. 1878. Benkulen made a residency; civil administration of Achin and dependencies entrusted to a governor.

The literature dealing with Sumatra is very extensive. Of the older works the best known is Marsden's *History of Sumatra*, 1811. A full list of other authorities will be found in Veth's *Aardrijkskundig Woordenboek van Nederl. Indie*, 1869. Among recent works by far the most important is *Midden Sumatra, Reizen en Onderzoekingen der Sumatra Expeditie, 1877-1879* (1882), edited by Prof. P. J. Veth. See also Brau de Saint Pol Lias, *Île de Sumatra*, 1884; Bastian, *Indonesien*; Buijs, *Twee Jaren op Sumatra's Westkust*; M. Fauque, "Rapport sur un Voyage à Sumatra," in *Archives des Missions Scient.*, 3d ser. vol. xii.; Kielstra, *Beschrijving van der Atjeh Oorlog*, 1885-86; and "Sumatras West Kust van 1819-1825," in *Bijd. tot Land-, &c., -Kunde*, 1887. (H. A. W.)

[1] For the birds see Forbes's *Naturalist's Wanderings*. On this, as on other branches of natural history, elaborate treatises appear in *Midden Sumatra*.

[2] "Het Pane en Bila Stroomgebied," in *Tijdsch. Ned. Aardrijksk. Gen.*, 1886.

[3] Mr C. A. van Ophuijsen has published (in *Bijd. tot Land-, Taal-, en Volken-Kunde*, 1886) an interesting collection of Battak poetry. He describes a curious leaf language used by Battak lovers, in which the name of some leaf or plant is substituted for the word with which it has greatest phonetic similarity.

[4] See descriptions of it in *Tijdschr. van Ind. Taal-, Land-, en Volken-Kunde*, 1860 and 1879, and *Verhandel. Batav. Gen. van Kunst en Wetensch.*, 1881.

[5] All the facts relating to this derivation are given in Yule and Burnell, *Glossary of Anglo-Indian Words*, s.v. "Sumatra."

SUMBAL, or SUMBUL, also called MUSK ROOT, a drug recently introduced into European medical practice It consists of the root of *Ferula Sumbul*, Hook, a tall Umbelliferous plant found in the north of Bokhara, its range apparently extending beyond the Amur It was first brought to Russia in 1835 as a substitute for musk, it was subsequently recommended as a remedy for cholera, and in 1867 was introduced into the British pharmacopœia The root as found in commerce consists of transverse sections an inch or more in thickness and from 1 to 3 or more inches in diameter It has a dark thin papery bark, a spongy texture, and the cut surface is marbled with white and blackish or pale brown, it has a musky odour and a bitter aromatic taste Sumbal is used in medicine as an antispasmodic and stimulating tonic, especially in nervous diseases It owes its medicinal properties to a balsamic resin and an essential oil Of the former it contains about 9 per cent and of the latter one-third per cent The resin is soluble in ether and has a musky smell, which is not fully developed until after contact with water, by dry distillation it yields umbelliferone, $C_9H_6O_3$, a crystalline substance soluble in water, ether, and chloroform, and producing in an alkaline solution a brilliant blue fluorescence, which is destroyed by the addition of an acid in excess

Under the name of East Indian sumbal, the root of *Dorema ammoniacum*, Don, has occasionally been offered in English commerce It is of a browner hue, has the taste of ammoniacum, and gives a much darker tincture than the genuine drug, it is thus easily detected The name "sumbal" (a word of Arabic origin, signifying a spike or ear) is applied to several fragrant roots in the East, the principal being *Nardostachys Jatamansi*, D C (see SPIKENARD) West African sumbal is the root of a species of *Cyperus*

SUMBAWA (properly SAMBAWA or SAMAWA), an island of the East Indian Archipelago, one of the Sunda group, lies between 8° 6′ and 9° 3′ S lat and 116° 47′ and 119° 12′ E long, to the east of Lombok, from which it is separated by the narrow Allas strait Its area is estimated at 5186 square miles The population was computed to number about 150,000 in 1887 The deep Bay of Salee or Sumbawa on the north divides the island into two peninsulas, and the isthmus is further reduced by the narrower Bay of Tjempi (Chempi) entering from the south The eastern peninsula is deeply indented by the Bay of Bima The whole surface of Sumbawa is mountainous G Nyenges, in the western peninsula, is 5560 feet high, and G Tambora, in the eastern, which is said to have lost a third of its elevation in the eruption of 1815, is still 8697 feet high There are no navigable streams The climate and productions are not unlike those of Java, though the rains are heavier, the drought more severe, and the fertility less Sulphur, arsenic, asphalt, and petroleum are the mineral products Mohammedanism prevails throughout the island, except among certain mountain tribes

Sumbawa is divided into four independent states,—Sumbawa proper, Dompo, Sangar, and Bima Two other states on the northern extremity of the island were so devastated by the Tambora eruption of 1815 that their territory, after lying for long uninhabited, was in 1866 divided between Dompo and Sangar Sumbawa proper occupies the western peninsula The residence of the sultan is Sumbawa, 2 miles from the coast of the great bay, in 8° 32′ S lat and 117° 20′ 33″ E long It is surrounded with palisade and ditches The inhabitants of this state employ sometimes the Malay and sometimes the Macassar character in writing A considerable trade is carried on in the export of horses, buffaloes, goats, dinding (dried flesh), skins, birds' nests, wax, rice, katjang, sappanwood, &c Sumbawa entered into treaty relations with the Dutch East India Company in 1674 Dompo is the western half of the eastern peninsula The capital of the state, Dompo, lies in the heart of the country, on a stream that falls into Tjempi Bay Bada, the sultan's residence, is farther west Sangar occupies the north-western promontory of the island, and Bima the extreme east Bima or Bodjo, the chief town of the latter state, lies on the east side of the Bay of Bima, it has a stone-walled palace and a mosque, as well as a Dutch fort The population of Bima is curiously divided into twelve guilds or castes (*dari*) In the town is a Government Christian school dating from 1874

SUMMARY JURISDICTION By a court of summary jurisdiction is meant a court in which cases are heard and determined by a justice or justices of the peace, without the intervention of a jury Such a court has duties to perform of two different kinds It either hears and determines a case in a judicial capacity, or it acts rather in a ministerial capacity where a *prima facie* case has been established, as by issuing a warrant of distress for non-payment of poor rate, or by committing an accused person for the decision of a higher court, generally assizes or quarter sessions It is to the court acting in the former capacity that the term "court of summary jurisdiction" more strictly applies Ever since the first institution of justices of the peace (see JUSTICE OF THE PEACE), the tendency of English legislation has been to enlarge their jurisdiction and to enable offences of a less heinous nature to be tried in their courts without a jury This inroad upon the functions of the jury can only be made by legislation "The common law is a stranger to it, unless in the case of contempts," says Blackstone At common law all offences must be proceeded against by indictment, and an indictment can only be tried before a jury Even where an offence is created by statute and is unknown to the common law the procedure must be by indictment, unless the statute creating the offence or some other statute specially makes it summary The history of the gradual growth of summary jurisdiction will be found in Stephen, *History of the Criminal Law*, vol i chap iv The summary jurisdiction exercised by justices is the only one of much practical importance It is unnecessary to do more than mention in passing the two other kinds named by Blackstone, that of the commissioners of taxes for revenue offences and that of the superior courts for CONTEMPT OF COURT (*q v*) A very remarkable case of the latter is the power given to a judge by 12 Geo I c 29, s 4, to summarily sentence to seven years' penal servitude a solicitor practising after conviction for perjury, forgery, or barratry

The principal Acts now dealing with summary jurisdiction are the Summary Jurisdiction Act, 1848[1] (11 and 12 Vict c 43), one of what are called Jervis's Acts, and the Summary Jurisdiction Act, 1879 (42 and 43 Vict c 49) The former consolidated the law up to that time of a large number of Acts, but only to a certain extent, for a considerable number of previous enactments dealing in a greater or less degree with this subject are still law, the earliest being 5 Hen IV c 10 It also amended the law in several important particulars The amendment was in the direction of greater simplicity of procedure, and related to both criminal and only quasi criminal matters The procedure under the Act is shortly this In all cases where an information is laid or complaint made the justices are, on proof of a *prima facie* case, to issue a SUMMONS (*q v*) An information is laid in criminal matters in which the decision of the justices, if adverse to the defendant, would be a conviction A complaint is made where the decision of the justices in such an event would be an order for the payment of money or otherwise in what may be called only quasi-criminal matters, *e g*, claims under the Employers and Workmen Act If the summons is disobeyed, a warrant may (in criminal charges only) issue in the first instance at the discretion of a justice The warrant is good only within the local jurisdiction of the justice issuing it, and, if it is required to be executed in another jurisdiction, it must be backed, *i e*, endorsed, by a justice of that jurisdiction (unless in case of a fresh pursuit, when it is good for 7 miles beyond the bounds of the jurisdiction in which it was issued) Complaints need not be in writing, informations usually are, though the Act does not make writing necessary Where a warrant issues in the first instance, the information must be upon oath In all cases not otherwise provided for, the information must be laid or complaint made within six calendar months from the time at which the matter of the information or complaint arose The hearing is in open court, and parties may appear by counsel or solicitor If both parties appear, the justices must hear and determine the case If the defendant does not appear, the justices may hear and

[1] This name of the Act of 1848 is an example of a title of an Act conferred retrospectively (see STATUTE) The name was given to it by the Act of 1879 In the same way the name of the Scotch Summary Procedure Act, 1864, was changed to that of the Summary Jurisdiction Act, 1864, by the Summary Jurisdiction Act, 1881

determine in his absence, or may issue a warrant and adjourn the hearing until his apprehension. If the complainant does not appear, the justices may dismiss the complaint or adjourn the hearing. The punishment inflicted may be fine or imprisonment, or both. Imprisonment as a rule cannot exceed six months. The regular mode of proceeding where a conviction adjudges a pecuniary penalty, or an order requires payment of a sum of money, is by issue of a warrant of distress to be levied on the goods of the defendant. The court usually consists of two or more justices, but the lord mayor or an alderman of the City of London, a metropolitan police magistrate, and a stipendiary magistrate have each the authority of two justices. The Act further makes provision for curing defects in form in the proceedings for the payment of costs, for removing difficulties as to the boundaries of jurisdiction, and for various other matters. The schedule gives forms of proceedings, which are as far as possible to be followed. The Act of 1879 amended the Act of 1848 in several important particulars, chiefly in the direction of greater leniency and enlarged jurisdiction and power of appeal. A greater discretion in the infliction of punishment is conferred on the court. A scale of imprisonment in respect of non payment of a fine or default of distress is fixed at periods varying according to the amount of the fine unpaid, but in no case exceeding three months (except in certain revenue offences, where the limit is six months), and without hard labour, unless hard labour is specially authorized by the Act on which the conviction is founded. Time may be given for payment of money, or it may be ordered to be paid by instalments, or security may be taken. Summary trial of children under twelve is allowed at the discretion of the court in case of any indictable offence other than homicide, unless objection is made by the parent or guardian. A child cannot on summary conviction be imprisoned for more than a month or fined more than 40s. Summary trial of juvenile offenders between twelve and sixteen and of adults is allowed in certain crimes mentioned in the Act, if the accused assents and foregoes his right to trial by jury. There are cases in which the court can deal summarily with an adult pleading guilty where it would have been necessary to commit him for trial had he pleaded not guilty. The court may in trivial cases discharge the accused without punishment or with only a nominal punishment. Improvements are made in the practice as to sureties, recognizances (see SURETY, RECOGNIZANCE), and the issue and execution of warrants of commitment and distress. The issue of such a warrant may be postponed if the court thinks fit. The wearing apparel and bedding of a person and his family, and the tools and implements of his trade to the value of £5, are exempt from distress. Imprisonment may in certain cases be ordered instead of distress. The right of appeal is much extended. An appeal now lies from every conviction or order adjudging imprisonment without the option of a fine where the accused did not plead guilty. The appeal by the Act of 1884 must be in accordance with the procedure of the Act of 1879, or of any subsequent Act giving a right of appeal in the particular case. The appeal is to QUARTER SESSIONS (*q.v.*). A summons or warrant is not avoided by the death or cesser of office of the justice issuing it. Under the powers of the Act rules and forms were framed which came into effect on 1st January 1880. The Summary Jurisdiction (Process) Act, 1881 (44 and 45 Vict. c. 24, applying to Great Britain, but not to Ireland), gave additional facilities for serving and executing the process of an English court of summary jurisdiction in Scotland or of a Scotch court in England, on endorsement in the country where it is executed. The Summary Jurisdiction Act, 1884 (47 and 48 Vict. c. 43), repealed a number of enactments rendered obsolete by the Acts of 1848 and 1879 and explained certain sections of those Acts as to which doubts had arisen. There are numerous other enactments dealing less directly with the powers of courts of summary jurisdiction. For instance, the Merchant Shipping Acts give justices large powers in case of salvage claims and of offences by seamen. The Criminal Law Consolidation Acts of 1861 give them limited jurisdiction in larceny, coining, malicious injuries to property, and offences against the person. Among many other Acts conferring summary jurisdiction are the Army, Bastardy, Customs, Employers and Workmen, Game, Highway, Licensing, Post Office, and Vagrant Acts. Some of the later Acts, such as the Customs and Army Acts, apply to the United Kingdom. The decision of a court of summary jurisdiction may be reviewed by, besides appeal, a writ of certiorari, mandamus, or habeas corpus, or by statement of a special case.

Scotland.—Summary jurisdiction in Scotland depends chiefly upon the Summary Jurisdiction Acts, 1864 and 1881. A court of summary jurisdiction includes the sheriff court. The Acts follow, *mutatis mutandis*, the lines of English legislation. All proceedings for summary conviction or for recovery of a penalty must be by way of complaint according to one of the forms in the schedule to the Act of 1864. The English summons and warrant are represented in Scotland by the warrant of citation and the warrant of apprehension. Where no punishment is fixed for a statutory offence, the court cannot sentence to more than a fine of £5 or sixty days' imprisonment, in addition to ordering caution to keep the peace. The Act of 1881 adopts many of the provisions of the English Act of 1879. In addition, it confers the discretion as to punishment to a sheriff trying by jury in cases where the prosecution might have been by complaint under the Acts. Appeals from courts of summary jurisdiction are now mainly regulated by 38 and 39 Vict. c. 62, and proceed on case stated by the inferior judge.

Ireland.—The principal Acts dealing with the subject are the Summary Jurisdiction and Petty Sessions Acts, 1851 (14 and 15 Vict. cc. 92, 93). These Acts are more extensive in their purview than the English Acts, as they form in a great degree a code of substantive law as well as of procedure. The exceptional political circumstances of Ireland have led to the appointment of resident magistrates under 6 and 7 Will. IV. c. 13, and to the conferring at different times on courts of summary jurisdiction of an authority, generally temporary, greater than that which they can exercise in Great Britain. Recent instances are the Peace Preservation Act, 1881, and the Prevention of Crime Act, 1882. The provisions of the English Act of 1879 as to children were extended to Ireland by 47 and 48 Vict. c. 19.

United States.—By Art. III. s. 2 of the constitution the trial of all crimes, except in cases of impeachment, is to be by jury. By Art. V. of the amendments no person can be held to answer for a capital or otherwise infamous crime unless on a presentment or indictment of a grand jury. Considerable changes have been made by State legislation in the direction of enlarging the powers of courts of summary jurisdiction. (J. W†.)

SUMMONS (*summonitio*) is a legal form demanding the attendance of a person in parliament (see PEERAGE, vol. xviii. p. 462) or before a court of justice. The term as it applies to courts of justice is used both in civil and in criminal procedure, but is not applied universally to all cases of demanding attendance. Thus in the Probate, Divorce, and Admiralty Division the summons is usually, following the civil law, called a "citation," while a summons to a witness (at least in the superior courts) bears the name of "subpœna," taken from the initial words of the penal clause in its Latin form. Whatever be the name, the principle of law is invariable, that a court before proceeding to adjudicate should bring before itself by some formal legal process all persons interested in the decision or able to influence the decision by giving evidence as material witnesses. The oral summons, like the oral pleading, seems to have been earlier in time than the written form. In Roman law the oral *in jus vocatio* existed centuries before the written *libellus conventionis*. The antiquity and importance of the summons as a legal form in England is shown by the presence of the "sompnour," or summoner of the ecclesiastical court, as one of the characters in the *Canterbury Tales*, and by the comparative frequency of "Sumner" as a surname. In civil procedure a summons may be issued either in the High Court or in an inferior court, such as a county court. In the High Court all actions are commenced by writ of summons. In the High Court the summons (in this case not in the form of a writ) is also a convenient mode of determining interlocutory matters by a judge or some other officer of the court—such as a master in the Queen's Bench Division or a chief clerk in the Chancery Division—without the necessity of bringing the case into court.

The tendency of recent legislation is towards the increased use of the summons as a mode of presenting a case for decision. For instance, under the Vendor and Purchaser Act 1874, and the Conveyancing Act, 1881, many important questions, even of title to real property, may be raised on summons. It thus approaches very nearly to PLEADING (*q.v.*), in fact, the definition of pleading in the Judicature Act, 1873, s. 100, includes summons. The Rules of the Supreme Court, 1883, introduced two new forms of summons,—(1) the general summons for directions, by which several matters may be included in a single summons which before the rules must have been the subject of separate applications, (2) the originating summons in the Chancery Division, by which proceedings may be commenced without writ for certain kinds of relief specified in the rules (see Ord. lv. r. 3). The originating summons to a great extent supersedes the action for administration of a trust or of the estate of a deceased person.[1] An ordinary summons must be served

[1] A similar practice existed before 1883 under the powers given by 15 and 16 Vict. c. 86, but was very limited in its operation, as it applied simply to the personal estate of a deceased person.

two, an originating summons seven, clear days before its return A decision on a summons is generally subject to appeal In the Chancery Division it is customary to adjourn into court the consideration of a summons of more than ordinary importance The appendix to the Rules of 1883 contains forms of every kind of summons in the High Court In the county courts an action is commenced by plaint and summons Two kinds of summons are in use,—the ordinary and the default summons The latter is an optional remedy of the plaintiff in actions for debts or liquidated demands exceeding £5, and in all actions for the price or hire of goods sold or let to the defendant to be used in the way of his calling It may also issue by leave of the judge or registrar in other cases, with the single exception that no leave can be given in claims under £5 where the claim is not for the price or hire of goods sold or let as above, if the affidavit of debt discloses that the defendant is a servant or person engaged in manual labour The advantage of a default summons is that judgment is entered for the plaintiff without hearing unless the defendant gives notice of defence within a limited time A default summons must as a rule be served personally on the defendant, an ordinary summons need not be served personally, but may in most cases be delivered to a person at the defendant's house or place of business A summons is also issued to a witness in the county court Forms of summons are given in the County Court Rules, 1886 These include certain special forms used in Admiralty and interpleader actions and in proceedings under the Charitable Trusts Acts, the Friendly Societies Act, 1875, and the Married Women's Property Act, 1882 In criminal law a summons is the mode of securing the attendance of the defendant before a court of summary jurisdiction, whether it be sought to obtain a conviction or an order against him Forms of summons to a defendant, a witness, or a surety will be found in the schedule to the Summary Jurisdiction Act, 1848, and in the rules issued in accordance with the Summary Jurisdiction Act, 1879 (see the article SUMMARY JURISDICTION, *supra*) Forgery of a summons or use of any document falsely purporting to be a summons or professing to act under such a document is punishable as felony under the County Courts Act, 1846, and the Forgery Act of 1861

Scotland —Summons is a term confined in strictness to the commencement of an action in the Court of Session Formerly it was the mode of commencing an action in the sheriff court, but such an action is now commenced by PETITION (*q v*) In some Acts of Parliament, however—*e g*, the Citation Amendment Acts—the term "summons" is certainly used to denote part of the process of an inferior court The summons is a writ in the sovereign's name, signed by a writer to the signet, citing the defender to appear and answer the claim The will of the summons calls upon the defender to appear on the proper *induciæ* A privileged summons is one where the *induciæ* are shortened to six days against defenders within Scotland (6 Geo IV c 120, s 53) Defects in the summons are cured by amendment or by a supplementary summons The summons goes more into detail than the English writ of summons, though it no longer states, as it once did, the grounds of action, now stated in the condescendence and pursuer's pleas in law annexed to the summons The form of the summons is regulated by 13 and 14 Vict c 36, s 1, and Schedule A After the action has been set on foot by summons, the attendance of the parties and witnesses is obtained by citation The Citation Amendment Acts, 1871 and 1882, give additional facilities for the execution of citations in civil cases by means of registered letters In cases in a court of summary jurisdiction the English summons is represented by the warrant of citation

SUMNER, CHARLES (1811-1874), American statesman, was born at Boston, Mass, on 6th January 1811 He graduated at Harvard in 1830, and studied law with Judge Story His natural powers of mind were great, his habits of study intense, and his success immediate and conspicuous Everything seems to have been expected of him, and he disappointed nobody In 1834 he had been admitted to the bar, was editor of the *American Jurist*, and was reporting the decisions of Judge Story For the next three years he was a lecturer in the Harvard law school He then spent three years in Europe, always, however, studying with an intensity that never relaxed Returning, he began the practice of law, but gradually drifted into politics during the anti-slavery struggle In 1851 the few "free-soilers" in the Massachusetts legislature offered to vote for Democrats for other officers in return for Democratic votes for Sumner as United States senator Sumner was thus sent to the Senate, to which he was regularly re-elected for the rest of his life He at once became a man of mark, though not of popularity, in the Senate His fine personal presence, his somewhat florid rhetoric, his wealth of citation from learned and foreign tongues, his wide foreign acquaintance, high culture, and social standing, seem to have staggered his Southern colleagues They could not look down upon him, and they hardly knew what else to do A long series of speeches brought about an assault upon him, 22d May 1856, by Preston S Brooks, a representative from South Carolina, in retaliation for Sumner's criticism of Brooks's uncle, a senator from his State Brooks found Sumner writing in the Senate chamber, and beat him so cruelly that he narrowly escaped death He was absent from his place until 1859, and never fully recovered from the effects of the assault When his party took control of the Senate in 1861 Sumner became one of its foremost members Like Stevens (see STEVENS), he propounded a theory of the relations of the seceding States to the Union which never was endorsed, but had its influence on the outcome of reconstruction In the American Union States are autonomous, but Territories are theoretically under the absolute government of Congress, though in practice Congress gives them as much self-government as is possible or prudent A Territory becomes a State by admission through an Act of Congress Sumner held that the national boundaries of the Union were so fixed that no State could escape from them by secession, that a State's secession was merely an abandonment of its Statehood, so that it fell back into the condition of a Territory and came under the absolute government of Congress This "State-suicide" theory was in due time condemned by the Supreme Court, which held that a State could not lose its Statehood, but Congress had really acted upon it already in several points of reconstruction Sumner's peculiar field was in the Senate committee on foreign relations, of which he was chairman from 1861 until 1871 It was during this period, in 1869, that he urged the "indirect" items of the Alabama claims, sacrificing without hesitation the English popularity which had always been dear to him Within a year or two he felt compelled to oppose the new administration of President Grant in several particulars In the expectation of gratifying the president, the Republican senators removed Sumner from his chairmanship, and, like Seward, he passed his later years in general opposition to the party which he had helped to organize In December 1872 he introduced a resolution that the names of victories over fellow-citizens should be removed from the regimental flags of the army For this his State legislature censured him, but the censure was rescinded just before his death He had been from the beginning of the Civil War the advocate of emancipation and of the grant of full status to the Negroes, and for the last few years of his life his energies were devoted to forwarding his Civil Rights Bill, intended to give the freedmen the same legal rights as the whites He died at Washington on 11th March 1874

Sumner's speeches were collected in 1850 under the title of *Orations and Speeches*, to which was added, in 1856, *Recent Speeches and Addresses* His *Works*, in twelve volumes, were issued in 1875 See also Lester's *Life of Sumner*, 1874, Haskha's *Life of Sumner*, and Pierce's *Memorial and Letters of Sumner*

SUMPTUARY LAWS are those intended to limit or regulate the private expenditure of the citizens of a community They may be dictated by political, or economic, or moral considerations They have existed both in ancient and in modern states In Greece, it was amongst the Dorian races, whose temper was austere and rigid, that they most prevailed All the inhabitants of Laconia were forbidden to attend drinking entertainments, nor could a Lacedæmonian possess a house or furniture which was the work of more elaborate implements than the axe and saw Amongst the Spartans proper, simple and frugal habits of

life were secured rather by the institution of the *pheiditia* (public meals) than by special enactments The possession of gold or silver was interdicted to the citizens of Sparta, and the use of iron money alone was permitted by the Lycurgean legislation "Even in the cities which had early departed from the Doric customs," says K O Muller, "there were frequent and strict prohibitions against expensiveness of female attire, prostitutes alone being wisely excepted" In the Locrian code of Zaleucus citizens were forbidden to drink undiluted wine The Solonian sumptuary enactments were directed principally against the extravagance of female apparel and dowries of excessive amount, costly banquets also were forbidden, and expensive funeral solemnities The Pythagoreans in Magna Græcia not only protested against the luxury of their time but encouraged legislation with a view to restraining it

At Rome the system of sumptuary edicts and enactments was largely developed, whilst the objects of such legislation were concurrently sought to be attained through the exercise of the censorial power The code of the Twelve Tables contained provisions limiting the expenditure on funerals The most important sumptuary laws of the Roman commonwealth were those which follow (1) The Oppian law, 215 B C, provided that no woman should possess more than half an ounce of gold, or wear a dress of different colours, or ride in a carriage in the city or within a mile of it except on occasions of public religious ceremonies This law, which had been partly dictated by the financial necessities of the conflict with Hannibal, was repealed twenty years later, against the advice of Cato Livy (xxxiv 1-8) gives an interesting account of the commotion excited by the proposal of the repeal, and of the exertions of the Roman women against the law, which almost amounted to a female *émeute* (2) The Orchian law, 187 B C, limited the number of guests at entertainments An attempt being made to repeal this law, Cato offered strong opposition and delivered a speech on the subject, of which some fragments have been preserved (3) The Fannian law, 161 B C, limited the sums to be spent on entertainments, it provided amongst other things that no fowl should be served but a single hen, and that not fattened (4) The Didian law, 143 B C, extended to the whole of Italy the provisions of the Fannian law, and made the guests as well as the givers of entertainments at which the law was violated liable to the penalties After a considerable interval, Sulla anew directed legislation against the luxury of the table and also limited the cost of funerals and of sepulchral monuments We are told that he violated his own law as to funerals when burying his wife Metella, and also his law on entertainments when seeking to forget his grief for her loss in extravagant drinking and feasting (Plut, *Sull*, 35) Julius Cæsar, in the capacity of *præfectus moribus*, after the African war re-enacted some of the sumptuary laws which had fallen into neglect, Cicero implies (*Ep ad Att*, xiii 7) that in Cæsar's absence his legislation of this kind was not attended to Suetonius tells us that Cæsar had officers stationed in the market-places to seize such provisions as were forbidden by law, and sent lictors and soldiers to feasts to remove all illegal eatables (*Jul*, 43) Augustus fixed anew the expense to be incurred in entertainments on ordinary and festal days Tiberius also sought to check inordinate expense on banquets, and a decree of the senate was passed in his reign forbidding the use of gold vases except in sacred rites, and prohibiting the wearing of silk garments by men But it appears from Tacitus (*Ann*, iii 5, where a speech is put into his mouth very much in the spirit of Horace's "Quid leges sine moribus Vanæ proficiunt?"), that he looked more to the improvement of manners than to direct legislative action for the restriction of luxury Suetonius mentions some regulations made by Nero, and we hear of further legislation of this kind by Hadrian and later emperors In the time of Tertullian the sumptuary laws appear to have been things of the past (*Apol*, c vi)

In modern times the first important sumptuary legislation was—in Italy that of Frederick II, in Aragon that of James I, in 1234, in France that of Philip IV, in England that of Edward II and Edward III In 1294 Philip IV made provisions as to the dress and the table expenditure of the several orders of men in his kingdom, the most remarkable of which may be seen in Guizot's *Civilisation en France*, leç 15 Charles V of France forbade the use of long-pointed shoes, a fashion against which popes and councils had protested in vain Under later kings the use of gold and silver embroidery, silk stuffs, and fine linen wares was restricted,—at first moral and afterwards economic motives being put forward, the latter especially from the rise of the mercantile theory In England we hear much from the writers of the 14th century of the extravagance of dress at that period They remark both on the great splendour and expensiveness of the apparel of the higher orders and on the fantastic and deforming fashions adopted by persons of all ranks The parliament held at Westminster in 1363 made laws (37 Edw III c 8-14) to restrain this undue expenditure and to regulate the dress of the several classes of the people These statutes were repealed in the following year, but similar ones were passed again in the same reign They seem, however, to have had little effect, for in the reign of Richard II the same excesses prevailed, apparently in a still greater degree Another statute was passed in the year 1463 (3 Edw IV c 5) for the regulation of the dress of persons of all ranks In this it was stated that "the commons of the realm, as well men as women, wear excessive and inordinate apparel to the great displeasure of God, the enriching of strange realms, and the destruction of this realm" An Act of 1444 had previously regulated the clothing, when it formed a part of the wages, of servants employed in husbandry, a bailiff or overseer was to have an allowance of 5s a year for his clothing, a hind or principal servant 4s, and an ordinary servant 3s 4d,—sums equivalent respectively to 50s, 40s, and 33s 4d of our money (Henry) Already in the reign of Edward II a proclamation had been issued against the "outrageous and excessive multitude of meats and dishes which the great men of the kingdom had used, and still used, in their castles," as well as "persons of inferior rank imitating their example, beyond what their stations required and their circumstances could afford", and the rule was laid down that the great men should have but two courses of flesh meat served up to their tables, and on fish days two courses of fish, each course consisting of but two kinds In 1363, at the same time when costumes were regulated, it was enacted that the servants of gentlemen, merchants, and artificers should have only one meal of flesh or fish in the day, and that their other food should consist of milk, butter, and cheese Similar Acts to those above mentioned were passed in Scotland also In 1433 (temp James I), by an Act of a parliament which sat at Perth, the manner of living of all orders in Scotland was prescribed, and in particular the use of pies and baked meats, which had been only lately introduced into the country, was forbidden to all under the rank of baron In 1457 (temp James II) an Act was passed against "sumptuous clething" A Scottish sumptuary law of 1621 was the last of the kind in Great Britain

Ferguson and others have pointed out that "luxury" is a term of relative import and that all luxuries do not deserve to be discouraged Roscher has called attention to the fact that the nature of the prevalent luxury changes with the stage of social develop-

ment. He endeavours to show that there are three periods in the history of luxury,—one in which it is coarse and profuse, a second in which it aims mainly at comfort and elegance, and a third, proper to periods of decadence, in which it is perverted to vicious and unnatural ends. The second of these began, in modern times, with the emergence of the Western nations from the mediæval period, and in the ancient communities at epochs of similar transition. Roscher holds that the sumptuary legislation which regularly appears at the opening of this stage was then useful as promoting the reformation of habits. He remarks that the contemporary formation of strong Governments, disposed from the consciousness of their strength to interfere with the lives of their subjects, tended to encourage such legislation, as did also the jealousy felt by the hitherto dominant ranks of the rising wealth of the citizen classes, who are apt to imitate the conduct of their superiors. It is certainly desirable that habits of wasteful expenditure and frequent and wanton changes of fashion should be discouraged. But such action belongs more properly to the spiritual than to the temporal power. In ancient, especially Roman, life, when there was a confusion of the two powers in the state system, sumptuary legislation was more natural than in the modern world, in which those powers have been in general really, though imperfectly, separated. How far regulation of this kind could, and might usefully, be carried out by a spiritual power under purely moral sanctions, and whether and to what extent social offices, private as well as public, should be discriminated by costume, are questions which need not be discussed at present. Political economists are practically unanimous in their reprobation of the policy of legislative compulsion in these matters. In a well known passage Adam Smith protests against the "impertinence and presumption of kings and ministers in pretending to watch over the economy of private people and to restrain their expense, being themselves always and without any exception the greatest spendthrifts in the society." Yet he does not seem to have been averse to all attempts to influence through taxation the expenditure of the humbler classes. The modern taxes on carriages, coats of arms, hair-powder, playing-cards, &c., ought perhaps not to be regarded as resting on the principle of sumptuary laws, but only as means of proportioning taxation to the capacity of bearing the burden.

The *loci classici* on Roman sumptuary laws are Gellius, *Noctes Atticæ*, ii. 24, and Macrobius, *Saturn.*, iii. 17. On the similar English legislation Henry's *History of Great Britain* may usefully be consulted. One of the best extant treatments of the whole subject is that by Roscher, in his essay *Ueber den Luxus*, republished in his *Ansichten der Volkswirthschaft aus dem geschichtlichen Standpunkte* (3d ed., 1878). (J. K. I.)

SUMY, a district town of Little Russia, in the government of Kharkoff, situated 125 miles to the north-west of the chief town of the government, was founded in 1652 by Little Russian Cossacks. It is poorly built, chiefly of wood, but is an important centre for the trade of Great Russia with Little Russia,—cattle and corn being sent to the north in exchange for various kinds of manufactured and grocery wares. It has a classical pro-gymnasium and a technical school. Its inhabitants, who numbered 16,030 in 1884, are engaged in commerce, in various kinds of petty trades, and in agriculture.

SUN. In the article ASTRONOMY (vol. ii. p. 768 *sq.*) the sun has been considered as a member of the solar system, and references are given to various discoveries which have been made from time to time relating to its physical and chemical constitution. In the present article we propose to consider the sun as a star, and to state as briefly as may be the views at present held regarding its structure, and subsequently to refer to the most recent observations dealing with the physics and chemistry of the various phenomena which are open to our study.

Envelopes. The sun as ordinarily visible to us, bounded by the photosphere, is only a small part of the real sun. from observations made during eclipses it is now known that outside the photosphere are—first, an envelope, namely the chromosphere, which is mainly composed of hydrogen, and outside this another envelope, called the corona, while there is evidence that outside these, and especially along the plane of the sun's equator, there is a considerable extension of matter which may or may not be of the same nature as that of which the corona is composed.

These various parts of the solar economy have been examined by the spectroscope, and from this examination two widely divergent views have arisen.

Extent of sun's atmosphere. According to the first view, the true atmosphere of the sun is limited by the chromosphere, and the constituents of that atmosphere consist essentially of the vapours of the chemical elements recognized on the earth. It will be seen that on this view the corona and the equatorial extension observed occasionally are merely solar appendages. In the other view the atmosphere of the sun is extended to the confines of the corona, the temperature naturally increasing as we descend, and it is held that towards the photosphere the temperature is so high that the chemical elements are dissociated into finer forms of matter, so that descending vapours get more simple, ascending vapours get more complex, and it is only in the cooler regions of the atmosphere that vapours resembling those of our terrestrial elements can exist, while near the confines of the corona these vapours give place to solid particles and masses. Broadly stated, these divergent views have arisen from the application of two distinct methods of inquiry. In one method, light coming from every portion of the sun, and reflected, let us say, by a cloud into the spectroscope, gives us a spectrum full of absorption lines, and these lines are practically constant from year to year. In the other method, each minute portion of the solar economy has been examined bit by bit, and thus we have the spectrum of the spots, the spectrum of the prominences, the spectrum of the chromosphere, the spectrum of the corona. All these spectra vary enormously, not only among themselves, but from year to year, and, when we consider merely the spots and prominences, we may say that they vary from spot to spot and from prominence to prominence.

Mean density. It will be obvious that the true mean density of the sun cannot be the same on the two hypotheses to which we have referred. If the atmosphere is practically limited by the photosphere, it has been found that the density of the sun is 1.444, water being taken as unity. If we include the corona in the sun's atmosphere, and assume that its height is half a million of miles above the photosphere, then the volume of the sun is ten times that bounded by the photosphere, and the density is reduced to a tenth of the value given above.

We next proceed to discuss the chemical results obtained by the first method of inquiry to which reference has been made. For these results we are of course dependent upon comparisons of the lines given by various incandescent vapours with the Fraunhofer lines seen in the ordinary spectrum of the sun. If by such means complete evidence is afforded of the existence of one of our chemical elements in the sun, it is obvious that no information is given as to its precise locality; further, if the high temperatures used in our laboratories to produce a spectrum should break up the molecules of the vapours as known to the chemist into finer ones, and if the temperature of the sun were to do the same, there would still be a considerable similarity between the solar and the terrestrial spectrum of any one substance.

Chemical constitution of atmosphere. The first (A) of the following tables gives the substances present in the sun's atmosphere according to (1) Kirchhoff, and (2) Ångstrom and Thalén.

TABLE A

Kirchhoff	Sodium, Iron, Calcium, Magnesium, Nickel, Barium, Copper, Zinc
Ångstrom and Thalén	Sodium, Iron, Calcium, Magnesium, Nickel, Chromium, Cobalt, Hydrogen, Manganese, Titanium

A subsequent method of inquiry, which was capable of tracing merely a small quantity, gave the additional substances shown in Table B.

TABLE B

Elements whose Longest Lines coincide with Fraunhofer Lines

Certainly coincident	Aluminium, Strontium, Lead, Cadmium, Cerium, Uranium, Potassium, Vanadium, Palladium, Molybdenum
Probably coincident	Indium, Lithium, Rubidium, Cæsium, Bismuth, Tin, Silver, Glucinum, Lanthanum, Yttrium or Erbium

When we come to bring the chemical evidence together which has been acquired by the examination of separate parts of the solar economy, we find, as has been already hinted, that the apparent similarity in chemical structure suggested by the foregoing tables entirely breaks down. Not only is the chemical nature of each separate solar phenomenon different from that of any other, but the facts of observation are in all cases entirely new and strange, so that very little light is obtained towards the understanding of them from ordinary laboratory work.

We will consider the chemistry of the chief solar features in order.

Chemistry of the Constituent Parts

Spectra of spots

The spectrum of the spots differs from that of the ordinary surface of the sun chiefly by the widening of certain of the Fraunhofer lines in the spot spectrum,—some being excessively widened. The lines which are most widened change from spot to spot and from year to year. The most extensive sun-spot observations of this nature have been carried on in Kensington, and the conclusions derived from 700 observations on spots between 1879 and 1885 are as follows:—

(1) The spot spectra are very unlike the ordinary spectrum of the sun: some Fraunhofer lines are omitted, new lines appear, and the intensities of the old lines are changed.

(2) Only very few lines, comparatively speaking, of each chemical element, even of those which have many among the Fraunhofer lines, were seen to be most widened. It was as if on a piano only a few notes were played over and over again, always producing a different tune.

(3) An immense variation from spot to spot was observed between the most widened lines seen in the first hundred observations. Change of quality or density will not account for this variation. To investigate this point the individual observations of lines seen in the spectrum of iron were plotted out on strips of paper, and an attempt made to arrange them in order, but without success, for, even when the observations were divided into six groups, about half of them were left outstanding.

(4) If we consider the lines of any one substance, there is as much inversion between them as between the lines of any two metals. By the term "inversion" is meant that of any three lines, A, B, C, we may get A and B without C, A and C without B, B and C without A.

(5) Very few lines are strongly affected at the same time in the same spot, although a great many lines of the same substance may be affected, besides the twelve recorded as most widened on each day.

(6) Many of the lines seen in the spots are visible at low temperatures (some in the oxy hydrogen flame), and none are brightened or intensified when we pass from the temperature of the electric arc to that of the electric spark.

(7) Certain lines of a substance have indicated rest, while other adjacent lines seen in the spectrum of the same substance in the same field of view have shown change of wave length.

(8) A large number of the lines seen in spots are common to two or more substances with the dispersion employed.

(9) The lines of iron, cobalt, chromium, manganese, titanium, calcium, and nickel seen in the spectra of spots are usually coincident with lines in the spectra of other metals with the dispersion employed, whilst the lines of tungsten, copper, and zinc seen in spots are not coincident with lines in other spectra.

(10) The lines of iron, manganese, zinc, and titanium most frequently seen in spots are different from those most frequently seen in flames, whilst in cobalt, chromium, and calcium the lines seen in spots are the same as those seen in flames.

(11) Towards the end of the first series of investigations there appeared among the most widened lines a few which are not represented, so far as is known, among the lines seen in the spectra of terrestrial elements. This change took place when there was a marked increase in the solar activity.

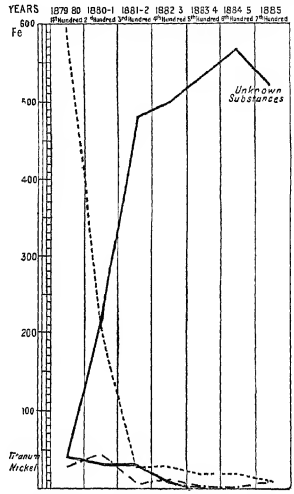
(12) The most widened lines in sun spots change with the sun-spot period.

(13) At and slightly after the minimum the lines are chiefly known lines of the various metals.

(14) At and slightly after the maximum the lines are chiefly of unknown origin.

(15) On the hypothesis under discussion the change indicates an increased temperature in the spots at the sun spot maximum.

The general result is that in passing from minimum to maximum the lines most affected change from those of the ordinary chemical elements to lines whose significance are not known. The accompanying diagram represents graphic- Changes in sun spot spectra



Most widened lines, F – b region, in sun spot spectra

ally the disappearance of the lines of iron, nickel, and titanium and the simultaneous appearance of unknown lines in the spot spectra in passing from minimum to maximum. In the region of the spectrum for which the curves are drawn six lines were recorded in each observation, and therefore 600 in each series of 100 observations. In the curves the vertical ordinates represent not merely the number of individual lines recorded but the number of occurrences of lines of each substance. The dotted curve shows the variation in the frequency of the iron lines; at the minimum in 1879 practically all the 600 lines observed were iron lines, towards the end of 1881 they had dwindled down to 30, and during the three following years they fell to 10. The dot and dash curve shows a similar variation in the nickel lines, and the double line curve that of the titanium lines during the same periods. The continuous curve shows the gradual increase in the number of occurrences of unknown lines in passing from the minimum in 1879 to the maximum in 1884.

Chromosphere

The chromosphere when quite quiescent merely gives us a spectrum of hydrogen together with a line in the yellow, which, from its proximity to D_1 and D_2, is called D_3. The chromosphere is disturbed in two ways,—first, by prominences, of which more hereafter, and second, by the formation gradually and peacefully of domes, which are of no great height but sometimes extend over large areas and last for weeks. These last-named phenomena have been termed "wellings up," the idea being that they were produced by the gradual uprise of vapours from below, but it is clear that the same phenomena might be

produced by the very slow descent of matter from above The spectrum of these higher portions of the chromosphere, whether produced from below or above, is more complicated than the ordinary one The following table (C) gives the principal lines which have been recorded up to 1887 —

1869	Hydrogen D_3	All lines	
	1474 (5315 9)	Unknown	
	b^1 b^2 b^4	Magnesium,	3 out of 7 (Thalén)
	b^3	Nickel,	1 ,, 34
	D_1 D	Sodium,	2 ,, 8
	4933 4 4899 3	Barium,	2 ,, 26
	4923 1 5017 6	Iron,	2 ,, 460 (Ångstrom)
	5275 5233 6 5179 9 4921 3 5014 8 bright	Unknown	
After 1869	f4471 4924 5 B—C B—a	Unknown	
	5019	Titanium,	1 out of 201 (Thalén)
	H K	Calcium,	2 ,, 74

The first new line in this table is called in spectroscopic language 1474, because when this work was begun the only maps available were those made by Professor Kirchhoff, and this particular line fell at 1474 on his scale Since then these artificial scales have been discarded in favour of the natural one, which is given by the wave-lengths of light of different colours In this the reference number of the same line is 5315 9, which represents the wave-length in ten-millionths of a millimètre of that particular quality of light After this we observe three lines of magnesium, only 3 out of 7, next a line of nickel, one only, however, out of 34, then two lines of sodium, although we might naturally expect to get all the 8 lines, then two lines of barium out of 26, and so on Almost all the other lines have origins which are absolutely unknown that is to say, we never get them in our terrestrial laboratories, and never, therefore, are able to match the bright lines in the chromosphere of the sun with any chemical substance In 1871 the sun was more active, and this activity resulted in the addition of new lines, all, however, absolutely unknown to us, except one, which represents a line in the spectrum of titanium, but in that case we get one line out of 201 in exactly the same way as we get two only of iron out of 460 It is most important to note that practically none of the lines shown in table C are among those which are widened in spots

Prominences The prominences are of two kinds—those which are relatively quiet and give almost exclusively the lines of hydrogen and those in which the motions are as a rule very violent The spectrum of the latter class generally includes a large number of metallic lines, hence they are generally called metallic prominences The first stage of metallic prominence is usually the appearance of three lines of the following wave-lengths—4943, 5031, 5315 9 As the prominence increases in magnitude and violence other lines are added, until at times the spectrum seems full of lines The rate of uprush of these prominences sometimes reaches 250 miles per second, or nearly a million miles an hour,—figures which convey an idea of the enormous energies involved The lines seen in these prominences, although many are present in the spectra of the metallic elements, appear with greatly changed intensities the lines seen brightest in the prominences are frequently dim lines in the terrestrial spectrum Again it may be remarked that these are not the lines which are most widened in spots In the case of the spectrum of any one substance the number of lines seen usually in the prominences is very small

The general conclusions which have been derived from a discussion of the prominence observations made by Profs Tacchini and Riccò, in connexion with the sun-spot observations already mentioned, are as follows

(1) The chromospheric and prominence spectrum of any one substance, except in the case of hydrogen, is unlike the ordinary spectrum of the substance For instance, we get two lines of iron out of 460

(2) There are inversions of lines in the same elements in the prominences, as there are inversions in the spots in certain prominences we see certain lines of a substance without others, in certain other prominences we see the other lines without the first

(3) Very few lines are strongly affected at once, as a rule, and a very small proportion altogether,—smaller than in the case of spots

(4) The prominences are less subject to sudden changes than spots, so far as lines of the same element are concerned

(5) There is a change in the lines affected according to the sun's spot period

(6) The lines of a substance seen in the prominences are those which in our laboratories become considerably brightened when we change the arc spectrum for the spark spectrum

(7) None of the iron lines ordinarily visible in prominences are seen at the temperature of the oxy hydrogen flame Some of the oxy hydrogen flame lines are seen in the spots, but none have ever been seen in the prominences

(8) A relatively large number of the lines ordinarily seen are of unknown origin

(9) Many of the lines seen are not ordinarily seen amongst the Fraunhofer lines Some are bright lines

(10) As in the spots the H and K lines of calcium in the ultra-violet are always bright in the spot spectrum, the other lines of calcium and the other substances being darkened and widened, so it would appear that the lines H and K of calcium are always bright in the prominences in which the other lines are generally unaffected

(11) Many of the lines are common to two or more elements with the dispersion which has been employed

Corona The spectrum of the inner corona indicates that it is chiefly composed of hydrogen All the hydrogen lines are seen in it, and up to a certain height the H and K lines of calcium, proving the presence either of calcium or of something that exists in calcium which we cannot get at in our temperature

In the outer corona most of the hydrogen lines disappear, but one, the green line F, remains for a considerable height side by side with the 1474 line, indicating, as far as we can see where everything is so doubtful, that the constituents of the outer corona consist most probably of hydrogen in a cool form and the unknown stuff which gives the 1474 line We also know that the outer corona contains particles which reflect the ordinary sunlight to us, because in 1871 Dr Janssen, and in 1878 Professor Barker and others, saw the dark Fraunhofer lines in the spectrum of the corona We must imagine, therefore, that some part of that spectrum depends for its existence on solid particles which not only give a spectrum like that of the lime-light but have the faculty of reflecting to us the light of the underlying photosphere It was also put beyond all question in the eclipse of 1882 in Egypt that this corona has another spectrum of its own. There are bright bands in the spectrum, showing that with these additions it is not a truly continuous spectrum like that of the lime light, and that its origin is therefore in all probability very complex

Association and Distribution of Phenomena

Connexion of phenomena Observations of prominences, spots, and other phenomena which require continuous investigation have been carefully made from day to day for several years, and one conclusion arrived at is that when and where the (disturbed) spots are at the maximum the faculæ and metallic prominences are also at the maximum When the maximum changes from north to south latitude in the spots it also changes from north to south in the metallic

prominences and the faculæ These observations, therefore, establish not only an important connexion between spots, metallic prominences, and faculæ but also the fact of the wonderful localization of these phenomena upon the sun The spots are never seen higher in latitude than 40° north or south, and they are invariably seen in smaller quantity at the equator Similarly, the faculæ and metallic prominences do not go much beyond 40° north or south, and their minima are also at the equator But this does not hold good for prominences of the quiet sort and the veiled spots,—that is, spots without umbræ or very highly developed penumbræ They extend from one pole of the sun to the other, hence there must exist a great difference between metallic and quiet prominences and between disturbed and veiled spots

Association of localized phenomena

Although the more important of these solar phenomena are limited to certain zones of the sun's surface, and although they vary very violently, they have a cycle or regular succession of changes, during which the particular zone of the sun on which they appear alters When there is the smallest number of spots on the sun—that is to say, when there is a sun-spot minimum—the spots that appear are seen in a high latitude, and the latitude decreases gradually until we arrive at the next minimum Thus there are two perfectly distinct spotted areas, one corresponding to the end of the old period, the other to the beginning of the new period At the maximum period of sun spots the latitude of the spot zone is about 15° Activity in the solar atmosphere, therefore, appears to begin in a high latitude—say about 30° or 35°—and very soon reaches the maximum in about latitude 15°, then it gradually dies away until spots, metallic prominences, and faculæ—all of reduced intensity—cling pretty near to the solar equator, and at the same time we get a new wave of activity, beginning again in a high latitude This association of what may be called localized phenomena is quite in harmony with a similar association of phenomena which are more or less generally distributed over the whole surface of the sun

Pores, which are in reality nothing but small sun spots, may occur in any part of the sun, and are always accompanied by a slight waviness in the chromosphere Veiled spots—spots which never attain full development—are also universally distributed over the sun's surface and are accompanied by small prominences (see below)

Period of solar quietude

The main periodicity on the sun is that of about eleven years which elapses between two successive maxima or minima When the sun is quietest, there are very few of the ordinary tree-like prominences visible, and there is an especial dearth of them near the poles and the equator There are faculæ, but they do not present their usual bright appearance, and are confined to the regions between latitudes 20° N and 20° S On examining the chemical nature of the materials in the chromosphere at such a period by means of a spectroscope, we see only the four lines of hydrogen and the line D_3, whose chemical significance we do not know Practically speaking, there are no spots visible and the disk appears to be perfectly pure, except the darkening towards the limb produced by absorption in the sun's atmosphere As there are no spots, or only very small ones in high latitudes, it follows that there are no metallic prominences The spectroscope searching right round the limb of the sun gathers no indications of violent action—no region giving many lines—nothing but the simple spectrum of hydrogen Observations and photographs of the corona taken at solar eclipses occurring at minimum spot periods indicate that at two different sun-spot minima the appearances presented by the corona are very much alike. A drawing made during the eclipse of 1867, before the application of photography to solar investigations, exhibits a similar appearance to an absolutely trustworthy photograph obtained at the eclipse of 1878 At the minimum period the chief feature is a very great extension of the corona in the direction of the solar equator, and a wonderfully exquisite outcurving right and left at both poles It is probable that the equatorial extension pictured in the above-mentioned photograph is, after all, only a part of a much more extended phenomenon, one going to almost incredible distances from the sun itself At the eclipse of 1878 precaution was taken to shield the eye of the observer from the intense light of the inner corona, which is sometimes so bright as to be mistaken for the sun's limb, by erecting a screen which covered the moon and a space 12′ high around it The observer, Professor Newcomb, saw on both sides of the dark moon a tremendous extension of the sun's equator, far greater than that recorded in the photographs taken at the same time But the extended portions may have been so delicately illuminated that they could not impress their image on the photographic plate during the time it was exposed, or that the light itself is poor in chemically active rays The extension, as observed by the shielded eye, amounted to six or seven times the diameter of the dark moon In a more favourable situation the same extension, but to a less extent, was observed without the aid of a screen At a sun-spot minimum, therefore, there exists a great equatorial extension of the corona east and west

Transition to maximum period

The time between the minimum and the maximum sun-spot periods is three or four years, and that from maximum to minimum seven or eight years, so that the sun increases in activity much more rapidly than it afterwards decreases in passing to the next minimum Starting, then, about half way between minimum and maximum, we find an increased activity in every direction The quiet prominences, consisting of hydrogen, are more numerous, and the faculæ are brighter If at this time we examine the spectrum of the chromosphere, we find hydrogen and D_3 are not the only constituents we get other short lines, the chief being the three lines of magnesium b_1, b_2, b_4 The spots are more numerous and are in a lower latitude, having moved from near 35° to about 25° Metallic prominences now constantly accompany the spots, and the number of bright lines visible in their spectra gradually increases from month to month These changes are accompanied by changes in the corona, which affect not only its form but also its spectrum At the minimum spot period the corona gives an almost continuous spectrum, differing only in the presence of a few dark lines, and occasionally a few not very obvious bright lines, whence we conclude that at the minimum the corona is not entirely gaseous In passing from the minimum to the maximum the spectrum is no longer continuous bright lines begin to appear, emanating from the incandescent gaseous portions of the corona, and at the same time there is an increase in brilliancy At this period there is no longer any remarkable equatorial extension, although here and there streamers of strange outlines occur A drawing of the eclipse of 1858, a period between minimum and maximum, shows in middle latitudes, both north and south, four remarkable luminous cones standing with their bases on the chromosphere The amount of light and structure in the corona has increased to such an extent that the beautiful double curves seen at the poles at the minimum are now hidden in a strong radiance

Maximum period.

During the maximum period all the solar forces are doing their utmost, and we see in prominences and spots, and indeed in every outcome of action that we can refer to, indications of the most gigantic energies being at work The ordinary prominences, instead of clinging to

the equator, now occur most frequently at the poles. The faculæ are brighter and are more widely distributed, and the chromosphere is richer in lines. The spots at this period occupy broad zones with mean latitudes of about 18° N. and 18° S. There are no spots near the poles and none near the equator, but large spots, indicating a state of violent agitation, surrounded by gigantic faculæ, follow each other in these zones. Each of these indicators of solar activity is accompanied by a prominence. At this time also we note the greatest velocities of down-rush in the vapours which form the spots and of up-rush in those which form the prominences. These changes are accompanied by corresponding changes in the corona, and, fortunately, we have photographic records for two periods of maximum,—1871 and 1882. In these the streamers, instead of being limited to the equator or to mid-latitudes, exist in all latitudes, so that they practically extend to every part of the sun. Their directions, which may be called lines of force, are very varied, some being straight and some curved, but it is difficult to unravel the appearances, because what we see are only projections of the actual things, and this is especially the case when the sun's pole is tipped towards or away from the earth to the greatest extent. In the eclipse of 1882 the corona indicated a more equal distribution of action than that of 1871, but the general result was the same.

After the maximum period there is a gradual falling off of all the various energies, the mean latitudes of the spots decreasing until they reach 8° N. and 8° S., then another series of spots breaks out about 35° N. and 35° S. lat., and the cycle begins anew.

General Theory.

General theory. It has been very generally accepted for some time that sun-spots are depressions in the photosphere, produced by downfalls of cool material. The following sketch shows how, if we accept this view and also the hypothesis that the chemical elements are dissociated in the lower parts of the solar atmosphere, many of the more important solar phenomena may be explained and correlated.

We know that small meteorites in our own cold atmosphere are heated to incandescence by friction, that is, by the conversion of their kinetic energy into heat, and it is therefore not difficult to imagine that enormous masses, falling with great velocities through the sun's highly heated atmosphere, would be competent to give rise to such disturbances as those with which we are familiar on the sun's surface. This cool material is produced by the condensation, in the upper cool regions of the sun's atmosphere, of the hot ascending vapours produced at the lower levels, and this is probably the main source of supply of spot-producing material. The faculæ and other disturbances of the general surface do not precede but follow the formation of a spot, so that a spot may be considered as the initial disturbance of the photosphere in the region where it is observed. Large spots almost invariably appear first as little dots, frequently in groups, and then suddenly grow large. The little dots, according to the view of spot formation now under discussion, are formed by small masses which precede the main fall. The heat produced by friction with the atmosphere and the arrested motion causes up-rushes of heated vapours, which eventually cool and condense, and afterwards fall to the photosphere and produce fresh disturbances. Down-rushes of cool material must take place all over the sun's surface, and, although the most violent results of such falls are restricted to certain regions, minor disturbances are distributed over the whole surface. These generally distributed phenomena are well known to be merely different degrees of the same kind of energies that operate in producing the more restricted ones.

We will now review the several phenomena in turn, beginning with the most widely distributed.

Besides the general darkening near the edge of the sun's disk, the surface is seen to be strangely mottled near the poles, near the equator, and in fact universally. Moreover, small black specks, called *granulations* or *pores*, are everywhere visible, and spectroscopic examination shows that every one of these is a true spot. The fine mottlings frequently indicate the existence of powerful currents in that they take definite directions, sometimes in straight lines, sometimes in lines suggesting cyclonic swirls. In addition to the pores spots of a smudgy kind, called *veiled spots*, are sometimes seen, and it is probable that in such cases the force of the down-rush is insufficient to depress the photosphere to an extent competent to give rise to the ordinary dark spots. Some spots appear as large pores, that is, they consist of nothing but umbra; others appear as well developed veiled spots, consisting almost entirely of penumbra. The obvious large spots consisting of umbra and penumbra follow next in order of intensity, and, as has been previously pointed out, their appearance is confined to definite spot zones. Minute observation, therefore, shows that the whole of the sun's surface is traversed by down-rushes of varying intensities, from almost infinitesimal dimensions to the most powerful that we can conceive. Some of the ordinary spots do not appear to be in any violent state of agitation; the penumbra and umbra are well defined, and the ridge of faculæ round such a spot does not indicate any disturbance by either lateral or convexion currents. Other spots, however, indicate very violent commotion, the penumbra and umbra being tremendously contorted and mixed up. In this kind of spot the disturbance often affects enormous areas of the sun's surface; one spot in 1851 was 140,000 miles across, and the commotions were so great that they could be detected by eye observation with the telescope. It appears as if the material carried in the first instance below the level of the photosphere produces a disturbance in the interior regions, which exhibits itself at the surface by an increase in the quantity and brilliancy of the surrounding faculæ. As a spot dies away it is replaced by faculæ, and these remain long after the spot has closed up. It often happens that new spots break out in the places occupied by previous spots. The spot producing material in its descent is dissociated either before or when it reaches the photosphere, and the rapidity and energy of the dissociation depend upon the velocity with which it travels. Gravitation is of course the main factor operating in the production of a down-rush. The velocity produced by gravitation in matter falling from great heights above the photosphere must be very great, and in consequence the kinetic energy of the moving mass must also be great. The motion is impeded by friction with the gases in the sun's atmosphere, and some or perhaps all the kinetic energy becomes heat. The heat thus developed must produce sudden expansions, and the initial down-rush is surrounded by up-rushes along the lines of least resistance. The effects of such down-rushes vary in degree according to the quantity of matter falling and the height from which it falls. Effects of down-rush.

Equally too there are observed different degrees of the effects of up-rushes. All over the sun's surface are seen domes of faculæ, either separate or in groups, and there is indication that they are hotter than the rest of the surface, for the bright lines of hydrogen are seen to surmount them. It is probably owing to this that the chromosphere exhibits a billowy outline when under conditions of little disturbance. The next condition of increased action exhibits itself in the growing complexity of the chemical nature and of the form of the chromosphere. Occasionally the whole level of the chromosphere over a large region seems to be quietly raised, and observation proves this to be due to the intrusion of other vapours. There is either a gradual evaporation from the photosphere or a gradual vaporization or expansion of slowly falling material over large regions, raising the level of the sea of hydrogen. The chromosphere then appears to contain different layers, and the lower we descend towards the photosphere the less we know about the substances that exist there. The next degree of disturbance is seen in what are called the *quiet prominences*, which very frequently occur in regions where the beginning of a disturbance has been previously indicated by the appearance of domes and metallic strata. As a rule the quiet prominences are not very high—not higher than 40,000 miles—and many of them resemble trees. They are almost entirely composed of hydrogen, or at least of a substance which gives some of the lines observed in the spectrum of hydrogen. Such a prominence grows upwards from the photosphere, being first of a small height, then getting higher and often broader, and finally a kind of condensation cloud may form at the top. The upward velocity of the gases forming these prominences is seldom very great. When a prominence disappears it does not follow that the substances of which it was composed have also disappeared, and there is evidence to show that the apparent disappearance is due to a reduction of temperature. The most intense degree of action of an up-rush is exhibited by the metallic prominences, which Effects of up-rush.

contain other substances in addition to hydrogen. They are seen mounting upwards to enormous heights with almost incredible velocities, and their ascent is accompanied by violent lateral motions. Such prominences have been seen with an upward velocity of 250 miles a second, and of a height as great as 400,000 miles. There is also evidence that some prominences consist of mixed up-rushes and down-rushes, and it may turn out eventually that this is the case in all the metallic prominences.

Inter-relations of phenomena. According to the gravitation-dissociation theory of the formation of spots, we ought to find that the effects, in various degrees, produced by down-rushes of associated matter are related to the effects, in like degrees, produced by the corresponding up-rushes of dissociated materials. Comparing, then, the facts already stated, we have:—

Effects of Down-rush	Effects of Up-rush
1. Pores	1. Domes
2. Veiled spots	2. Metallic strata and small prominences
3. Quiet spots	3. Quiet prominences
4. Disturbed spots	4. Metallic prominences

It is a fact that the pores and domes are very closely associated over all parts of the sun, and that the domes are most prominent in places previously occupied by spots. All large spots are seen to be accompanied by metallic prominences, when observed at the edge of the sun. There is also a strict relationship between the intensity of action going on in a spot and the associated prominence, so much so that a very violent change in a spot on the disk sometimes causes the bright prominence lines to become visible in its spectrum. The ordinary metallic prominences, as already stated, may consist of both ascending and descending material; this will be best understood by likening the whole phenomenon to a splash.

Physics of a sun-spot cycle. We have previously seen that spots and metallic prominences are very intimately connected as regards their occurrence in zones, and this intimacy is easy to explain by supposing things to happen in the way here set forth. The height of the solar atmosphere is greater over the equator than at the poles; particles condensed on the outside at the poles have therefore a relatively small velocity when they fall into the photosphere, and are able to produce only pores or veiled spots. Over the equator the particles attain a higher velocity in their fall, but they also have to pass through a much greater thickness of atmosphere and undergo so much dissociation that on reaching the photosphere they are incompetent to produce spots. In mid-latitudes, therefore, the falls of condensed particles should be most effective in producing spots. In this way the absence of spots at the poles and equator is explained,—one of the best known facts of solar physics. The falls of the condensed particles, or meteoric matter, into the sun increase the temperature of the atmosphere over the spots and prominences which they produce, so that other falls in the same region are not effective in producing spots on account of the increased dissociation which they must undergo before reaching the photosphere. If the material condensed in those regions is to produce a spot, it must be removed to some place where it can reach the photosphere without being dissociated. Hence from the first appearance of spots after a sun-spot minimum there is a continual change of latitude. From minimum to minimum there is a regular decrease in the latitude of spots; hence it is clear that there must be currents from the poles towards the equator in the upper atmosphere of the sun, causing the removal of condensed materials to lower and relatively cooler latitudes. Assuming the existence of such currents, we ought to find that successive spots have a tendency to form along the same meridians, for the polar currents would carry the condensed materials to lower latitudes in a nearly meridional direction. Examination of sun-spot records for 1878–79 shows that there is a marked tendency for spots to follow each other in meridians. The existence of such currents is further supported by the outcurving of the corona at the solar poles as observed in several eclipses. If these currents exist, there must also be compensating currents towards the poles in the lower parts of the sun's atmosphere, carrying incandescent vapours along with them. Small prominences often give indication of motion towards the poles which such currents would produce, and examination of sun-spot records also shows that the tendency of the proper motion of the spots is polewards. Hence, although the existence of these currents has not been definitely proved, there is strong evidence that there exists some circulation of this nature in the solar atmosphere.

When once the falls have commenced, if this hypothesis is true, they should rapidly increase in intensity, for, as it is the falls which increase the temperature of the lower atmosphere by the conversion of their kinetic energy into heat, the more falls there are the more material will be taken first to the poles and then towards the equator, and therefore there will be more available spot-forming material. But we know that this increase in intensity does not go on for ever, and there must therefore be some regulating influence. The increase of temperature and possibly of the height of the solar atmosphere, due to the increased falls, will eventually become such that the descending materials are dissociated before they reach the photosphere. The production of spots must therefore gradually diminish until they finally disappear and end the spot cycle. At the minimum period, therefore, pores and veiled spots, due to less powerful energies, are at a maximum.

Eclipse observations. Records of eclipses, occurring when the sun was quietest, show that the condensing and condensed materials brought to the equator by the polar currents probably extend far beyond the true atmosphere of the sun and are there collected, possibly in the form of a more or less regular ring the section of which widens towards the sun, the widest part being within the boundary of the sun's atmosphere. If we assume such a ring under absolutely stable conditions, there will be no fall of material, and therefore no prominences or spots. But suppose a disturbance caused, as before, by collisions, which most likely occur where the particles brought by the polar currents meet the surface of the ring. These particles then fall from where the ring first meets the atmosphere on to the photosphere, and form the first spots. Eclipse records show that this action takes place about 30° lat. According to this view, there are usually no spots above 30° lat., because there is no ring, and because the atmosphere is too low to give the height of fall necessary to produce spots. There are no spots at the equator for the reason that the condensed matter has to pass for perhaps millions of miles through strata of increasing temperature, and do not therefore reach the photosphere before being dissociated. Accordingly, we ought to find that at and after the maximum the corona is brighter and more truly a gaseous body on account of the increased temperature. This is in strict accordance with eclipse observations extending over twenty years. According to this view of the solar economy, the sun ought to give out more heat at a maximum than at a minimum period, when the number of falls is greatest; on this point see the article METEOROLOGY (vol. xvi. p. 167 sq.).

The Sun's Place among the Stars.

The relative nearness of the sun makes it convenient as a type of those stars which on account of their great distance are less accessible to minute observation. If the sun were at a greater distance, its spectrum would become much fainter and would not show so much detail, but its general character would not be altered: its dark lines would not become bright ones. In the atmospheres of the various members of the solar system, including the earth, there is a very considerable absorption of blue light. We know also that this condition applies to the sun.

Star absorption of light. The light we receive under present conditions we call white; but, if its own atmosphere and ours were removed or became so changed as to no longer absorb blue light, the sun would appear blue. If, on the other hand, the blue absorption were enormously increased, so that it extended into the green, the sun would appear red, because every other kind of light would be absorbed. If two kinds of absorption—one in the red, the other in the blue—were going on together, as they sometimes do in our laboratories, the sun would then appear green. Although these changes are not of actual occurrence in the sun, we find each of these conditions represented among the stars. In the coloured stars, which may be red, green, or blue, we are simply dealing with this kind of absorption phenomena. This difference in the conditions of absorption in the stars, however, is by no means the most important one: the difference of temperature as indicated by the spectrum is of primary importance. As in our laboratories the spectrum of a substance is changed by a variation of temperature, and always in a regular way, so the nature of a star's spectrum furnishes a clue to its probable state as regards heat. For example, we may submit carbon vapour to a low temperature, and we shall then obtain what is called a spectrum of flutings; on increasing the temperature, the flutings are replaced wholly or partially by lines, according to the amount of increase. From hundreds of observations of this kind, both on carbon and other substances, it may be safely inferred that a fluted spectrum indicates a lower temperature than a line spectrum. There are doubtless substances in the sun's atmosphere which, although represented by lines in its

spectrum, can be submitted to low conditions of temperature so as to give fluted spectra There can be little doubt, therefore, that a cooling of the sun would be followed by a change in its spectrum, which would cease to be one of lines and become one of flutings While the sun was acquiring its present intensely heated state, it must at some period of its history have been in a condition of temperature in which its spectrum would consist of flutings, and similarly it must give a fluted spectrum at some future period when it has further cooled

Solar radiation and spectra

The ordinary Fraunhofer spectrum gives the sum total of the line absorptions of all the various layers in the sun's atmosphere, but by examining individual layers just off the edge of the disk we can single out the absorption lines produced by the lower layers Thus the absorption produced by the hottest layer, the chromosphere—hottest because nearest the photosphere—is indicated by its usually simple radiation spectrum when examined in this way If the sun were made hotter, therefore, the gases which give the simple chromosphere spectrum would have a larger share in the absorption, and the main features of the Fraunhofer spectrum would be the few dark lines corresponding to these bright ones This being so, a star which gives practically the same absorption spectrum as the chromosphere of the sun must be hotter than the average temperature of the sun's atmosphere,—as hot as the hottest part of it The bright central part of the sun is not very much less than the whole volume, but it is so much hotter that it gives out thousands of times more light than the atmosphere The cool vapours in the atmosphere give the dark Fraunhofer lines by their absorption, and even if they are hot enough to give bright lines when seen on the sun's edge they can only reduce the intensity of the dark lines Here the difference of area between the disk representing the central mass and that representing the sun's atmosphere is very small, and, the light from the central mass being so much more intense, we do not ordinarily see the evidences of radiation, but, in place of it, the absorption of the atmosphere If, however, we suppose the central mass to be very small compared with its atmosphere, the total radiation of the atmosphere may be sufficiently powerful to overcome the intensity of the light from the smaller central part, so that the spectrum of such a star would contain bright lines from the exterior mixed up with the dark lines from the interior The spectrum of a star, therefore, does not always depend upon its total diameter, but upon the relative diameters of the central mass and the outer atmosphere It is a question of sectional areas

Stellar spectra

Observations of the spectra of a large number of stars show that, although there is a great difference between individual spectra, they still admit of arrangement in family groups While some stars give line absorption spectra, others give fluted spectra, and others again give bright lines They may be conveniently arranged as follows —

		Example
Class I	Stars whose spectra consist of a few thick absorption lines	α Lyræ
Class II	Stars whose spectra consist of a large number of fine absorption lines	Sun, Capella, &c
Class III	Stars with fluted spectra, the maxima of the flutings being towards the red	152 Schj
Class IV	Stars with fluted spectra, the maxima being towards the blue	α Orionis
Class V	Stars whose spectra contain bright lines,—(a) of hydrogen, (b) of unknown substances	β Lyræ

This classification probably represents the stars in order of temperature, class I being the hottest

Although different stars may contain lines of identical wave-lengths, the thickness of these lines is very liable to variation in passing from one star to another The thickest lines in the solar spectrum are H and K in the ultra violet, both of equal thickness, on passing to some of the stars, however, we find H broad with K thin, and in others H without K This is similar to what occurs in our laboratories when we study the spectrum of calcium, the substance which gives the lines H and K at the temperature of the electric arc the blue line of calcium is very intense, while H and K are scarcely visible, but on passing to a higher temperature, that of the induction spark, H and K appear In those stars which give H without K, namely, those in class I, it is probable that there is a very high temperature competent to separate H and K, just as H and K were conjointly separated from the blue line A further indication of high temperature in the stars belonging to class I is that the few lines which do occur in their spectra are almost the exact counterparts of those which occur in the hottest layer of the sun, hydrogen lines being especially prominent The passage from class I to class II is by no means sudden there are stars with every gradation of broad and fine lines It will readily be understood that the stars of class II are probably not so hot as those belonging to class I, and the change in the spectrum is supposed to be due to new combinations of the original substances, rendered possible by a reduction of temperature, that is, new lines are formed at the expense of the old ones The hydrogen lines are very prominent in class II, though not so intense as in class I The stars of these two classes may be grouped together and called hydrogen stars Stars belonging to class III exhibit unmistakable evidence of carbon vapour Sodium and iron are also often present All the stars in this class, of which fifty-five are known, agree in having a reddish tint They are usually faint, and seldom exceed the fourth magnitude There is evidence of the existence of carbon vapour in the sun's atmosphere, depending upon one solitary fluting, and hence stars of this class probably represent what the sun would become if it were cooled Class III therefore represents a lower temperature than classes II and I Class IV, containing 475 known members, includes the stars giving fluted spectra with the darkest edges of the flutings towards the violet The origin of the substances of which they are mainly composed is not at present known All the principal bands are absolutely unchanging in position, although there is considerable variation in the intensities The bands in the spectrum appear to result from the rhythmical vibrations of the same substance, probably a complex one Besides this unknown substance, there are also metallic lines in many of the stars, the complete spectrum consisting of the banded spectrum superposed upon the line spectrum The metallic lines are generally seen in the spectra of sodium, iron, magnesium, or calcium, the hydrogen lines are very inconspicuous

Stellar evolution

These considerations suggest the question of stellar evolution Comets and nebulæ are now supposed to consist of clouds of stones or small meteorites, and the difference between their spectra may be due to a difference of temperature, that of the nebulæ being highest Comets ordinarily give the spectrum of carbon, and, if we imagine such cometary matter to surround a central bright nucleus, we have the spectrum of a star of the third class On the nebular hypothesis, starting with ordinary cometary materials, the small masses resulting from the first condensations gravitate towards each other, and their energy becomes heat by the retardation of their motion on coming in contact As soon as the condensed mass is hot enough, it gives a fluted spectrum, like stars of the third class As the energy of condensation increases, the temperature is raised and the spectrum passes from that of a third class star to that of a second class star, and then to that of a first class star On the subsequent cooling of what is then a star the successive stages will be again passed through in inverse order According to this view, we ought to find fewer hydrogen stars than carbon stars, because every star is a carbon star at two periods of its existence, but a hydrogen star only once On this point, however, nothing definite can be stated, as the stars of classes I and II have, in consequence of their greater brightness, received more attention than carbon stars

New and variable stars

In 1866 a star of the tenth magnitude in the constellation Corona suddenly flashed up into a star of nearly the first magnitude, its spectrum as a tenth magnitude star differed from its spectrum as a first or second,—the latter containing bright lines of hydrogen In about a month it again became a tenth magnitude star and appeared as if nothing had happened to it There can be little doubt that here there was a sudden increase of temperature, as evidenced by the spectrum becoming like that of the chromosphere of the sun Ten years afterwards a new star appeared in Cygnus, it had never been seen before, but appeared suddenly as a third or fourth magnitude star In about a year it gradually dwindled down to the tenth magnitude, and its spectrum became that of a nebula This mass was at a stellar distance, but it cannot be considered to have been a large mass of incandescent material, for in that case it would have taken millions of years, instead of only one, to cool down to the tenth magnitude A possible explanation of most of the new and variable stars is to be found in the meteorite theory the innumerable components of one group of meteorites colliding with those of another group would be competent to give out light sufficient to make the whole appear as a star Each meteorite gives only a little light, but the total must be very considerable The new star in Corona, and similarly all new stars, may have been the result of a collision of two groups of meteorites They die out quickly because the components are small and far apart The sudden increase in the brilliancy of the star in Cygnus would be produced by a collision of a meteor swarm with the star already existing (J N L)

SUN-BIRD, a name more or less in use for many years,[1] and now generally accepted as that of a group of

[1] Certainly since 1826 (cf Stephens, *Gen Zoology*, xiv pt 1, p 229) Swainson (*Nat Hist and Classif Birds*, i p 145) says they are "so called by the natives of Asia in allusion to their splendid and shining plumage," but gives no hint as to the nation or language wherein the name originated By the French they have been much longer known as "Soumangas," from the Madagascar name of one of the species given in 1658 by Flacourt as *Soumangha*

over 100 species of small birds, but when or by whom it was first applied is uncertain. Most of them are remarkable for their gaudy plumage, and, though those known to the older naturalists were for a long while referred to the genus *Certhia* (TREE-CREEPER, *q.v.*) or some other group, they are now fully recognized as forming a valid Family *Nectariniidæ*, from the name *Nectarinia* invented in 1811 by Illiger. They inhabit the Ethiopian, Indian, and Australian Regions,[1] and, with some notable exceptions, the species mostly have but a limited range. They are considered to have their nearest allies in the *Meliphagidæ* (*cf.* HONEY-EATER, vol. xii. p. 139) and the members of the genus Zosterops; but their relations to the last require further investigation. Some of them are called "Humming-birds" by Anglo-Indians and colonists, but with that group, which, as before indicated (HUMMING-BIRD, vol. xii. p. 357), belongs to the *Picariæ*, the Sun-birds, being true *Passeres*, have nothing to do. Though part of the plumage in many Sun-birds gleams with metallic lustre, they owe much of their beauty to feathers which are not lustrous, though yet almost as vivid,[2] and the most wonderful combination of the brightest colours—scarlet, purple, blue, green, and yellow—is often seen in one and the same bird. One group, however, is dull in hue, and but for the presence in some of its members of yellow or flame-coloured precostal tufts, which are very characteristic of the Family, might at first sight be thought not to belong here. Graceful in form and active in motion, Sun-birds flit from flower to flower, feeding chiefly on small insects which are attracted by the nectar; but this is always done while perched, and never on the wing as is the habit of Humming-birds. The extensible tongue, though practically serving the same end in both groups, is essentially different in its quasi-tubular structure, and there is also considerable difference between this organ in the *Nectariniidæ* and the *Meliphagidæ*.[3] The nests of the Sun-birds, domed with a penthouse porch, and pensile from the end of a bough or leaf, are very neatly built. The eggs are generally three in number, of a dull white covered with confluent specks of greenish grey.

The *Nectariniidæ* form the subject of a sumptuous *Monograph* by Capt. Shelley (4to, London, 1876-1880), in the coloured plates of which full justice is done to the varied beauties which these gloriously arrayed little beings display, while, almost every available source of information having been consulted and the results embodied, the text leaves little to be desired, and of course supersedes all that had before been published about them. This author divides the Family into three subfamilies:—*Neodrepaninæ*, consisting of a single genus and species peculiar to Madagascar; *Nectariniinæ*, containing 9 genera, one of which, *Cinnyris*, has more than half the number of species in the whole group; and *Arachnotherinæ* (sometimes known as "Spider-hunters"), with 2 genera including 11 species—all large in size and plain in hue. To these he also adds the genus *Promerops*,[4] composed of 2 species of South-African birds, of very different appearance, and the affinity of which to the rest can as yet hardly be taken as proved. According to Mr Layard, the habits of the Cape Promerops, its mode of nidification, and the character of its eggs are very unlike those of the ordinary *Nectariniidæ*. In the British Museum *Catalogue of Birds* (vol. ix. pp. 1-126, and 291) Dr Gadow has more recently treated of this Family, reducing the number of both genera and species, though adding a new genus discovered since the publication of Capt. Shelley's work. (A. N.)

[1] One species occurs in Baluchistan, which is perhaps outside of the Indian Region, but the fact of its being found there may be a reason for including that country within the Region, just as the presence of another species in the Jordan valley induces zoographers to regard the Ghór as an outlier of the Ethiopian Region.

[3] *Cf.* Gadow, *Proc. Zool. Society*, 1883, pp. 62-69, pl. xvi.

[4] According to Brisson (*Ornithologie*, ii. p. 460), this name was the invention of Réaumur. It seems to have become Anglicized.

SUN-BITTERN, otherwise the CAURÂLE,[5] the *Eurypyga helias* of ornithology, a bird that has long exercised systematists and one whose proper place can scarcely yet be said to have been determined to everybody's satisfaction.

According to Pallas, who in 1781 gave (*N. nördl. Beyträge*, ii. pp. 48-54, pl. 3) a good description and fair figure of it, calling it the "Surinamische Sonnenreyger," *Ardea helias*, the first author to notice this form was Fermin, whose account of it, under the name of "Sonnenvogel," was published at Amsterdam in 1759 (*Descr.*, *&c.*, *de Surinam*, ii. p. 192), but was vague and meagre. In 1772, however, it was satisfactorily figured and described in Rozier's *Observations sur la Physique*, &c. (v. pt. 1, p. 212, pl. 1), as the *Petit Paon des roseaux*—by which name it was known in Cayenne.[6] A

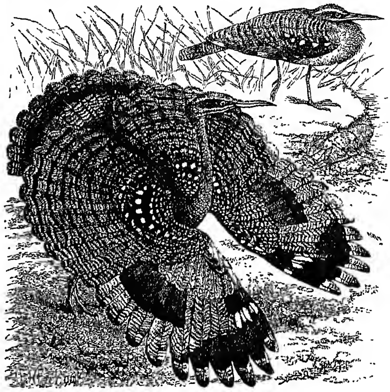

FIG. 1.—Sun-Bittern (*Eurypyga helias*).

few years later D'Aubenton figured it in his well-known series (*Pl. Enl.*, 782), and then in 1781 came Buffon (*H. N.*, *Oiseaux*, viii. pp. 169, 170, pl. xiv.), who, *calling* it "Le Caurâle ou petit Paon des roses," announced it as hitherto undescribed, and placed it among the Rails. In the same year appeared the above-cited paper by Pallas, who, notwithstanding his remote abode, was better informed as to its history than his great contemporary, whose ignorance, real or affected, of his fellow-countryman's priority in the field is inexplicable; and it must have been by inadvertence that, writing "roses" for "roseaux," Buffon turned the colonial name from one that had a good meaning into nonsense. In 1783 Boddaert, equally ignorant of what Pallas had done, called it *Scolopax solaris*,[7] and in referring it to that genus he was followed by Latham (*Synopsis*, iii. p. 156), by whom it was introduced to English readers as the "Caurale Snipe." Thus within a dozen years this bird was referred to three perfectly distinct genera, and in those days genera meant much more than they do now. Not until 1811 was it recognized as forming a genus of its own. This was done by Illiger, whose appellation *Eurypyga* has been generally accepted.

The Sun-Bittern is about as big as a small Curlew, but with much shorter legs and a rather slender, slightly decurved bill, blunt at the tip. The wings are moderate, broad, and rounded, the tail rather long and broad. The head is black with a white stripe over and another under each eye, the chin and throat being also white. The rest of the plumage is not to be described in a limited space otherwise than generally, being variegated with black, brown, chestnut, bay, buff, grey, and white—so mottled, speckled, and belted

[5] A name, says Buffon, intended to mean *Râle à queue*, that is, a tailed Rail.

[6] This figure and description were repeated in the later issue of this work in 1777 (i. pp. 679-681, pl. 1).

[7] Possibly he saw in the bird's variegated plumage a resemblance to the Painted Snipes, *Rhynchæa*. His specific name shows that he must have known how the Dutch in Surinam called it.

either in wave-like or zigzag forms as somewhat to resemble certain moths. The bay colour forms two conspicuous patches on each wing, and also an antepenultimate bar on the tail, behind which is a subterminal band of black. The irides are red; the bill is greenish olive; and the legs are pale yellow. As in the case of most South-American birds, very little is recorded of its habits in freedom, except that it frequents the muddy and wooded banks of rivers, feeding on small fishes and insects. In captivity it soon becomes tame, and has several times made its nest and reared its young (which, when hatched, are clothed with mottled down; *Proc. Zool. Society*, 1866, p. 76, pl. ix. fig. 1) in the Zoological Gardens (London), where examples are generally to be seen and their plaintive piping heard. It ordinarily walks with slow and precise steps, keeping its body in a horizontal position, but at times, when excited, it will go through a series of fantastic performances, spreading its broad wings and tail so as to display their beautiful markings. This species inhabits Guiana and the interior of Brazil; but in Colombia and Central America occurs a larger and somewhat differently coloured form which is known as *E. major*.

For a long while it seemed as if *Eurypyga* had no near ally, but, on the colonization of New Caledonia by the French, an extremely curious bird was found inhabiting most parts of that island, to which it is peculiar. This the natives called the Kagu, and it is

FIG. 2.—Kagu (*Rhinochetus jubatus*).

the *Rhinochetus jubatus* of ornithology. Its original describers, MM. Jules Verreaux and Des Murs, regarded it first as a Heron and then as a Crane (*Rev. et Mag. de Zoologie*, 1860, pp. 439-441, pl. 21; 1862, pp. 142-144); but, on Mr George Bennett sending two live examples to the Zoological Gardens, Mr Bartlett quickly detected in them an affinity to *Eurypyga* (*Proc. Zool. Society*, 1862, pp. 218, 219, pl. xxx.), and in due time anatomical investigation showed him to be right. The Kagu, however, would not strike the ordinary observer as having much outward resemblance to the Sun-Bittern, of which it has neither the figure nor posture. It is rather a long-legged bird, about as large as an ordinary Fowl, walking quickly and then standing almost motionless, with bright red bill and legs, large eyes, a full pendent crest, and is generally of a light slate-colour, paler beneath, and obscurely barred on its longer wing-coverts and tail with a darker shade. It is only when it spreads its wings that these are seen to be marked and spotted with white, rust-colour, and black, somewhat after the pattern of those of the Sun-Bittern. Like that bird too, the Kagu will, in moments of excitement, give up its ordinary placid behaviour and execute a variety of violent gesticulations, some of them even of a more extraordinary kind, for it will dance round, holding the tip of its tail or of one of its wings in a way that no other bird is known to do. Its habits in its own country were described at some length in 1863 by M. Jouan (*Mém. Soc. Sc. Nat. Cherbourg*, ix. pp. 97 and 235), and in 1870 by M. Marie (*Actes Soc. Linn. Bordeaux*, xxvii. pp. 323-326), the last of whom predicts the speedy extinction of this interesting form, a fate foreboded also by the statement of Messrs Layard (*Ibis*, 1882, pp. 534, 535) that it has nearly disappeared from the neighbourhood of the more settled and inhabited parts.

The internal and external structure of both these remarkable forms has been treated in much detail by Prof. Parker in the Zoological *Proceedings* (1864, pp. 70-72) and *Transactions* (vi. pp. 501-521, pls. 91, 92; x. pp. 307-310, pl. 54, figs. 7-9), as also by Dr Murie in the latter work (vii. pp. 465-492, pls. 56, 57), and the result of their researches shows that they, though separable as distinct Families, *Eurypygidæ* and *Rhinochetidæ*, belong to Prof. Huxley's *Geranomorphæ*, of which they must be deemed the relics of very ancient and generalized types. Their inter-relations to the *Rallidæ* (RAIL, vol. xx. p. 222), *Psophiidæ* (TRUMPETER, *q.v.*), and other groups there is not space here to consider, any more than there is to speculate on the bearings of their geographical position. It is only to be remarked that the eggs of both *Eurypyga* and *Rhinochetus* have a very strong Ralline appearance—stronger even than the figures published (*Proc. Zool. Society*, 1868, pl. xii.) would indicate. (A. N.)

SUNDA ISLANDS, the collective name of the whole series of islands in the East Indian Archipelago which extend from the peninsula of Malacca to New Guinea. They are divided into the Great Sunda Islands—*i.e.*, Sumatra, Java, Borneo, Celebes, Banca, and Billiton, with their adjacencies—and the Little Sunda Islands, of which the more important are Bali, Lombok, Sumbawa, Flores, Sandalwood Island, Adanara, Solor, Savu, Pantar, &c.

SUNDA STRAIT is the channel separating Sumatra from Java, and uniting the Indian Ocean with the Java Sea. It is 15 miles broad between the southmost point of Sumatra and the town of Anjer in Java. Right in the middle is the low-lying well-wooded island of Dwars in den Weg, otherwise Middle Island or Sungian. In 1883 Sunda Strait was the scene of the most terrific results of the eruption of Krakatoa, a volcano on the west side of the strait. The greater part of the island of Krakatoa was destroyed and two new islands, Steers Island and Calmeyer Island, were thrown up.

SUNDARBANS. See GANGES, vol. x. p. 68.

SUNDAY, or THE LORD'S DAY (ἡ τοῦ ἡλίου ἡμέρα, *dies Solis*; ἡ κυριακὴ ἡμέρα, *dies dominica, dies dominicus*[1]). According to all the four evangelists, the resurrection of our Lord took place on the first day of the week after His crucifixion (ἡ μία [τῶν] σαββάτων: Matt. xxviii. 1, Mark xvi. 2, Luke xxiv. 1, John xx. 1; πρώτη σαββάτου: Mark xvi. 9), and the Fourth Gospel describes a second appearance to His disciples as having occurred eight days afterwards (John xx. 26). Apart from this central fact of the Christian faith, the Pentecostal outpouring of the Spirit, seven weeks later, described in Acts ii., cannot have failed to give an additional sacredness to the day in the eyes of the earliest converts.[2] Whether the primitive church in Jerusalem had any special mode of observing it in its daily meetings held in the temple (Acts ii. 46) we cannot tell; but as there is no doubt that in these gatherings the recurrence of the Sabbath was marked by appropriate Jewish observances, so it is not improbable that the worship on the first day of the week had also some distinguishing feature. Afterwards, at all events, when Christianity had been carried to other places where from the nature of the case daily meetings for worship were impossible, the first day of the week was everywhere set apart for this purpose. Thus Acts xx. 7 shows that the disciples in Troas met weekly on the first day of the week for exhortation and the breaking of bread; 1 Cor. xvi. 2 implies at least some observance of the day; and the solemn commemorative character it had very early acquired is strikingly indicated by an incidental expression of the writer of the Apocalypse (i. 10), who for the first time gives it that name ("the Lord's day") by which it is almost invariably referred to by all writers of the century immediately succeeding apostolic

[1] The Teutonic and Scandinavian nations adopt the former designation (*Sunday, Sonntag, Söndag*, &c.), the Latin nations the latter (*Dimanche, Domenica, Domingo*, &c.).

[2] From an expression in the Epistle of Barnabas (c. 15), it would almost seem as if the ascension also was believed by some to have taken place on a Sunday.

times.[1] Among the indications of the nature and universality of its observance during this period may be mentioned the precept in the (recently discovered) *Teaching of the Apostles* (c. 14): "And on the Lord's day of the Lord (κατὰ κυριακὴν κυρίου) come together and break bread and give thanks after confessing your transgressions, that your sacrifice may be pure." Ignatius (*Ad Magn.*, c. 9) speaks of those whom he addresses as "no longer Sabbatizing, but living in the observance of the Lord's day (κατὰ κυριακὴν ζῶντες), on which also our life sprang up again."[2] Eusebius (*H. E.*, iv. 23) has preserved a letter of Dionysius of Corinth (175 A.D.) to Soter, bishop of Rome, in which he says: "To-day we have passed the Lord's holy day, in which we have read your epistle"; and the same historian (*H. E.*, iv. 26) mentions that Melito of Sardis (170 A.D.) had written a treatise on the Lord's day. Pliny's letter to Trajan in which he speaks of the meetings of the Christians "on a stated day" need only be alluded to. The first writer who mentions the name of Sunday as applicable to the Lord's day is Justin Martyr; this designation of the first day of the week, which is of heathen origin (see SABBATH, vol. xxi. p. 126), had come into general use in the Roman world shortly before Justin wrote. The passage is too well known to need quotation (*Apol.* i., 67) in which he describes how "on the day called Sunday" town and country Christians alike gathered together in one place for instruction and prayer and charitable offerings and the distribution of bread and wine; they thus meet together on that day, he says, because it is the first day in which God made the world, and because Jesus Christ on the same day rose from the dead.

As long as the Jewish Christian element continued to have any prominence or influence in the church, a tendency more or less strong to observe Sabbath as well as Sunday would of course persist. Eusebius (*H. E.*, iii. 27) mentions that the Ebionites continued to keep both days, and there is abundant evidence from Tertullian onwards that so far as public worship and abstention from fasting are concerned the practice was widely spread among the Gentile churches. Thus we learn from Socrates (*H. E.*, vi. c. 8) that in his time public worship was held in the churches of Constantinople on both days; the *Apostolic Canons* (can. 66 [65]) sternly prohibit fasting on Sunday or Saturday (except Holy Saturday); and the injunction of the *Apostolic Constitutions* (v. 20, cp. ii. 59, vii. 23) is to "hold your solemn assemblies and rejoice every Sabbath day (excepting one), and every Lord's day." In the primitive church the social conditions were such as hardly to admit of the question being raised, in Gentile circles at any rate, as to the manner in which either the Lord's day or the Sabbath ought further to be kept after the duty of congregational worship (usually early in the morning or late in the evening) had been discharged; but the whole matter was placed on an entirely new footing when the civil power, by the constitution of Constantine mentioned below, began to legislate as to the Sunday rest. The fourth commandment, holding as it does a conspicuous place in the decalogue, the precepts of which could not for the most part be regarded as of merely transitory obligation, had never of course escaped the attention of the fathers of the church; but, remembering the liberty given in the Pauline writings "in respect of a feast day or a new moon or a Sabbath" (Col. ii. 16, cf. Rom. xiv. 5, Gal. iv. 10, 11), they usually explained the "Sabbath day" of the commandment as meaning the new era that had been introduced by the advent of Christ, and interpreted the rest enjoined as meaning cessation from sin.[3] But, when a series of imperial decrees had enjoined with increasing stringency an abstinence from labour on Sunday, it was inevitable that the Christian conscience should be roused on the subject of the Sabbath rest also, and in many minds the tendency would be such as finds expression in the *Apostolic Constitutions* (viii. 33): "Let the slaves work five days; but on the Sabbath day and the Lord's day let them have leisure to go to church for instruction in piety." There is evidence of the same tendency in the opposite canon (29) of the council of Laodicea (363), which forbids Christians from Judaizing and resting on the Sabbath day, and actually enjoins them to work on that day, preferring the Lord's day and so far as possible resting as Christians. About this time accordingly we find traces of a disposition in Christian thinkers to try to distinguish between a temporary and a permanent element in the Sabbath day precept; thus Chrysostom (10th homily on Genesis) discerns the fundamental principle of that precept to be that we should dedicate one whole day in the circle of the week and set it apart for exercise in spiritual things. The view that the Christian Lord's day or Sunday is but the Christian Sabbath deliberately transferred from the seventh to the first day of the week does not indeed find categorical expression till a much later period, Alcuin being apparently the first to allege of the Jewish Sabbath that "ejus observationem mos Christianus ad diem dominicam competentius transtulit" (compare DECALOGUE, vol. vii. p. 17). But the subjoined sketch will incidentally show how soon and to how large an extent this idea has influenced the course of civil legislation on the subject.

Law relating to Sunday.

The earliest recognition of the observance of Sunday as a legal duty is a constitution of Constantine in 321 A.D., enacting that all courts of justice, inhabitants of towns, and workshops were to be at rest on Sunday (*venerabili die Solis*), with an exception in favour of those engaged in agricultural labour. This was the first of a long series of imperial constitutions, most of which are incorporated in the Code of Justinian, bk. iii. tit. 12 (*De Feriis*). The constitutions comprised in this title of the code begin with that of Constantine, and further provide that emancipation and manumission were the only legal proceedings permissible on the Lord's day (*die dominico*), though contracts and compromises might be made between the parties where no intervention of the court was necessary. Pleasure was forbidden as well as business. No spectacle was to be exhibited in a theatre or circus. If the emperor's birthday fell on a Sunday, its celebration was to be postponed. The seven days before and after Easter were to be kept as Sundays. In Cod. i. 4, 9, appears the humane regulation that prisoners were to be brought up for examination and interrogation on Sunday. On the other hand, Cod. iii. 12, 10, distinctly directs the torture of robbers and pirates, even on Easter Sunday, the divine pardon (says the law) being hoped for where the safety of society was thus assured. After the time of Justinian the observance of Sunday appears to have become stricter. In the West Charlemagne forbade labour of any kind. A century later in the Eastern empire No. liv. of the Leonine constitutions abolished the exemption of agricultural labour contained in the constitution of Constantine. It is worthy of notice that this exemption was specially preserved in England by a constitution of Archbishop Meopham. The canon law followed the lines of Roman law. The decrees of ecclesiastical councils on the subject have been very numerous. Much of the law is contained in the Decretals of Gregory, bk. ii. tit. 9 (*De Feriis*), c. 1 of which (translated) runs thus: "We decree that all Sundays be observed from vespers to vespers (*a vespera ad vesperam*), and that all unlaw-

[1] In the Epistle of Barnabas already referred to (c. 15) it is called "the eighth day": "We keep the eighth day with joyfulness, the day also in which Jesus rose again from the dead." Comp. Justin Martyr, *Dial. c. Tryph.*, c. 138.

[2] The longer recension runs: "But let every one of you keep the Sabbath after a spiritual manner. . . . And after the observance of the Sabbath let every friend of Christ keep the Lord's day as a festival, the resurrection day, the queen and chief of all the days." The writer finds a reference to the Lord's day in the titles to Pss. vi. and xii., which are "set to the eighth."

[3] See Ignat., *Ad Magn.*, *ut supra*, and Ep. of Barnabas (c. 15): "Your present Sabbaths are not acceptable unto me, but that is which I have made when, giving rest to all things, I shall make a beginning of the eighth day." So practically Tertullian (*Resp. ad Jud.*, c. 4) and Clement of Alexandria. According to Augustine also (*De Sp. et Lit.*, 14), the observance of the Sabbath is to be taken in a spiritual sense.

ful work be abstained from, so that in them trading or legal proceedings be not carried on, or any one condemned to death or punishment, or any oaths be administered, except for peace or other necessary reason." Works of necessity (especially in the case of perishable materials or where time was important, as in fishing) were allowed, on condition that a due proportion of the gain made by work so done was given to the church and the poor. The consent of parties was insufficient to give jurisdiction to a court of law to proceed on Sunday, though it was sufficient in the case of a day sanctified by the ecclesiastical authority for a temporary purpose, *e.g.*, a thanksgiving for vintage or harvest.

In England legislation on the subject began early and continues down to the most modern times. As early as the 7th century the laws of Ina, king of the West Saxons, provided that, if a "theowman" worked on Sunday by his lord's command, he was to be free and the lord to be fined 30s.; if a freeman worked without his lord's command, the penalty was forfeiture of freedom or a fine of 60s., and twice as much in the case of a priest. The laws of Æthelstan forbade marketing, of Æthelred folkmoots and hunting, on the Sunday. In almost all the pre-Conquest compilations there are admonitions to keep the day holy. The first allusion to Sunday in statute law proper is the Act of 28 Edw. III. c. 14 (now repealed), forbidding the sale of wool at the staple on Sunday. The mass of legislation from that date downwards may be divided, if not with strict accuracy, at least for purposes of convenience, into five classes,—ecclesiastical, constitutional, judicial, social, and commercial. The following sketch of the legislation can scarcely presume to be exhaustive, but it will probably be found not to omit any statute of importance. It should be noticed that the terms "Sunday" and "Lord's day" are used in statutes. The term "Sabbath" occurs only in ordinances of the Long Parliament. "Sabbath breaking" is sometimes used as a popular expression for a violation of the Acts for Sunday observance, but it is objected to by Blackstone as being legally incorrect. Good Friday and Christmas Day are as a rule in the same legal position as Sunday. In English law Sunday is reckoned from midnight to midnight, not as in canon law *a vespera ad vesperam*. The Acts mentioned below are still law unless repeal of any of them is specially mentioned.

Ecclesiastical.—Before the Reformation there appears to be little or no statutory recognition of Sunday, except as a day on which trade was interdicted or national sports directed to be held. Thus the repealed Acts 12 Ric. II. c. 6 and 11 Hen. IV. c. 4 enjoined the practice of archery on Sunday. The church itself by provincial constitutions and other means declared the sanctity of the day, and was strong enough to visit with its own censures those who failed to observe Sunday. With the Reformation, however, it became necessary to enforce the observance of Sunday by the state in face of the question mooted at the time as to the divine or merely human institution of the day as a holy day. Sunday observance was directed by injunctions of both Edward VI. and Elizabeth, as well as by Acts of Parliament in their reigns. 5 and 6 Edw. VI. c. 1 (the second Act of Uniformity) enacted that all inhabitants of the realm were to endeavour themselves to resort to their parish church or chapel accustomed, or upon reasonable let thereof to some usual place where common prayer is used every Sunday, upon pain of punishment by the censures of the church. This is still law except as to Dissenters (see 9 and 10 Vict. c. 59). The same principle was re-enacted in the Act of Uniformity of Elizabeth (1 Eliz. c. 2), with the addition of a temporal punishment, viz., a fine of twelve pence for each offence. This section of the Act is, however, no longer law, and it appears that the only penalty now incurred by non-attendance at church is the shadowy one of ecclesiastical censure. 5 and 6 Edw. VI. c. 3 directed the keeping of all Sundays as holy days, with an exception in favour of husbandmen, labourers, fishermen, and other persons in harvest or other time of necessity. At the end of the reign of Elizabeth canon 13 of the canons of 1603 (which are certainly binding upon the clergy, and probably upon the laity as far as they are not contrary to the law, statutes, and customs of the realm, or the royal prerogative) provided that "all manner of persons within the Church of England shall celebrate and keep the Lord's day, commonly called Sunday, according to God's holy will and pleasure and the orders of the Church of England prescribed in that behalf, that is, in hearing the word of God read and taught, in private and public prayers, in acknowledging their offences to God and amendment of the same, in reconciling themselves charitably to their neighbours where displeasure hath been, in oftentimes receiving the communion of the body and blood of Christ, in visiting the poor and sick, using all godly and sober conversation." The Long Parliament, as might be expected, occupied itself with the Sunday question. An ordinance of 1644, c. 51, directed the Lord's day to be celebrated as holy, as being the Christian Sabbath. Ordinances of 1650, c. 9, and 1656, c. 15, contained various minute descriptions of crimes against the sanctity of the Lord's day, including travelling and "vainly and profanely walking." The Act of Uniformity of Charles II. (13 and 14 Car. II. c. 4) enforced the reading on every Lord's day of the morning and evening prayer according to the form in the Book of Common Prayer,—a duty which had been previously enjoined by canon 14. By the first of the Church Building Acts (58 Geo. III. c. 45, s. 65) the bishop may direct a third service, morning or evening, where necessary, in any church built under the Act. By 1 and 2 Vict. c. 106, s. 80, he may order the performance of two full services, each if he so direct to include a sermon. The Burial Laws Amendment Act, 1880, forbids any burial under the Act taking place on Sunday.

Constitutional.—Parliament has occasionally sat on Sunday in cases of great emergency, as on the demise of the crown. In one or two cases in recent years divisions in the House of Commons have taken place early on Sunday morning. The Ballot Act, 1872, enacts that in reckoning time for election proceedings Sundays are to be excluded. A similar provision is contained in the Municipal Corporations Act, 1882, as to proceedings under that Act.

Judicial.—As a general rule Sunday for the purpose of judicial proceedings is a *dies non*. Legal process cannot be served or executed on Sunday, except in cases of treason, felony, or breach of the peace (29 Car. II. c. 7, s. 6). Proceedings which do not need the intervention of the court are good, *e.g.*, service of a citation or notice to quit or claim to vote. By 11 and 12 Vict. c. 42, s. 4, a justice may issue a warrant of apprehension or a search warrant on Sunday. The Rules of the Supreme Court, 1883, provide that the offices of the Supreme Court shall be closed on Sundays, that Sunday is not to be reckoned in the computation of any limited time less than six days allowed for doing any act or taking any proceeding, and that, where the time for doing any act or taking any proceeding expires on Sunday, such act or proceeding is good if done or taken on the next day. By the County Court Rules, 1886, the only county court process which can be executed on Sunday is a warrant of arrest in an Admiralty action.

Social.—Under this head may be grouped the enactments having for their object the regulation of Sunday travelling and amusements. The earliest example of non-ecclesiastical interference with recreation appears to be the *Book of Sports* issued by James I. in 1618. Royal authority was given to all but recusants to exercise themselves after evening service in dancing, archery, leaping, vaulting, May-games, Whitsun-ales, morris-dances, and setting up of Maypoles; but bear and bull baiting, interludes, and bowling by the meaner sort were prohibited. In 1625 the first Act of the reign of Charles I. (1 Car. I. c. 1), following the lines of the *Book of Sports*, inhibited meetings, assemblies, or concourse of people out of their own parishes on the Lord's day for any sports and pastimes whatsoever, and any bear-baiting, bull-baiting, interludes, common plays, or other unlawful exercises and pastimes used by any person or persons within their own parishes, under a penalty of 3s. 4d. for every offence. The Act, it will be noticed, impliedly allows sports other than the excepted ones as long as only parishioners take part in them. An Act which has had more important consequences in recent years is 21 Geo. III. c. 49 (drawn by Dr Porteus, bishop of London). It enacts that any place opened or used for public entertainment and amusement or for public debate upon any part of the Lord's day called Sunday, to which persons are admitted by payment of money or by tickets sold for money, is to be deemed a disorderly house. The keeper is to forfeit £200 for every day on which it is opened or used as aforesaid on the Lord's day, the manager or master of the ceremonies £100, and every doorkeeper or servant £50. The advertising or publishing any advertisement of such an entertainment is made subject to a penalty of £50. It has been held that a meeting the object of which was not pecuniary gain (though there was a charge for admission), but an honest intention to introduce religious worship, though not according to any established or usual form, was not within the Act. On this principle forms of worship most directly opposed to the prevailing feeling of the country, such as Mormonism or Mohammedanism, are protected. In 1875 actions were brought in the Courts of Queen's Bench and Exchequer against the Brighton Aquarium Company, and penalties recovered under the Act. The penalties were remitted by the crown; but, as doubts were felt as to the power of the crown to remit in such a case, 38 and 39 Vict. c. 80 was passed to remove such doubts and to enable the sovereign to remit in whole or in part penalties recovered for offences against the Act of Geo. III. The rules made by justices and the bye-laws made by local authorities for the government of theatres and places of public entertainment usually provide for closing on Sunday. The Sunday opening of museums and art galleries is governed by local regulations; there is no general law on the subject, though attempts have been made in that direction. The House of Lords recently passed a resolution in favour of the principle. A public billiard table must not be used on Sunday (8 and 9 Vict. c. 109). The Game Act (1 and 2 Will. IV. c. 32, s. 3) makes it punishable with a fine of £5 to kill game or use a dog or net for sporting purposes on Sunday. Provisions for the regulation of street traffic on Sundays during divine service in the metropolis and provincial towns may be made by the local authorities under the powers of the Metropolis Management Acts, the Town Police Clauses Act, and the Public Health Act. Hackney carriages may ply for hire in London (1 and 2 Will. IV. c. 22). Where a railway company

runs trains on Sunday one cheap train each way is to be provided (7 and 8 Vict c 85, s 10) Most of the railway companies' own Acts also provide for the running of Sunday trains

Commercial —At common law a contract made on Sunday is not void, nor is Sunday trading or labour unlawful At an early period, however, the legislature began to impose restrictions, at first by making Sunday trade impossible by closing the places of ordinary business, later by declaring certain kinds of trade and labour illegal, still later by attempting to prohibit all trade and labour 28 Edw III c 14 (referred to above) closed the wool market on Sunday 27 Hen VI c 5 (the earliest Sunday Act still in force) prohibited fairs and markets on Sunday (necessary victual only excepted), unless on the four Sundays in harvest,—an exemption since repealed by 13 and 14 Vict c 23 4 Edw IV c 7 (now repealed) restrained the shoemakers of London from carrying on their business on Sunday 3 Car I c 1 inflicted a penalty of 20s on any carrier or drover travelling on the Lord's day, and a penalty of 6s 8d on any butcher killing or selling on that day Both this and the previous Act of 1625 were originally passed only for a limited period, but by subsequent legislation they have become perpetual Next in order is the most comprehensive Act on the subject, 29 Car II c 7, "An Act for the better observance of the Lord's day, commonly called Sunday" After an exhortation to the observation of the Lord's day by exercises in the duties of piety and true religion, publicly and privately, the Act provides as follows —No tradesman, artificer, workman, labourer, or other person whatsoever shall do or exercise any worldly labour, business, or work of their ordinary callings upon the Lord's day or any part thereof (works of necessity and charity only excepted), and every person being of the age of fourteen years or upwards offending in the premises shall for every such offence forfeit the sum of 5s , and no person or persons whatsoever shall publicly cry, show forth, or expose to sale any wares, merchandises, fruit, herbs, goods, or chattels whatsoever upon the Lord's day or any part thereof upon pain that every person so offending shall forfeit the same goods so cried, or showed forth, or exposed to sale (s 1) No drover, horse courser, waggoner, butcher, higgler, their or any of their servants, shall travel or come into his or their lodging upon the Lord's day or any part thereof, upon pain that each and every such offender shall forfeit 20s for every such offence, and no person or persons shall use, employ, or travel upon the Lord's day with any boat, wherry, lighter, or barge, except it be upon extraordinary occasion to be allowed by some justice of the peace, &c , upon pain that every person so offending shall forfeit and lose the sum of 5s for every such offence In default of distress or non payment of forfeiture or penalty the offender may be set publicly in the stocks for two hours (s 2) Nothing in the Act is to extend to the prohibiting of dressing of meat in families, or dressing or selling of meat in inns, cooks' shops, or victualling houses for such as cannot be otherwise provided, nor to the crying or selling of milk before nine in the morning or after four in the afternoon (s 3) Prosecutions must be within ten days after the offence (s 4) The hundred is not responsible for robbery of persons travelling upon the Lord's day (s 5) Service of process on the Lord's day is void , see above (s 6) This Act has frequently received judicial construction The use of the word "ordinary" in section 1 has led to the establishment by a series of decisions of the principle that work done out of the course of the ordinary calling of the person doing it is not within the Act Thus the sale of a horse on Sunday by a horse-dealer would not be enforcible by him and he would be liable to the penalty, but these results would not follow in the case of a sale by a person not a horse dealer Certain acts were held to fall within the exception as to works of necessity and charity, *e g*, baking provisions for customers, running stage-coaches, hiring farm-labourers The legislature also intervened to obviate some of the inconveniences caused by the Act By 10 and 11 Will III c 24 mackerel was allowed to be sold before and after service By 11 and 12 Will III c 21 forty watermen were allowed to ply on the Thames on Sunday By 9 Anne c 23 licensed coachmen or chairmen might be hired on Sunday By 34 Geo III bakers were allowed to bake and sell bread at certain hours These Acts are all repealed Still law are 2 Geo III c 15 s 7, allowing fish carriages to travel on Sunday in London and Westminster , 7 and 8 Geo IV c 75, repealing section 2 of the Act of Charles II as far as regards Thames boatmen , and 6 and 7 Will IV c 37, permitting bakers out of London to carry on their trade up to 1 30 P M The penalty of the stocks denounced by sect 2 is practically obsolete (see STOCKS) The prosecution of offences under the Act of Charles II is now subject to 34 and 35 Vict c 87 (an Act which was passed for a year, but has since been annually continued by the Expiring Laws Continuance Act of each session), by which no prosecution or proceeding for penalties under that Act can be instituted except with the consent in writing of the chief officer of a police district or the consent of two justices or a stipendiary magistrate This is surely a more reasonable means of providing against any hardship caused by the Act than the *ex post facto* power of remission of penalties incurred under 21 Geo III c 49 Besides the general Act of Charles II , there are various Acts dealing with special trades , of these the Licensing Acts and the Factory and Workshop Act are the most important By the Licensing Act, 1874, premises licensed for the sale of intoxicating liquors by retail are to be open on Sunday only at certain hours, varying according as the premises are situate in the metropolitan district, a town or populous place, or elsewhere An exception is made in favour of a person lodging in the house or a *bona fide* traveller, who may be served with refreshment during prohibited hours, unless in a house with a six day licence Attempts have often been made, but hitherto without success, to induce the legislature to adopt the principle of complete Sunday closing in England as a whole, or in particular counties [1] In the session of 1886 a Bill for Sunday closing in Durham was passed by the Commons, but rejected by the Lords The advocates of Sunday closing in Ireland and Wales have been more successful The Sale of Liquors on Sunday (Ireland) Act, 1878, prohibits the opening of licensed premises on Sunday, except in Dublin, Cork, Limerick, Waterford, and Belfast In these towns such premises may be opened from 2 P M to 7 P M Exemptions are also made in favour of lodgers and travellers, of packet boats and railway stations The Sunday Closing (Wales) Act, 1881, contains no exceptions of towns, like the Irish Act, and the only exemption is the sale of intoxicating liquors at railway stations The Factory and Workshop Act, 1878, forbids the employment of a child, young person, or woman on Sunday in a factory or workshop But a young person or woman of the Jewish religion may be employed on Sunday by a Jewish manufacturer, provided that the factory or workshop be not open for traffic on Sunday There are a few other legislative provisions of less importance which may be noticed Fishing for salmon on Sunday by any means other than a rod and line is an offence under the Salmon Fishery Act, 1861 By the same Act a free passage for the salmon through all cribs, &c , used for fishery is to be left during the whole of Sunday Carrying on the business of a pawnbroker on Sunday is an offence within the Pawnbrokers Act, 1872 Distilling and rectifying spirits on Sunday is forbidden by the Spirits Act, 1880 The effect of Sunday upon bills of exchange is declared by the Bills of Exchange Act, 1882 A bill is not invalid by reason only of its bearing date on a Sunday (s 13) Where the last day of grace falls on a Sunday, the bill is payable on the preceding business day (s 14) Sunday is a "non-business day" for the purposes of the Act (s 92) This review of Sunday legislation pretty clearly shows that its tendency at present is opposed to extending facilities to trade on Sunday, but that as to recreation the tendency is rather in the other direction [2]

Scotland —The two earliest Acts dealing with Sunday are somewhat out of harmony with the general legislation on the subject 1457, c 6, ordered the practice of archery on Sunday , 1526, c 8, allowed markets for the sale of flesh to be held on Sunday at Edinburgh Then came a long series of Acts forbidding the profanation of the day, especially by salmon fishing, holding fairs and markets, and working in mills and salt pans 1579, c 70, and 1661, c 18, prohibited all work and trading on the Sabbath The later legislation introduced an exception in favour of duties of necessity and mercy, in accordance with ch 21 of the Confession of Faith In more modern times the exigencies of travelling have led to a still further extension of the exception The Sabbath Observance Acts were frequently confirmed, the last time in 1696 These Acts were held by the High Court of Justiciary in 1870 to be still subsisting, as far as they declare the keeping open shop on Sunday to be an offence by the law of Scotland (Bute's Case, 1 Couper's *Reports*, 495) The forms of certificate in the schedule to the Public Houses Acts Amendment Act, 1862 (superseding those in the Forbes Mackenzie Act of 1853), provide for the closing on Sunday of public houses and of premises licensed for the sale of exciseable liquors, and of inns and hotels, except for the accommodation of lodgers and travellers Scots law is stricter than English in the matter of Sunday fishing By 55 Geo III c 94 the setting or hauling of a herring-net on Sunday renders the net liable to forfeiture By the Salmon Fisheries (Scotland) Act, 1862, fishing for salmon on Sunday, even with a rod and line, is an offence As to contracts and legal process, the law is in general accordance with that of England Contracts are not void, apart from statute, simply because they are made on Sunday Diligence cannot be executed, but a warrant of imprisonment or *meditatio fugæ* is exercisable It should be noticed that, contrary to the English custom, the term "Sabbath" was generally used in the legislation of the Scottish parliament.

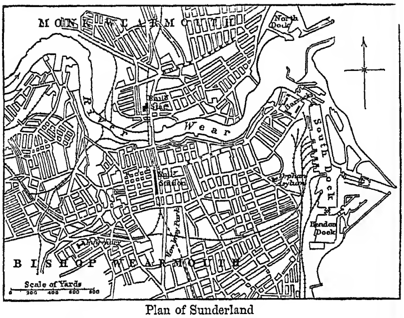
United States —Some of the early colonial ordinances enforced the obligation of attendance at church, as in England In most States there is legislation on the subject of Sunday, following, as a general rule, the lines of the English Act of Charles II In

1 The Act 1 James I c 9 (now repealed) appears, however, to have provided for closing ale houses in most cases, except on usual working days

2 See, in addition to the authorities cited, Lyndewode, *Provincial Constitutions* bk ii chap iii , Ayliffe, *Parergon*, p 470 , Gibson, *Codex*, tit x chap i , Heylin, *History of the Sabbath*, part ii the article "Lord's Day" (by Bishop Barry) in the *Dictionary of Christian Antiquities* , and Hessey, *Sunday*, (Bampton Lectures, 1860) , also Robert Cox's works on the Sabbath

Massachusetts travelling, except from necessity or charity, is punishable with a fine of ten dollars. Provision is sometimes made, as in the Massachusetts laws, for the benefit of persons observing Saturday as the Sabbath, on condition that they disturb no other person. The number of Sunday trains is often limited by State legislation. In some of the New England States Sunday is from sunset to sunset. In most States, however, it is reckoned, as in England, from midnight to midnight. By the constitution of the United States, art. I. s. 7, Sundays are to be excluded from the ten days allowed the president to return a Bill. A similar provision is often contained in State constitutions as to the return of a Bill by the governor. The United States legislation on the subject of Sunday is not important. It directs that naval and military studies are not to be pursued, and that the day is not to be reckoned in bankruptcy proceedings. (J. W†.)

SUNDERLAND, a municipal and parliamentary borough, market town, and large seaport of Durham, England, is situated at the mouth of the river Wear and on the North-Eastern Railway, 12 miles south-east of Newcastle-on-Tyne and 77 north-north-west of York. The municipal borough includes, besides the township of Sunderland proper on the south bank of the river, the adjoining township of Bishopwearmouth, which embraces about three-fifths of the total inhabitants, and the township of Monkwearmouth, on the north bank of the river. Sunderland proper consists chiefly of the High Street and other streets near the docks. It is connected with Monkwearmouth by a cast-iron bridge, designed by Rowland Burdon, and consisting of one arch with a span of 236 feet and a height above low water of 100 feet. It was opened in 1796 and widened in 1858. The only ecclesiastical building of antiquarian interest is



Plan of Sunderland.

St Peter's church, Monkwearmouth, which still retains the tower with other portions of the ancient Saxon building attached to the monastery founded by Benedict Biscop in 674. The modern public buildings embrace the custom-house (1837), the Sunderland and North Durham Liberal club in the Ionic style (1839), the corporation offices, the workmen's hall, the new general market, the Victoria hall (1871), the assembly hall, and two theatres. The charitable and benevolent institutions are numerous, including Gibson's almshouses (1725) for twelve poor persons, Bowe almshouses (1725), Trinity Church almshouses (1719, rebuilt in 1876) for eight aged poor, the marine almshouses (1820), the eye infirmary (1836), the sailors' home (1856), the orphan asylum (1853), the infirmary and dispensary (erected in 1868 and extended in 1882), and the blind institute, for which a new building has recently been erected. For the literary society and subscription library, originally founded in 1793, a new building was erected in 1877. The people's park at Bishopwearmouth, 17 acres in extent, contains a bronze statue of Sir Henry Havelock, who was born at Ford Hall in the neighbourhood. The park was lately increased by an addition of 10 acres, called the Extension Park, in which there is a statue of Alderman Candlish, and a free library, museum, art gallery, and winter garden. Roker, on the north side of Sunderland, is a favourite bathing-place. The population of the municipal borough (area, 3306 acres) in 1871 was 98,242, and in 1881 it was 116,542 (males 57,131, females 59,411). The population of the parliamentary borough (area, 5130 acres) in the same years was 104,409 and 124,841 respectively.

Much of the prosperity of Sunderland is due to the coal and limestone in the neighbourhood of the river Wear, of which it is the port. Its export of coal began in the reign of Henry VII., the trade being principally with London and the western coasts of England, although large quantities were also shipped to Holland, France, and other parts of the Continent. The coal trade is still of great importance, and the Monkwearmouth colliery is one of the deepest coal-pits in the world,—381 fathoms. Sunderland vies with the Clyde for its iron shipbuilding. The number of iron ships built in 1885 was 31 with a tonnage of 30,520 for home and 2 with a tonnage of 1255 for foreigners; of steel ships, 9 with a tonnage of 8099 for home and 3 with a tonnage of 3635 for foreigners. Along both banks of the Wear numerous extensive works of various kinds are situated, including anchor and chain cable works, glass and bottle works, roperies, forges, iron-works, chemical works, paper-mills, breweries, and lime-kilns. The modern prosperity of the town has been largely promoted by the enterprise of George Hudson, the "railway king." The conservation of the port is vested in the Wear commissioners, to whose care the South Dock was transferred by the Wear Navigation and Sunderland Dock Act of 1859. Under their auspices great extensions and improvements have been made, and there are now three large deep water docks, embracing a total area of 43 acres, viz., Hudson dock north (18), Hudson dock south (14), and Hendon dock (11). Monkwearmouth dock, 6 acres in extent and the property of the railway company, is chiefly used for the export of coal. New piers over half a mile in length are now (1887) being erected. The average annual value of the imports of foreign and colonial merchandise for the five years ending 1886 was a little over £700,000, and of the exports of produce of the United Kingdom a little over £600,000. The coasting trade, in regard to which specific details are wanting, is, however, more important. The total number of British and foreign vessels, sailing and steam, that entered the port of Sunderland with cargoes or in ballast from foreign countries, British possessions, and coastwise in 1876 was 9708 of 2,329,576 tons and in 1885 9451 of 2,764,174 tons. The numbers that cleared in the same years were respectively 9430 of 2,357,430 tons and 9419 of 2,824,218 tons.

The early history of the borough is associated with Monkwearmouth, which existed long before the town on the other side of the river, and had its origin in a convent which was founded by St Bega in the 7th century and converted into a monastery for Benedictines by Biscop in 674. Bede was born at Wearmouth in 673, and in his seventh year was placed under the charge of Biscop. The monastery was reconstituted as a cell of Durham in 1084. About the close of the 12th century the inhabitants of Sunderland received from Bishop Pudsey a charter of free customs and privileges similar to those of Newcastle-on-Tyne. In 1634 the town was incorporated under the title of "mayor, aldermen, and commonalty," with the privilege of holding a market and annual fairs. In the preamble of the charter it is stated to have been a borough from time immemorial under the name of New Monkwearmouth, and to have been in the enjoyment of various liberties and free customs conferred by the bishops of Durham. Under a special Act in 1851 the town council was constituted the urban sanitary authority. Extensive drainage works have been carried out, as well as important street improvements. Sunderland has returned two members to the House of Commons since 1832. A large number of Scotch families settled in the town in 1640 and gave a considerable impulse to its trade. During the Civil War the inhabitants embraced the cause of the Parliament, while the neighbouring Newcastle held out for the king for two years. The Scottish army under Leslie, earl of Leven, entered Sunderland on 4th March 1644, and the king's forces followed them; but no engagement took place beyond desultory firing.

SUNDERLAND, ROBERT SPENCER, SECOND EARL OF (1640-1702), was the eldest son of Henry, the first earl, and Lady Dorothy Sidney, eldest daughter of Robert, second earl of Leicester. He was born in 1640 and succeeded his father (who was killed at Newbury) in the title on 20th September 1643. During the years 1671-73 he acted as ambassador at Madrid, Paris, and Cologne consecutively, and in 1678 went to Paris as ambassador

extraordinary. It was during this period of his life that he acquired that suppleness of feeling and love of finesse which may be traced throughout his subsequent career. From February 1679 to January 1681, a period when the country was rent in twain by real or fancied dangers to the Protestant faith, he held the post of secretary of state for the northern department, but his conduct in office was not marked by discretion. He voted for the exclusion of the duke of York from the succession to the throne, and the ill-feeling which this action created in the mind of Charles II. was augmented by the overtures which Sunderland made to the prince of Orange, whilst differences of opinion on the subject of the Exclusion Bill brought about a fierce quarrel between Sunderland and Halifax, the head of the "trimmers." Early in 1683, having been reconciled to the duke of York and having secured a warm friend in the duchess of Portsmouth, Sunderland regained his place as secretary for the northern department. When James II. succeeded to the throne, Sunderland became secretary for the southern department, from March 1685 to 27th October 1688, for most of which period he held the additional post of president of the council, and was a member of the high commission for ecclesiastical causes. He afterwards claimed that he had used his influence to mitigate the proceedings of this obnoxious body, but he went sufficiently far with his royal master to sign the warrant for the committal of the bishops and to appear as a witness against them. Though Lord Sunderland was in sympathy, if not in actual communion, with Roman Catholicism, he hesitated to commit himself entirely to the acts of the fierce devotees who surrounded James II., and through their opposition he was dismissed in disgrace and sought security in Holland. He had been too much engaged in the acts of James II. to find a place among the advisers of William and Mary.

The visit which William paid to Althorp in Northamptonshire, the country seat of Sunderland, in 1695 was the prelude of a reconciliation between the king and his ambitious subject and of Sunderland's recall into public affairs. From April to December 1697 he discharged the duties of lord chamberlain of the household and for the greater part of that time he was also lord justice of England, but he finally retired from active life in the close of 1697 through disgust at the check which William received in the retention of a standing army. The rest of his life was passed in strict seclusion at Althorp, and there he died on 28th September 1702.

Lord Sunderland possessed a keen intellect and was consumed by intense restlessness, but his character was wanting in steadfastness, and he yielded too easily to opposition. His adroitness in intrigue and his fascinating manners were exceptional even in an age when such qualities formed part of every statesman's education, but the characteristics which ensured him success in the House of Lords and in the royal closet led to failure in his attempts to understand the feelings of the mass of his countrymen. Consistency of conduct was not among the objects which he aimed at, nor did he shrink from thwarting in secret a policy which he supported in public. A large share of the discredit attaching to the measures of James II. must be assigned to the earl of Sunderland.

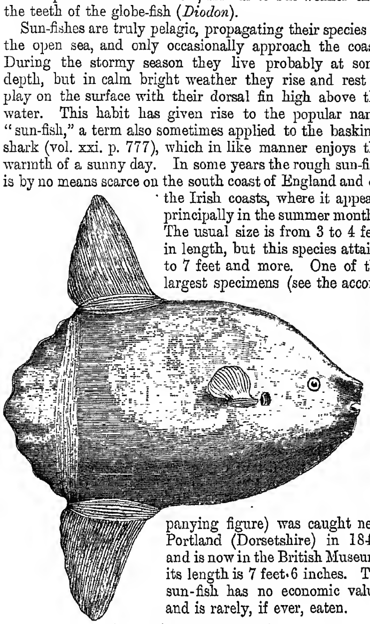
SUNDERLAND, CHARLES SPENCER, THIRD EARL OF (1675-1722), was the second son of the second earl, but on the death of his elder brother at Paris, on 5th September 1688, he became the heir to the peerage. He was born in 1675, and when twenty years old was sent to the House of Commons by the two constituencies of Hedon in Yorkshire and Tiverton in Devonshire. He chose the latter, and represented it until his succession to the earldom of Sunderland in 1702. Throughout this period of his life his career was undistinguished; his first start in the world of politics occurred in 1705, when he was sent to Vienna as envoy extraordinary, a mission which he discharged with signal ability. Although Sunderland was tinged with republican feeling and had rendered himself personally obnoxious to Anne, he was foisted by the all-powerful influence of his father-in-law, the duke of Marlborough, into the ministry as secretary of state for the southern department. This office he held from 3d December 1706 to 14th June 1710, when he fell, as he rose, through his connexion with the duke and duchess of Marlborough. The queen offered him a pension of £3000 a year, but he proudly refused the temptation, saying that, if he could not serve, he would not plunder, his country. After the accession of George I. he was lord lieutenant of Ireland (1714-15), lord keeper of the privy seal (1715-17), and secretary of state for the northern department (April 1717 to March 1718). At the latter date he was raised to the post of prime minister, holding with the office of first lord of the treasury the position of lord president of the council. Sir Robert Walpole had been shelved, and he revenged himself on the new administration by resisting and defeating the Bill which was designed to limit the numbers of the House of Lords,—a victory over Sunderland which led to a partial reconciliation between him and Townshend and Walpole, his rivals. Lord Sunderland was at the head of affairs during the South Sea mania, and the bursting of the financial bubble led to his political ruin. Through Walpole's influence he was acquitted of personal corruption, but he was forced to resign his place as first lord of the treasury on 1st April 1721. The passion for intrigue which characterized the father had descended to the son; he was ever plotting, and within a few months after Walpole had saved him from disgrace, if not from a worse fate, he was engaged in scheming against the friend who had saved him. But his plots were interrupted by his death, which occurred on 19th April 1722. Lord Sunderland's manners were repelling and his disposition was harsh, but he stands high among his compeers for disinterestedness. The love of books ranked among the ruling passions of his life, and he spent his leisure hours and his wealth in forming the great collection at Althorp.

SUN-FISH. This name is chiefly and properly applied to a marine fish (*Orthagoriscus*) which by its large size, grotesque appearance, and numerous peculiarities of organization has attracted the attention equally of fishermen as of naturalists. Only two species are known,—the rough or short sun-fish (*O. mola*), which is found in all seas of the temperate and tropical zones, and the much smaller and scarcer smooth or oblong sun-fish (*O. truncatus*), of which only a small number of specimens have been obtained from the Atlantic and Indian Oceans. That this genus belongs to the order *Plectognathi* and is allied more especially to the globe-fishes (*Diodon* and *Tetrodon*) has been indicated in the article ICHTHYOLOGY (vol. ix. pp. 663, 694), where also the principal anatomical peculiarities have been noticed, and where illustrations of the young have been given (see figs. 64, 65).

Sun-fishes have the appearance of tailless fish. This is due to the extreme shortening of the tail, which is supported by only a few short vertebræ and reduced to a broad fringe of the trunk. Directly in front of it rise dorsal and anal fins, high and broad, similar to each other in size and triangular in form. The head is completely merged in the trunk, the boundary between them being indicated only by a very small and narrow gill-opening and a comparatively small pectoral fin. This fin can be of but little use in locomotion, and the horizontal and vertical movements of the fish, as well as the maintenance of its body in a vertical position, are evidently executed by

the powerful dorsal and anal fins. The small mouth, situated in front of the head, is armed with an undivided dental plate above and below, similar to but weaker than the teeth of the globe-fish (*Diodon*).

Sun-fishes are truly pelagic, propagating their species in the open sea, and only occasionally approach the coast. During the stormy season they live probably at some depth, but in calm bright weather they rise and rest or play on the surface with their dorsal fin high above the water. This habit has given rise to the popular name "sun-fish," a term also sometimes applied to the basking-shark (vol. xxi. p. 777), which in like manner enjoys the warmth of a sunny day. In some years the rough sun-fish is by no means scarce on the south coast of England and on the Irish coasts, where it appears principally in the summer months. The usual size is from 3 to 4 feet in length, but this species attains to 7 feet and more. One of the largest specimens (see the accompanying figure) was caught near Portland (Dorsetshire) in 1846, and is now in the British Museum; its length is 7 feet 6 inches. The sun-fish has no economic value, and is rarely, if ever, eaten.



Sun-fish (*Orthagoriscus mola*).

Whilst the rough sun-fish has a granulated, rough, shagreen-like skin, the second species (*O. truncatus*) has the surface of the body smooth and polished, with its small dermal scutes arranged in a tesselated fashion. It is oblong in shape, the body being much longer than it is deep. The sides are finely ornamented with transverse silvery, black-edged stripes running downwards to the lower part of the abdomen. It has not been found to exceed 2 feet in length, but is very scarce, only a few specimens having been captured on the coasts of Europe, at the Cape of Good Hope, and off Mauritius.

SUNFLOWER. In the modern vernacular this name is most commonly applied to various species of *Helianthus*, especially to *H. annuus*; but, as this is a tropical American herb, and the word "sunflower" or something corresponding to it existed in English literature prior to its introduction, or at any rate prior to its general diffusion in gardens, it is obvious that some other flower than the *Helianthus* must have been intended. The marigold (*Calendula officinalis*) is considered by Dr Prior to have been the plant intended by Ovid (*Met.*, iv. 269-70)—

> ". . . Illa suum, quamvis radice tenetur,
> Vertitur ad solem; mutataque servat amorem"—

and likewise the *solsæce* of the Anglo-Saxon, a word equivalent to *solsequium* (sun-following). But this movement with the sun is more imaginary than real, the better explanation being afforded by the resemblance to "the radiant beams of the sun," as Gerard expresses it. The central disk of tubular hermaphrodite flowers, encompassed by the spreading neuter florets of the ray, has, indeed, a marked resemblance to the sun as conventionally depicted. The florets are provided with two or three dry, sharply pointed scales, which serve as pappus, and the whole mass of florets is encircled by a close involucre of leafy bracts. There are numerous varieties of the common sunflower in cultivation, the so-called double form being one in which the ordinarily tubular florets in the centre become spreading and "ligulate" like those at the circumference. The seeds, or more strictly speaking the fruits, contain much oil, for which the plant is cultivated in southern Russia. The oil is used in the manufacture of soap. The seeds are also valued for their agreeable flavour, and are much used as food for poultry, &c. The so-called "Jerusalem artichoke" (*Helianthus tuberosus*) belongs to the same genus. It is believed to be a native of Canada, or perhaps a modified form of *H. doronicoides*. The tubers are rich in inulin and sugar, and the plant deserves more attention at the hands of cultivators than it has yet received. The word "Jerusalem" is evidently a corruption, while "artichoke" applies to the flavour of the tuber, which is not unlike that of the artichoke.

SUNNITES AND SHÍ'ITES. The religion of Mohammed is at present professed by 150 to 200 million souls, spread over great parts of Asia (including the Indian Archipelago), Africa, and southern Europe,[1]—over Asia Minor, Armenia, Syria, Palestine, Arabia, Mesopotamia, the Caucasus, Persia, all upper Asia (including Siberia), the steppes of southern Russia, Afghanistan, Beluchistan, Tibet, China, Japan, India, Egypt, the Soudan as far as the equatorial lakes, the whole north coast of Africa and thence deep into the interior, European Turkey, Bulgaria, Bosnia, and Herzegovina. In most of these regions Moslems live side by side with men of other confessions, even where Islam is the ruling creed; it is found unmixed in Central Asia and some parts of Arabia. Geographical distribution.

Mohammedans fall into the two great divisions of Sunnites and Shí'ites (Shí'a), separated by such bitter hatred as belongs to two hostile religions, or such as some Catholic populations feel towards a Protestant.[2] The Sunnites, who accept the orthodox tradition (*Sunna*) as well as the Koran as a source of theologico-juristic doctrines, predominate in Arabia, the Turkish empire, the north of Africa, Turkestan, Afghanistan, and the Mohammedan parts of India and the east of Asia; the Shí'ites, whose origin has been explained in MOHAMMEDANISM (vol. xvi. pp. 564, 568, 592), have their main seat in Persia, where their confession is the state religion, but are also scattered over the whole sphere of Islam, especially in India and the regions bordering on Persia, except among the nomad Tatars, who are all nominally Sunnite. Even in Turkey there are many native Shí'ites, generally men of the upper classes, and often men in high office. The Shí'ites are less numerous and less important than the Sunnites, but on the whole may amount to 20 millions.

SUNNITES.

Orthodox Islam preserves unchanged the form of doctrine established in the 10th century by Abú 'l-Ḥasan al-Ash'arí (see vol. xvi. p. 593, and also pp. 553 *sq.*, 592, 584). The attacks of rationalism, aided by Greek philosophy, were repelled and vanquished by the weapons of scholastic dialectic borrowed from the enemy; on most points of dispute discussion was forbidden altogether, Sunnite

[1] Exact statistics are unattainable because we lack details as to the great advances which Islam has recently made and is still making in Central Africa.

[2] Generally speaking the Sunnites are the more bitter party. The relation is least strained in India, where the Sunnites approach the Shí'ites in reverence for 'Alí, Ḥasan, and Ḥosain, and share the feasts of these saints.

and faith in what is written in Koran and tradition was enjoined without question as to how these things were true (bilá kaifa) Freer allegorical views, however, were admitted on some specially perplexing points, such as the doctrine of the eternity of the Koran, the crude anthropomorphisms of the sacred text, &c , and, since Mo'tazilite views had never taken deep root among the masses, while the caliphs required the help of the clergy, and from the time of Motawakkil (847 A D) became ever more closely bound to orthodox views, the freethinking tendency was thoroughly put down, and to the present day no rationalizing movement has failed to be crushed in the bud Philosophy still means no more than scholastic dialectic, and is the humble servant of orthodoxy, no man venturing on devious paths except in secret In the years 1872-78 the Afghan Jamál al-Dín, a professor in the Azhar mosque at Cairo, attempted to read Avicenna with his scholars, and to exercise them in things that went beyond theology, bringing, for example, a globe into the mosque to explain the form of the earth But the other professors rose in arms, forbade him to enter the mosque, and in 1879 procured his exile on the pretext that he entertained democratic and revolutionary ideas Thus the later movements of thought in Islam never touch on the great questions that exercised Mohammedanism in its first centuries, *e g*, the being and attributes of God, the freedom of the will, sin, heaven and hell, &c Religious earnestness, ceasing to touch the higher problems of speculative thought, has expressed itself in later times exclusively in protest against the extravagances of the dervishes, of the worship of saints, and so forth, and has thus given rise to movements analogous to Puritanism

Ulema

That even in early times the masses were never shaken in their attachment to the traditional faith, with all its crude and grotesque conceptions, is due to the zeal of the ulema, or clergy, for the protection of Islam from every alien influence Mohammedanism has no priesthood standing between God and the congregation, but Koran and Sunna are full of minute rules for the details of private and civil life, the knowledge of which is necessarily in the hands of a class of professed theologians These are the *'ulemá* ("knowers," singular *'álim*), theology being briefly named "the knowledge" (*'ilm*) Their influence is still enormous and hardly has a parallel in the history of religions For it is not supported by temporal agencies like the spiritual authority of the Christian priesthood in the Middle Ages, but is a pure power of knowledge over the ignorant masses, who do nothing without consulting their spiritual advisers When the vigorous Spanish sultan Mansúr b Abí 'Ámir proposed to confiscate a religious foundation and the assembled ulema refused to approve the act, and were threatened by his vizier, one of them replied, "All the evil you say of us applies to yourself, you seek unjust gains and support your injustice by threats, you take bribes and practise ungodliness in the world But we are guides on the path of righteousness, lights in the darkness, and bulwarks of Islam, we decide what is just or unjust and declare the right, through us the precepts of religion are maintained We know that the sultan will soon think better of the matter, but, if he persists, every act of his government will be null, for every treaty of peace and war, every act of sale and purchase, is valid only through our testimony" With this answer they left the assembly, and the sultan's apology overtook them before they had passed the palace gate [1] The same consciousness of independent authority and strength still survives among the ulema Thus the sheikhu 'l-Islám 'Abbásí (who was deposed by the professors of the Azhar in 1882) had in the first period of his presidency a sharp conflict with 'Abbás Pasha, viceroy of Egypt, who asked of him an unjust legal opinion in matters of inheritance When bribes and threats failed, the sheikh was thrown into chains and treated with great severity, but it was the pasha who finally yielded, and 'Abbásí was recalled to honours and rich rewards

The way in which the ulema are recruited and formed into a hierarchy with a vigorous *esprit de corps* throws an instructive light on the whole subject before us The brilliant days are past when the universities of Damascus, Baghdád, Níshápúr, Cairo, Kairowán (Kairwan), Seville, Cordova, were thronged by thousands of students of theology, when a professor had often hundreds or even, like Bokharí, thousands of hearers, and when vast estates in the hands of the clergy fed both masters and scholars Of the great universities but one survives—the Azhar mosque at Cairo—where thousands of students still gather to follow a course of study which gives an accurate picture of the Mohammedan ideal of theological education [2]

Theological students

The students of theology generally begin their course in early youth, but not seldom in riper years Almost all come from the lowest orders, a few from the middle classes, and none from the highest ranks of society,—a fact which in itself excludes all elements of freer and more refined education These sons of poor peasants, artisans, or tradesmen are already disposed to narrow fanaticism, and generally take up study as a means of livelihood rather than from genuine religious interest The scholar appears before the president's secretary with his poor belongings tied up in a red handkerchief, and after a brief interrogatory is entered on the list of one of the four orthodox rites,—Sháfi'ite, Hanafite, Málikite, and Hanbalite If he is lucky he gets a sleeping-place within the mosque, a chest to hold his things, and a daily ration of bread The less fortunate make shift to live outside as best they can, but are all day in the mosque, and are seldom deserted by Moslem charity Having kissed the hands of the sheikh and teachers of his school, the pupil awaits the beginning of the lectures For books a few compendiums suffice him Professors and students gather every morning for the daily prayer, then the professors take their seats at the foot of the pillars of the great court and the students crouch on mats at their feet The beginner takes first a course in the grammar of classical Arabic, for he has hitherto learned only to read, write, and count. The rules of grammar are read out in the memorial verses of the Ajrúmíya, and the teacher adds an exposition, generally read from a printed commentary The student's chief task is to know the rules by heart, this accomplished, he is dismissed at the end of the year with a certificate (*ijáza*), entered in his text-book, which permits him to teach it to others The second year is devoted to dogmatic (*kalám* and *tawhíd*), taught in the same mechanical way The dogmas of Islam are not copious, and the attributes of God are the chief subject taken up. They are demonstrated by scholastic dialectic, and at the end of his second year the student, receiving his certificate, deems himself a pillar of the faith The study of law (*fikh*), which rests on Koran and tradition, is more difficult and complex, and begins, but is often not completed, in the third year The student had learned the Koran by heart at school and has often repeated it since, but only now is the sense of its words explained to him Of the traditions of the Prophet he has learned something incidentally in other lectures, he is now regularly introduced to their vast and artificial system. From these two sources are derived all religious and civil laws, for Islam is a political as well as a religious institution The five main points of religious law, "the pillars of Islam," have been

[1] Von Kremer, *Gesch d herrschenden Ideen d Islams*, Leipsic, 1868, p 464

[2] Of the 126 madrasa or colleges which once belonged to the university of Damascus but five remained in 1880

enumerated in vol xvi p 553 *sq*, the civil law, on the development of which Roman law had some influence, is treated under heads similar to those of Western jurisprudence It is here that the differences between the four schools (vol xvi p 594 *sq*) come most into notice the Hanafite praxis is the least rigorous, then the Sháfi'ite, the Hanbalites, whose system is the strictest, have practically disappeared in the Málikites The Hanafite rite is official in the Turkish empire, and is followed in all Government offices whenever a decision still depends on the sacred law, as well as by all Mohammedans of Turkish race In Egypt and North Africa Sháfi'ites are more numerous than Málikites, while the opposite is the case in Arabia In 1878 the Azhar had 7691 students,—3723 Sháfi'ites with 106 sheikhs, 2855 Málikites with 75 sheikhs, 1090 Hanafites with 49 sheikhs, 23 Hanbalites with 1 sheikh In this as in the previous studies a compendium is learned by heart, and explanations are given from commentaries and noted down by the students word for word The professors are expressly forbidden to add anything of their own The recognized books of jurisprudence, some of which run to over twenty folio volumes, are vastly learned, and occasionally show sound sense, but excel mainly in useless hair-splitting and feats of scholastic gymnastics, for which the Arabian race has a natural gift

Besides the three main disciplines the student takes up according to his tastes other subjects, such as rhetoric (*ma'ání wabayán*), logic (*mantik*), prosody (*'arúd*), and the doctrine of the correct pronunciation of the Koran (*kirá'a watajwíd*) After three or four years, fortified with the certificates of his various professors, he seeks a place in a law-court or as a teacher, preacher, cadi, or mufti of a village or minor town, or else one of the innumerable posts of confidence for which the complicated ceremonial of Mohammedanism demands a theologian, and which are generally paid out of pious foundations A place is not hard to find, for the powerful corporation of the ulema seeks to put its own members into all posts, and, though the remuneration is at first small, the young 'álim gradually accumulates the revenues of several offices Gifts, too, fall in, and with his native avarice and economy he rises in wealth, position, and reputation for piety The commonalty revere him and kiss his hand, the rich show him at least outward respect, and even the Government treats him as a person to whom consideration is due for his influence with the masses

This sketch of his education is enough to explain the narrow-mindedness of the 'álim He deems all non-theological science to be vain or hurtful, has no notion of progress, and regards true science—*i e*, theology—as having reached finality, so that a new supercommentary or a new students' manual is the only thing that is perhaps still worth writing How the mental faculties are blunted by scholasticism and mere memory work must be seen to be believed, such an education is enough to spoil the best head All originality is crushed out and a blind and ludicrous dependence on written tradition—even in things profane—takes its place Acuteness degenerates into hair-splitting and clever plays on words after the manner of the rabbins The Azhar students not seldom enter Government offices and even hold important administrative posts, but they never lose the stamp of their education—the narrow unteachable spirit, incapable of progress, always lost in external details, and never able to grasp principles and get behind forms to the substance of a matter (W S -B)

Schools

Yet it is but a small fraction of the ulema of the Moslem world that enjoy even such an education as the Azhar affords It draws few students from foreign parts,[1] where the local schools are of the poorest kind, except in India (thanks to the British Government) and perhaps in Constantinople[2] Bokhárá was once a chief seat of learning, but is now so sunk in narrow fanaticism that its eighty *madrasas* with their 5000 students only turn out a bigoted and foolish clergy (Vámbéry)[3] But for this very reason Bokhárá is famed as a luminary of pure theology and spreads its influence over Turkestan, Siberia, China, Kashmir, Afghanistan, and even over India Minor schools attached to mosques are found in other places, but teach still less than the great schools already mentioned

Caliphate and temporal sovereignty

Except in India, where it is controlled by the Government, the organization of the priestly and judicial persons trained in the schools is a compromise between what theological principles dictate and what the state demands Neither Koran nor Sunna distinguishes between temporal and spiritual powers, and no such distinction was known as long as the caliphs acted in all things as successors of the prophets and heads of the community of the faithful But, as the power of the 'Abbásids declined (see vol xvi p 585 *sq*) and external authority fell in the provinces into the hands of the governors and in the capital into those of the *amír al-omará*, the distinction became more and more palpable, especially when the Búyids (Buwaihids), who were disposed to Shí'ite views, proclaimed themselves sultans, *i e*, possessors of all real authority The theologians tried to uphold the orthodox theory by declaring the sultanate to be subordinate to the imámate or sovereignty of the caliphs, and dependent on the latter especially in all religious matters, but their artificial theories have never modified facts The various dynasties of sultans (Búyids, Ghaznevids, Seljúks, and finally the Mongols) never paid heed to the caliphs and at length abolished them, but the fall of the theocracy only increased the influence of the clergy, the expounders and practical administrators of that legislation of Koran and Sunna which had become part of the life of the Mohammedan world The Mamelukes in Egypt tried to make their own government appear more legitimate by nominally recognizing a continuation of the spiritual dignity of the caliphate in a surviving branch of the 'Abbásid line which they protected, and in 923 A H (1517) the Ottoman Selim, who destroyed the Mameluke power, constrained the 'Abbásid Mutawakkil III, who lived in Cairo, to make over to him his nominal caliphate The Ottoman sultans still bear the title of "successors of the Prophet," and still find it useful in foreign relations, since there is or may be some advantage in the right of the caliph to nominate the chief cadi (*kádí*) of Egypt and in the fact that the spiritual head of Khiva calls himself only the *nakíb* (vicegerent) of the sultan[4] In India too the sultan owes something perhaps to his spiritual title But among his own subjects he is compelled to defer to the ulema and has no considerable influence on the composition of that body He nominates the *sheikhu 'l-Islám* (senior, *i e*, president of Islam) or mufti of Constantinople (grand mufti), who is his representative in the imámate and issues judgments in points of faith and law from which there is no appeal, but the nomination must fall on one of the *mollahs*,[5] who form the upper stratum of the hierarchy

[1] In 1878 seventeen lecture rooms of the Azhar had 3707 students, of whom only 64 came from Constantinople and the northern parts of the Ottoman empire, 8 from North Arabia, 1 from the government of Baghdád, 12 from Kurdistan, and 7 from India with its thirty million Sunnites

[2] In Kazan also the standard of learning seems to have been raised by Russian and Western scholars

[3] The *madrasa* is here a college, generally attached to a mosque, with lands whose revenues provide the means of instruction and in part also food and residence for scholars and teachers

[4] Till the Russians gained preponderating influence the khán of Khiva also acknowledged the sultan as his suzerain

[5] Mollah is the Perso Turkish pronunciation of the Arabic *maulá*, literally "patron," a term applied to heads of orders and other religious dignitaries of various grades

of ulema. And, though the various places of religious dignity are conferred by the sultan, no one can hold office who has not been examined and certified by older ulema, so that the corporation is self-propagating, and palace intrigues, though not without influence, can never break through its iron bonds. The deposition of 'Abd al-Azíz is an example of the tremendous power that can be wielded by the ulema at the head of their thousands of pupils[1] when they choose to stir up the masses; nor would Mahmúd II. in 1826 have ventured to enter on his struggle with the Janissaries unless he had had the hierarchy with him.

The student who has passed his examinations at Constantinople or Cairo may take up the purely religious office of *imám* (president in worship) or *khatíb* (preacher) at a mosque. These offices, however, are purely ministerial, are not necessarily limited to students, and give no place in the hierarchy and no particular consideration or social status. On the other hand, he may become a judge or cadi.

Judicial offices

Every place of any importance has at least one cadi, who is nominated by the Government,[2] but has no further dependence on it, and is answerable only to a member of the third class of the ulema, viz., the mufti or pronouncer of *fetwas*. A fetwa is a decision according to Koran and Sunna, but without reasons, on an abstract case of law which is brought before the mufti by appeal from the cadi's judgment or by reference from the cadi himself. For example, a dispute between master and slave may be found by the cadi to turn on the general question, "Has Zaid, the master of 'Amr,[3] the absolute right to dispose of his slave's earnings?" When this is put to the mufti, the answer will be simply "Yes," and from this decision there is no appeal, so that the mufti is supreme judge in his own district. The grand mufti of Constantinople is, as we have seen, nominated by the sultan, but his hold on the people makes him quite an independent power in the state; in Cairo he is not even nominated by the Government, but each school of law chooses its own sheikh, who is also mufti, and the Hanafite is head mufti because his school is official in the Turkish empire.

Modern changes

All this gives the judges great private and political influence. But the former is tainted by venality, the plague-spot of the East, which, aggravated by the scantiness of judicial salaries or in some cases by the judge having no salary at all, is almost universal among the administrators of justice. Their political influence, again, which arises from the fusion of private and political law in Koran and Sunna, is highly inconvenient to the state, and often becomes intolerable now that relations with Western states are multiplied. And even in such distant parts as Central Asia the law founded on the conditions of the Prophet's lifetime proves so unsuited to modern life that cases are often referred to civil authorities rather than to canonical jurists. Thus a customary law (*'orf*) has there sprung up side by side with the official sacred law (*sharí'a*), much to the displeasure of the mollahs. In Turkey, and lately above all in Egypt, it has been found necessary greatly to limit the sphere and influence of the canonical jurists and introduce institutions nearer to Western legal usage. We do not here speak of the paper constitutions (*khatt-i-sherif*) and the like, created to dupe Western diplomatists and amuse their authors, but of such things as consular and commercial courts, criminal codes, and so forth. The present sultan seems also to aim at diminishing the power of the ulema by such measures as frequent changes of the sheikhu 'l-islám, though this policy is perhaps less likely to confirm his power than to rob it of its last supports.

The official hierarchy, strong as it is, divides its power with the dervishes. A religion which subdues to itself a race with strongly marked individuality is always influenced in cultus and dogma by the previous views and tendencies of that race, to which it must in some measure accommodate itself. Mohammed himself made a concession to heathen traditions when he recognized the Kaaba and the black stone; and the worship of saints, which is now spread throughout Islam and supported by obviously forged traditions, is an example of the same thing. So too are the religious orders now found everywhere except in some parts of Arabia. Mystical tendencies in Mohammedanism arose mainly on Persian soil (see vol. xvi. p. 594), and Von Kremer has shown that these Eastern tendencies fell in with a disposition to asceticism and flight from the world which had arisen among the Arabs before Islam under Christian influence.[4] Intercourse with India had given Persian mysticism the form of Buddhistic monkery, while the Arabs imitated the Christian anchorites; thus the two movements had an inner kinship and an outer form so nearly identical that they naturally coalesced, and that even the earliest organizations of orders of dervishes, whether in the East or the West, appeared to Mohammedan judgment to be of one type. Thus, though the name of *Súfí* (see vol. xvi. p. 594) is first applied to Abú Háshim, who died in Syria in 150 A.H. (767), we find it transferred without question to the mystical brotherhood which appears in Khorásán under Abú Sa'íd about 200 A.H. (815/6). Yet these two schools of Súfís were never quite similar; on Sunnite soil Ṣúfism could not openly impugn orthodox views, while in Persia it was saturated with Shí'ite heresy and the pantheism of the extreme devotees of 'Alí (see vol. xvi. p. 593). Thus there have always been two kinds of Súfís, and, though the course of history and the wandering habits which various orders borrowed from Buddhism have tended to bring them closer to one another, we still find that of the thirty-six chief orders three claim an origin from the caliph Abúbekr, whom the Sunnites honour, and the rest from 'Alí, the idol of the Shí'ites.[5] Mystic absorption in the being of God, with an increasing tendency to Pantheism and ascetic practices, are the main scope of all Ṣúfism, which is not necessarily confined to members of orders; indeed the secret practice of contemplation of the love of God and contempt of the world is sometimes viewed as specially meritorious. And so ultimately the word *ṣúfí* has come to denote all who have this religious direction, while those who follow the special rules of an order are known as dervishes ("beggars," in Arabic *fukará*, sing. *fakír*—names originally designating only the mendicant orders). In Persia at the present day a Ṣúfí is much the same as a freethinker. Several of the chief dervish orders arose in the evil times before and after the invasion of the Mongols: thus 'Abd al-Kádir al-Jílání (d. 561 A.H.; 1165/66) founded the Kádiríya order, Ahmad al-Rifá'í (d. 578 A.H., 1182/3) the Rifá'íya, Jalálu 'l-dín Rúmí (see RÚMÍ) the Mawlawíya, Abú 'l-Hasan al-Shádhilí (d. 656 A.H., 1258) the Shádhilíya, Ahmad al-Badawí (d. 675 A.H., 1276) the Ahmadíya or Badawíya, an order still very widely spread in Egypt. While civil distress drove men to flee from the world, the stupid fanaticism of Turkish rule has helped on the belief in miracles so often associated with mysticism and all those deceits that go with the spread of enthusiastic notions. Of later orders we may name the

Súfís and dervishes

[1] Called in Constantinople *softa*, Persian *sókhta*, "burned up," *scil.*, with zeal or love to God.

[2] In Egypt before the time of Sa'íd Pasha (1854-63) the local judges were appointed by the chief cadi of Cairo, who is sent from Constantinople. Since then they have been nominated by the Egyptian Government.

[3] Zaid and 'Amr are the Caius and Sempronius of Arabian law.

[4] *Op. cit.*, p. 52 *sq.*

[5] These claims to early origin are mere fables, like the claim of the Oweisí order to spring from Oweis, one of the oldest traditionalists, and so forth.

Nakshbendíya, now the most important in the khanates of Turkestan, whose founder died 719 A H (1319), the Sa'díya (736 A H , 1335), the Bektashíya (758 A H , 1357), the Khalwatíya (800 A H , 1397)[1]

The modern dervishes have sunk as low as the modern ulema The idea of absorbed contemplation of the divine being, freed from all earthly conceptions, and of mortification of the flesh in order to become one with God is grossly caricatured in the insane howlings *hu hu* ("he, he") and self-torture with red-hot knives, &c, practised by the "howling" Rifa'íya and in the dizzy whirling of the "dancing" Mawlawíya Very pestilent too is their traditional reputation for holiness with the common people, while ecstatic piety easily passes into deceit where it is still generally believed that a saint (*walí*) can work miracles The wandering dervishes especially, who move constantly from place to place, are noted for all sorts of juggling impostures, by the aid of which, like the Yogis of India, they live at the cost of the people[2] But they are no longer trusted or held in much esteem even by the populace, whereas the conventual orders are usually regarded as pious and inspired men Sheikh Ahmad, the founder of the Badawíya, is the national saint of Egypt, and his tomb at Tanta is a great place of pilgrimage The ulema dislike these rivals, but can do little against their influence

The bright side in the modern world of Islam is found among the lower classes The ruling classes of Turkey are utterly corrupt, and for centuries their one art of administration has been to suck the provinces dry Taxes are exorbitant and bad laws check the production of wealth, while what remains of the useful institutions and public works of old time daily decays To this is added the recklessness born of a more or less clear consciousness that things cannot last as they are The effendi of Constantinople has lost faith in his religion and the future of his race, as for a sense of honour, as we understand it, that does not exist in the East In Egypt things have not been quite so bad since Mohammed 'Alí destroyed the Mamelukes and founded a state with some pretensions to order and solidity, selfish as he was, he saw that to maintain the revenue it was necessary to stimulate production, and to this end, amid many mistakes, he took not a few useful steps His successors were less wise and skilful, yet prosperity increased, and for the first time for centuries national feeling began to assert itself But this movement fell into the hands of the ignorant and fanatical 'Orábí Pasha (1882) and led to the English occupation and the entire disorganization of the country, so that Cairo is now little better than Constantinople

Poorer classes

Yet with all this the poorer classes have not lost their vigour, and among them Islam has still a deep-rooted strength The common Turk of Roumelia or Asia Minor is still a solid sober honest fellow and a brave soldier, always ready to make every sacrifice for his religion In Egypt the morality of the people has suffered from the great foreign immigration, which has introduced many evil elements as well as some good, yet even here the great mass of both townsmen and peasants are loyal to the old faith and to the traditional sobriety and parsimony which the nature of the country itself prescribes These qualities taken with the undoubted intelligence of the Arabian population give hope of a revival of prosperity on the Nile under more favourable political conditions The people have a persuasion of the superiority of their religion, which, while it often makes necessary reforms difficult, prevents them from losing national individuality and self reliance, and the belief in predestination gives a certain dignity and self possession under calamities, without excluding foresight and activity in daily duty But whether all this is enough to secure the political revival of the Sunnite commonwealths is doubtful in face of the preponderating influence on all the coasts of the Levant of Western civilization, which as yet is almost entirely a disintegrating force and seems certain to prevent a reintegration of Islam in Turkey, and probably also in Egypt The khanates, again, are sunk in incredible moral corruption cloaked by blind fanaticism, while most of the Bedouin tribes of Arabia have known little about Koran and religion for the last eight centuries[3] Islam has certainly still a great future in Central Africa, but this can hardly lead to veritable reformation of its system Still there are many evidences that the faith is not yet dead even in its old realms We lay no stress on the existence of various sects opposed to the current Sunnite orthodoxy, such as the puritanical Wahhabites of Arabia and India, or the DRUSES (*q v*), Nosairíya, Isma'ílíya, and Metwálíya of Syria, who are tinged with Shí'ite views and belong only politically to the Sunnite section of Islam But in India there are still living seeds of further development within Islam proper Under English control the ulema are unable to maintain the same spiritual tyranny over men's minds as elsewhere, and we find more mutual toleration between Sunna and Shí'a, an easy accommodation to local tradition,[4] and even an ability to leave the grooves of Al-Ash'arí's scholasticism and approach the ideas of the old rationalistic Mo'tazilites Movements in this direction have come to light quite recently, but their further growth need not here be speculated on[5]

SHI'ITES

The extreme Shí'ite view that 'Alí is to be regarded as an incarnation of the Godhead (see vol xvi pp 568, 592) maintained its predominance only in times when and places where the opposition to the sovereignty of the Omayyads and 'Abbásids was intense, or where pantheistic influences from India were at work From the first there existed also a milder form of Shí'ite faith, which soon was at open war with the fanatical Ismá'ílíya and their disciples, the Fátimites and Assassins (vol xvi p 593 *sq*)[6]

It was through the moderate Shí'ites that the caliph Ma'mún thought to reconcile his dynasty with the house of 'Alí (vol xvi p 584), and it was this party that became dominant in Persia in the 10th Christian century under the Búyids When they conquered Baghdád the Búyids abstained from interfering with the Sunnite orthodoxy of the populations of the capital and Arabian 'Irák, but the Shí'ite faith was openly professed in their courts at Rai, Shiráz, and Kirmán But in the next century the power of the Shí'ite dynasty crumbled and fell before the Ghaznevids and Seljúks, who as Turks were Sunnites, and repressed the opposing views In the 13th century the Mohammedan East was overrun by the Mongols, who at first were indifferent to all religion, and gave the Persian Shí'ites perfect liberty, later on the great-grandson of Jenghis Khán, Mohammed Khodahbende Oeljitu (1303-16),

Shí'ite dynasties in Persia.

[1] The best account of the dervishes is still that in D'Ohsson, *Tableau Général de l'Emp Ottoman*, vol ii , Paris, 1790

[2] These mendicants belong in part to orders like the Bektashíya and Rifá'íya, whose other members live in convents (Khangah, Takíya), in part they are Kalanderíya (Calanders), *i e*, bound by the rule of Kalander, a disciple of Bektash, which enjoins constant wandering

[3] *Sefer Nameh*, ed Schefer, Paris, 1881, pp 30 *sq*, 233

[4] See Garcin de Tassy, "Sur les particularités de la rel mus dans l'Inde," reprinted in *L'Islamisme*, 3d ed , Paris, 1874, pp 290 *sq*, 296 *sq* The Wahhabites protest against this laxity

[5] See Syed Ameer 'Alí, *Personal Law of Mohammedans*, London, 1880, preface

[6] When the Fátimite lords of Egypt tried to enter into relations with the moderate Shí'ite Búyids in Baghdád they were met with polite reserve, and subsequently public protests against them emanated from the 'Alide circles of that city (Wustenfeld, *Geschichte der Fatimiden Chalifen*, Gottingen, 1881, pp 197, 237)

himself became a Shí'ite; nor was the progress of the sect checked by the fall of the dynasty and the conquests of Tímúr (1387), who veiled his religious indifference by proclaiming himself an admirer of 'Alí. Thus the mass of the Persian population remained Shí'ites, and the Tímúrides accommodated themselves to the religious feelings of their subjects. Tímúr's son, Sháh Rokh, even built and furnished forth the tomb of the imám Rizá in Meshhed (Meshed). The troublous times that followed and the intervention in Persian affairs of the Sunnite Ak-Koyunlu (see vol. xviii. p. 632 *sq.*) must have been unfavourable to Shí'ite principles; but they gained a final victory through the Safawí dynasty, whose founder, Sháh Ismá'íl (1499-1523), gave the Shí'ite doctrine, in the form in which it is held by the Ithná-'Ashariya, the position it still has as the state religion of Persia.

The Ithná 'Ashariya. The Ithná-'Ashariya, or "Twelvers," a sect of the moderate Shí'ites, have their name from the respect they pay to 'Alí and his eleven immediate heirs through Fátima, daughter of the Prophet. Like all Shí'ites, they hold that 'Alí was designated as his successor by Mohammed,[1] and unjustly thrust aside by the three actual caliphs, Abúbekr, 'Omar, and 'Othmán. Still more do they hate the Omayyad enemies of 'Alí and his house (see vol. xvi. p. 563). They and the 'Abbásids were usurpers, the true caliphs *de jure* being the imáms—(1) 'Alí; (2) Hasan; (3) Hosain; then his heirs in the direct line—(4) 'Alí II.; (5) Mohammed al-Bákir; (6) Ja'far al-Ṣádik; (7) Músá al-Kázim; (8) 'Alí III. al-Ridá (in modern pronunciation Riza); (9) Mohammed II. al-Jawád; (10) 'Alí IV. al-'Askarí; (11) Hasan II. al-Khamt; (12) Mohammed III. al-Mahdí, who lived in the second half of the 3d century of the Flight (9th century A.D.), and to whom his Shí'ite partisans looked to free them from the 'Abbásid yoke. These hopes failed and he himself disappeared, whence the belief grew that he was concealed in a cave at Samarra and would return at the end of days. Meantime the sovereignty belongs to the other descendants of 'Alí, the Sayyids (lords). In fact the Safawís claimed descent from the seventh imám, and neither the Afghan Nadir Sháh, who overthrew their power, nor the Kajars, who now reign, are regarded as legitimate. The false position which the royal house stands in with the clergy is an important element in the weakness of the crumbling state of Persia.

Shí'ite tenets. All other points in which Shí'ites differ from Sunnites depend on their legitimistic opinions, or are accommodations of the rites of Islam to the Persian nationality, or else are petty matters affecting ceremonial. The rejection of the whole Sunnite traditions goes with the repudiation of the caliphs under whose protection these were handed down.[2] An allegorical and mystical interpretation reconciles the words of the Koran with the inordinate respect paid to 'Alí; the Sunnite doctrine of the uncreated Koran is denied. To the Mohammedan confession "There is no god but God and Mohammed is His ambassador" they add "and 'Alí is the vicegerent of God" (*walí*, properly "confidant"). There are some modifications in detail as to the four main religious duties of Islam,—the prescriptions of ritual purity, in particular, being absurdly exaggerated and made the main duty of the faithful. The prayers are almost exactly the same, but to take part in public worship is not obligatory, as there is at present no legitimate imám whose authority can direct the prayer of the congregation. Pilgrimage to Mecca, to which the Sunnite indwellers of 'Irák and Arabia oppose difficulties, though since the reign of 'Abd al-Mejíd it is officially thrown open to all, may be performed by a hired substitute,[3] or its place can be taken by a visit to the tombs of Shí'ite saints, *e.g.*, that of 'Alí at Nejef, of Hosain at Kerbelá, of Rizá at Meshhed, or of the "unstained Fátima" at Kum (Fátima-i-ma'asúm, daughter of Músá, the 7th imám). The Shí'ites are much the most zealous of Moslems in the worship of saints (real or supposed descendants of 'Alí) and in pilgrimages to their graves, and they have a characteristic eagerness to be buried in those holy places. The Persians have an hereditary love for pomps and festivities, and so the Shí'ites have devised many religious feasts. Of these the great sacrificial feast (*'íd-i-Kurbán*; Turkish *Kurbán Bairám*) is also Sunnite; the first ten days of the month Moharram are dedicated to the mourning for the death of Hosain at Kerbelá (vol. xvi. p. 568), which is celebrated by passion-plays (*ta'ziya*; see vol. xviii. p. 660), while the universal joy of the Nauroz, or the New Year of the Old Persian calendar, receives a Mohammedan sanction by the tradition that on this day the Prophet conferred the caliphate on 'Alí.[4]

While they naturally reject the four Sunnite schools of jurisprudence, the Shí'ites also derive all law from the Koran, and their trained clergy (mollahs) are the only class that can give legitimate legal responses. The training of the mollah resembles that of the Sunnite 'álim. The course at the madrasa embraces grammar, with some rhetoric and prosody, logic, dogmatic, Koran exegesis, tradition, and jurisprudence, and finally some arithmetic and algebra. The best madrasa is at Kerbelá.[5] But the best students of Kerbelá are no match even for the Sunnite disciples of Bokhárá.[6] The scholar discharged from his studies becomes first a simple mollah, *i.e.*, local judge and notary.[7] A small place has one such judge, larger towns a college of judges under a head called the *sheikhu 'l-Islám*. The place of the Sunnite muftis is filled by certain of the *imám-jum'a*, *i.e.*, presidents of the chief mosques in the leading towns, who in respect of this function bear the title of *imám mujtehid*. This is a dignity conferred by the tacit consent of people and clergy, and is held at one time only by a very few distinguished men. At the beginning of the 19th century there were but five mujtehids in Persia; now (1887) they seem to be more numerous. In Persia the cadi (*kázi*) is an inferior judge who acts for the sheikhu 'l-Islám in special cases, and a mufti is a solicitor acting under the judge to prepare cases for court.

Ecclesiastical officers.

Judicial officers.

Under the Safawís, when the clergy had great influence, they had at their head the *ṣadru 'ṣṣodúr*, who administered all pious foundations and was the highest judicial authority. But so great a power was found dangerous; 'Abbás the Great (1586-1628) abstained from filling up a vacancy which occurred in it, and, though Sháh Sefí (1628-1641) restored the office, he placed it in commission. Nádir Sháh abolished it in his attempt to get rid of the Shí'ite hierarchy (1736), and since then it has not been restored. Yet the imám-jum'a of Ispáhán, the old Safawí capital, is tacitly regarded as representative of the invisible imám of the house of 'Alí, who is the true head of the church. Various vain attempts have been made in the 19th century to subordinate the authority of the clergy to the Government. These attempts had the sympathy of the better classes,

[1] To make this credible divers passages of the Koran have been changed from the received readings, and ultimately a special súra was forged out of Koran phrases. See Noldeke, *Gesch. des Qorans*, p. 220 *sq.*

[2] But the comparison of Shí'ites with Protestants is futile. Shí'ites have their own tradition (*hadís*) referred to 'Alí, which is grossly distorted,—indeed a tissue of lies.

[3] This the Sunnites also allow under certain conditions.

[4] Without this sanction the Nauroz was celebrated even at court under the 'Abbásids. It is the only feast still celebrated by the poor as well as the rich.

[5] On Turkish soil; but the Shí'ite foundations there are tolerated.

[6] Polak, *Persien*, Leipsic, 1865, i. 290.

[7] No contract, especially no contract of marriage, is valid unless made before a mollah. An ordinary inferior judge is called *darúgha*.

for the venality and moral corruption of the mollahs and their disposition to the most vulgar fraud are proverbial. But, on the other hand, the clerical power and the right of asylum at Meshhed, Kum, and some other sanctuaries are the only protection of the masses against the arbitrary tyranny of the court and the officials. There is now a sort of truce between the Government and the clergy, though the former is always suspicious of the latter. Only the venality of the spiritual courts has led, as in Turkestan, to a limitation of their jurisdiction, and judicial decisions are given also by civil magistrates according to *'orf* or customary law and, although their decisions are often arbitrary, they are commonly resorted to in cases affecting property, in which the spiritual judge would think it his duty to "eat up" the sum in dispute. The main prop of the mollahs against the Government are the scum of the population, the *lútís* or foul rowdies. In 1862, according to Vámbéry, the imám-jum'a of Ispáhán had at his orders a thousand of these scoundrels.

Dervishes. The rivals of the clergy in popular influence are the dervishes, whose show of holiness cloaks an immorality and propensity to crime far exceeding what is found among their brethren in Egypt and Turkey. So it has been for centuries, as appears in Olearius's account of the Calanders of his time (1637). Supported by popular superstition, the Persian dervishes are much more pretentious than those of the West. At the great feasts especially they quarter themselves impudently in wealthy houses and deafen the indwellers with their unceasing cry of *Yá hakk* ("O Truth!" the mystical equivalent of "O God!"). The wise and modest dervish who in Sa'di's poems tells the greatest sultan the truth as to the hollowness of his royal state has degenerated into the half-mad and insolent hanger-on who thrusts himself into audience-chambers and claims the seat of honour beside the grandees. The multitude of these motley vagabonds, some harmless, others dangerous, is explained by the love for idleness, buffoonery, and story-telling, which is even more marked in Persia than in other parts of the East.

Religious observance by both sects. The great practical difference between the Sunnite and Shí'ite communities is that among the former it is only with the upper classes, who are few in number, and with the worse sort of dervishes that obedience to the precepts of religion is a mere formal profession. Most of the ulema and the middle and lower classes are sincere Moslems. In Persia it is the other way; the praise of religion is always on men's lips, but the inner conviction is that it is all a mockery. The clergy laugh inwardly at their own functions; the educated classes either believe nothing at all or hold secretly to a Súfí pantheism. Sa'dí and Háfiz are much more to them than the Koran, and, while the Sunnite takes his *sortes biblicæ* from the Koran, the Shí'ite uses a copy of the songs of Háfiz. With the common people it is not the proper precepts of Islam, but the Shí'ite tenets directed against Sunnites and Jews, that find hearty adherence. The death-feast of Hasan and Hosain excites them far more than the great sacrificial feast; and 'Alí, the national saint, is much more popular than Mohammed. Islam, as it was forced on Persia by 'Omar, was the faith of foreign conquerors and oppressors; and the people have revenged themselves by travestying it and veiling their old convictions under its outward forms. And so Islam has never had any considerable influence on conduct save that it has confirmed the natural turn of the Persians for lying and hypocrisy. As it was long necessary to profess orthodoxy for fear of the Arabs, it came to be an established Shí'ite doctrine that it is lawful to deny one's faith in case of danger. This "caution" (*takíya*) or "concealment" (*ketmán*) has become a second nature with the Persians. And with this it goes that no one shrinks from secret sins, though outwardly professing the utmost devotion. The preparation of wine and spirits, for example, is confined to Jews and Armenian Christians, but private drunkenness is most common. Very conscientious or pious people, however—*e.g.*, the dervishes—use rather opium or *hashísh* and confound the narcotic intoxication with mystic ecstasy. Another mischievous thing is the permission of temporary marriages,—marriages for a few hours on a money payment. This legitimized harlotry (*mot'a*) is forbidden by the Sunna, but the Shí'ites allow it, and the mollahs adjust the contract and share the women's profits.

With all this, modern observers are agreed that the middle and lower classes of Persia are not hopeless, and that their natural intelligence, though combined with lack of perseverance, would make it much easier for them than for the Turks to take a new start if they were freed from the wretched civil and ecclesiastical administration. There is still mental life and vigour among them, as appears—though in an unfavourable aspect—among the sects, which, allowance being made for "takíya," play no inconsiderable part. Shí'ite sects. The Akhbárís (traditionalists), who adopt a semi-philosophical way of explaining away the plainest doctrines (such as the resurrection of the flesh) on the authority of false traditions of 'Alí, are not so much a sect as a school of theology within the same pale as the orthodox Shí'a or *mujtehidís*.[1] A real dissenting sect, however, is the Sheikhís, of whose doctrines we have but imperfect and discrepant accounts.[2] Representatives of the old extreme Shí'ites, who held 'Alí for a divine incarnation, are found all over Persia in the 'Alí-Iláhí or 'Alí-Alláhí sect ("'Alí deifiers").[3]

Bábí movement. Finally, in the year 1848 there broke out a violent reaction against the wretched condition of state and church at a moment when a new succession to the throne had (as is wont) involved great part of the land in anarchy (comp. vol. xviii. p. 651). As early as 1837 a young enthusiast, 'Alí (son of) Mohammed, imbued with pantheistic and communistic ideas,[4] had begun a peaceable but zealous propaganda. Consistently enough with ultra-Shí'ite principles, he deemed himself inspired by the spirit of God, and claimed to be the Mahdí, the twelfth imám, issued from his obscurity to lead the world to salvation. He took the title of Báb al-dín ("portal of the faith"), and his followers are known as Bábís. Báb was a man of profound sincerity and averse to violent measures; he avoided all open polemic against the Government, which in turn at first tolerated him in its jealousy of the clergy. In 1844 the too great zeal of his follower Mollah Hosain occasioned Báb's imprisonment; but Hosain and his emissaries continued the propaganda and made many converts in all provinces. When the troubles of 1848 broke out Hosain raised open rebellion in Mazenderán. Terrible conflicts ensued, made only more bitter by the execution of Báb (18th July 1849). Apparently suppressed, the movement proved that it was not extinct in an attempt to assassinate the sháh in 1852. A new proscription followed; but there is no doubt that Bábism still lives in secrecy, and the universal sympathy

[1] The orthodox are so called because they allow the authority of the mujtehid (*supra*, p. 664). See Gobineau, *Les Religions, &c., dans l'Asie Centrale*, Paris, 1866, p. 28 *sq.*

[2] Gobineau (*op. cit.*, p. 30) reckons them as orthodox; but see Polak, *Persien*, Leipsic, 1865, i. 348; comp. also Von Kremer, *Gesch. d. herrschenden Ideen des Islams*, p. 206 *sq.* (after Kazem Beg).

[3] See Polak, *op. cit.*, p. 349; Malcolm, *Hist. of Persia*, ii. 382; Rehatsek, in *Journ. R. S. A.* (Bombay branch), 1880, p. 424. Langlès, in Chardin, *Voyages*, 1811, x. 241, says that at the beginning of the 19th century their chief seats were north of Kandahar and Kabul (Cabul), and at Kashan.

[4] The fusion of these two tendencies is in Persia as old as Mazdak (vol. xviii. p. 611). Communistic risings constantly took place in various parts of Persia under the caliphs, and that of Bábek endangered the empire for twenty years (till 837 A.D.). The communists were afterwards absorbed in the Ishmaelites (see vol. xvi. p. 593 *sq.*), whose power was extinguished by the Mongols (1256).

felt for the martyr Báb among generously minded Persians may still give it a future.[1]

Less dangerous than these bold communists are the Ishmaelites, direct descendants of the old Ismá'ílíya, whose nihilist doctrines are now diluted into a harmless doctrine of incarnation. They are pretty numerous in India, at Bombay, Surat, and Burhampur, but hardly are found in Persia.[2]

Despite their mutual feuds, Sunnites and Shí'ites are at one in their hatred and contempt for the professors of other religions. Holding that faith and unbelief are matter of predestination, Islam is not given to forcible proselytizing, and on certain conditions Christians and Jews (and later on Zoroastrians also) have always been tolerated in the Mohammedan empire, except that 'Omar, mainly on political grounds, expelled all non-Moslems from Arabia. But none the less the adherents of other faiths are hated and despised as children of hell and enemies of true religion. To reconcile the present decay of Islam and prosperity of the unbeliever with their feelings and convictions, Sunnites and Shí'ites alike take refuge in the doctrine of a restoration of Islam before the end of the world through the

Coming of the Mahdi.

"divinely guided" Mahdí. In view of the interest in the subject excited by recent events, some addition may here be made to the brief statement in the article MAHDI.[3] Originally, as has been shown in that article, the idea of a god-sent deliverer from the illegitimate caliphs was attached by the Shí'ites to actual pretenders of the house of 'Alí; but later on, and especially since the days of the Mongols, the figure of the Mahdí was projected into the far future, and ultimately his arrival was made a sign of the end of the world. Among the Sunnites, on the other hand, who could not accept the Shí'ite pretenders, some of those who felt that the Omayyad sovereignty was not truly spiritual and worthy of Islam borrowed the Christian hope of the second coming of Christ, whom Islam acknowledges as a prophet and precursor of Mohammed, and whose return at the end of the world seemed to accord with some vague passages of the Koran; others looked, like the Shí'ites, for a deliverer from earthly tyranny, but did not tie themselves to the belief that he must spring from the house of 'Alí. When the theologians of 'Abbásid times began to systematize the religious traditions they found some that spoke of a return of Jesus and others referring to a Mahdí. These they combined together, so that Sunnites now believe that, when unrighteousness is at its height upon earth and the victory of the enemies of Islam seems sure, the Mahdí will appear to destroy the unbelievers and establish God's kingdom on earth. Then the Antichrist (*dajjal*) will work new mischief, but be destroyed by Jesus, who appears as precursor of the last judgment. Sunnite theologians have not all been at one in expecting a Mahdí as well as Jesus, but this is the view generally current in recent times; and Sunnites and Shí'ites are agreed that the Mahdí will destroy the external foes of Islam, *i.e.*, all non-Mohammedan powers. Theologians have tried by artificial interpretation of Koran and Sunna to fix when and how the Mahdí is to appear, and have concluded that he must be looked for at the close of a century. Of this widespread belief Mohammed Ahmed, the Sudanese Mahdí, availed himself in coming forward in the year 1300 of the Flight (1882-83). Theological opinion is so unsettled as to all the details of the Mahdí's work that, according to trustworthy information, his death has not seriously impaired the impression produced by his victories. In Mecca, for example, in 1885 it was commonly held to be conceivable that the Sudanese fighting in his name might destroy England and the Western powers; and it is possible that the belief in this latest Mahdí has still an important part to play in the Eastern question. (A. MÜ.)

SUNSTROKE (*Heatstroke*, *Insolation*, *Coup de Soleil*, *Thermic Fever*), a term applied to the effects produced upon the central nervous system, and through it upon other organs of the body, by exposure to the sun or to overheated air. Although most frequently observed in tropical regions, this disease occurs also in temperate climates during hot weather. A moist condition of the atmosphere, which interferes with cooling of the overheated body, greatly increases the liability to suffer from this ailment.

Sunstroke has been chiefly observed and investigated as occurring among soldiers in India, where formerly, both in active service and in the routine of ordinary duty, cases of this disease constituted a considerable item of sickness and mortality. The increased attention now paid by military authorities to the personal health and comfort of the soldier, particularly as regards barrack accommodation and dress, together with the care taken in adjusting the time and mode of movement of troops, has done much to lessen the mortality from this cause. It would appear that, while any one exposed to the influence of strong solar heat may suffer from the symptoms of sunstroke, there are certain conditions which greatly predispose to it in the case of individuals. Causes calculated to depress the health, such as previous disease, particularly affections of the nervous system,—anxiety, worry, or overwork, irregularities in food, and in a marked degree intemperance—have a powerful predisposing influence, while personal uncleanliness, which prevents among other things the healthy action of the skin, the wearing of tight garments, which impede the functions alike of heart and lungs, and living in overcrowded and insanitary dwellings have an equally hurtful tendency.

While attacks of sunstroke are frequently precipitated by exposure, especially during fatigue, to the direct rays of the sun, in a large number of instances they come on under other circumstances. Cases are of not unfrequent occurrence among soldiers in hot climates when there is overcrowding or bad ventilation in their barracks, and sometimes several will be attacked in the course of a single night. The same remark applies to similar conditions existing on shipboard. Further, persons whose occupation exposes them to excessive heat, such as stokers, laundry workers, &c., are apt to suffer, particularly in hot seasons. In the tropics Europeans, especially those who have recently arrived, are more readily affected than natives. But natives are not exempt.

The symptoms of heatstroke, which obviously depend upon the disorganization of the normal heat-regulating mechanism, as well as of the functions of circulation and respiration (see PATHOLOGY, vol. xviii. p. 391), vary in their intensity and likewise to some extent in their form. Three chief types of the disease are usually described.

(1) *Heat Syncope*.—In this form the symptoms are those of exhaustion, with a tendency towards fainting or its actual occurrence. A fully developed attack of this description is usually preceded by sickness, giddiness, some amount of mental excitement followed by drowsiness, and then the passage into the syncopal condition, in which there are pallor and coldness of the skin, a weak, quick, and intermittent pulse, and gasping or sighing respiration. The pupils are often contracted. Death may quickly occur; but if timely treatment is available recovery may take place.

(2) *Heat Apoplexy or Asphyxia*.—In this variety the attack, whether preceded or not by the premonitory symptoms already mentioned, is usually sudden, and occurs in the form of an apoplectic seizure, with great vascular engorgement, as seen in the flushed face, congested eyes, quick full pulse, and stertorous breathing. There is usually insensibility, and convulsions are not unfrequent. Death is often very sudden. This form, however, is also amenable to treatment.

(3) *Ardent Thermic Fever*.—This variety is characterized chiefly by the excessive development of fever (hyperpyrexia), the temperature of the body rising at such times to 108° to 110° Fahr. or more. Accompanying this are the other symptoms of high febrile disturbance, such as great thirst, quick full pulse, pains throughout the body, headache, nausea, and vomiting, together with respiratory embarrassment. After the attack has lasted for a variable period, often one or two days, death may ensue from collapse or from the case assuming the apoplectic form already described. But here too treatment may be successful if it is promptly applied.

[1] See on Báb and Bábism, Mirza Kazem Beg, in *Journ. Asiatique*, ser. 6, vols. vii.-viii.; Gobineau, *op. cit.*, where there is a translation of Báb's new Koran; Von Kremer, *op. cit.*, p. 202 *sq.*

[2] See Garcin de Tassy, *L'Islamisme*, 3d ed. (1874), p. 298, and Rehatsek, *ut sup.*

[3] Compare especially Snouck Hurgronje, "Der Mahdi," in *Revue Coloniale Internationale*, 1885, an article based on wide reading and personal observations at Jeddah and Mecca.

Besides these, other varieties depending on the prominence of certain symptoms are occasionally met with. The chief changes in the body after death from heatstroke are those of anæmia of the brain and congestion of the lungs, together with softness of the heart and of the muscular tissues generally. The blood is dark and fluid and the blood corpuscles are somewhat altered in shape. Attacks of sunstroke are apt to leave traces of their effects upon the constitution, especially upon the nervous system. A liability to severe headache, which in many cases would seem to depend upon a condition of chronic meningitis, epileptic fits, mental irritability, and alterations in the disposition are among the more important. It is often observed that heat in any form is ever afterwards ill borne, while there also appears to be an abnormal susceptibility to the action of stimulants. The mortality from sunstroke is estimated at from 40 to 50 per cent.

Treatment.—In respect of this disease means should be adopted to prevent attacks in the case of those who must necessarily be exposed to the sun. These consist in the wearing of loose clothing, with the exception of the headdress, which ought to be worn close to the head, in due attention to the function of the skin, and in the avoidance of alcoholic and other excesses. Cold water may be drunk in small quantities at frequent intervals. Sleeping in the open air in very hot seasons is recommended. The treatment of a patient suffering from an attack necessarily depends upon the form it has assumed. In all cases he should if possible be at once removed into a shaded or cool place. Where the symptoms are mostly those of syncope and there is a tendency to death from heart failure, rest in the recumbent position, the use of diffusible stimulants, such as ammonia or ether, &c., together with friction or warmth applied to the extremities, are the means to be adopted. Where, on the other hand, the symptoms are those of apoplexy or of hyperpyrexia, by far the most successful results are obtained by the use of cold (the cold affusion, rubbing the surface with ice, enemata of ice-cold water). The effect is a marked lowering of the temperature, while at the same time a stimulus is given to the respiratory function. Mustard or turpentine applied to the nape of the neck or chest is a useful adjuvant. Should the temperature be lowered in this way but unconsciousness still persist, removal of the hair and blistering the scalp are recommended. The subsequent treatment will depend upon the nature of the resulting symptoms, but change to a cool climate is often followed by marked benefit. (J. O. A.)

SUPERIOR, LAKE. See LAKE and ST LAWRENCE.

SURABAYA. See JAVA, vol. xiii. p. 605 *sq.* The population in 1880 was 122,234.

SURAKARTA, or SOLO. See JAVA, vol. xiii. pp. 601, 606 *sq.* Its population was 124,041 in 1880.

SURAT, a district of British India, in the Guzerat division of Bombay presidency, lying between 20° 15′ and 21° 28′ N. lat. and 72° 38′ and 73° 30′ E. long. It has an area of 1662 square miles, and is bounded on the N. by Broach district and the native state of Baroda, on the E. by the states of Rájpipla, the Gáikwár Bánsda, and Dharampur, on the S. by Thána district and the Portuguese territory of Daman, and on the W. by the Arabian Sea. It has a coast-line of 80 miles, consisting of a barren stretch of sand drift and salt marsh; behind that is a rich highly cultivated plain, nearly 60 miles in breadth at the embouchure of the Tápti, but narrowing to only 15 miles in the southern part; and on the north-east are the wild hills and jungle of the Dangs. The only important rivers are the Tápti and the Kim, the former of which is ordinarily navigable for native craft of from 18 to 36 tons. The district contains a large number of tanks for irrigation, and a canal is projected from the Tápti with head works at Kamlápur, 35 miles from Surat. The fauna of the district consists of a few tigers, stragglers from the jungles of Bánsda and Dharampur, besides leopards, bears, wild boars, wolves, hyænas, spotted deer, and antelopes. The climate of Surat varies with the distance from the sea. Near the coast, under the influence of the sea-breeze, an equable temperature prevails, but 8 to 11 miles inland the breeze ceases to blow. The coast also possesses a much lighter rainfall than the interior, the annual average ranging from 30 inches in Olpad to 72 in Chikhli, while at Surat city the average is 46 inches. The Bombay, Baroda, and Central India Railway runs through the district from north to south. A magnificent iron-girder bridge crosses the Tapti at Surat city.

The census of 1881 returned the population of Surat at 614,198 (306,015 males, 308,183 females), of whom Hindus numbered 415,031, Mohammedans 55,547, Parsis 12,593, and aboriginals 118,664. There are only two towns in the district with a population exceeding 5000,—namely, SURAT (*q.v.*) and Bulsar (13,229). The cultivated area in 1884-85 was returned at 726,583 acres, and the area available for cultivation at 81,663. The total area of crops in 1884-85 was 550,233 acres, including 66,096 twice cropped. Rice occupied 103,972 acres, wheat 38,617, and *joar* 108,644; cotton is also largely cultivated, and its culture is greatly increasing. Grain, cotton, timber, oil, sugar and molasses, and piece goods are the chief articles of export. Almost the whole female population is engaged in spinning cotton thread, and the weaving of cotton cloth in hand looms is carried on in the chief towns; silk is also manufactured in considerable quantities, as well as brocades and embroidery. In 1884-85 the revenue of the district amounted to £378,061, of which the land-tax contributed £268,644. Surat was one of the earliest parts of India brought into close relations with European countries, and its history merges almost entirely into that of its capital, long the greatest maritime city of the peninsula. By an arrangement made in 1799 the English were placed in possession of Surat city and the town of Rander; subsequent cessions under the treaties of Bassein (1802) and Poona (1817), together with the lapse of the Mandvi state in 1839, brought the district into its present shape. Since the introduction of British rule the district has remained comparatively tranquil; and even during the period of the mutiny peace was not disturbed, owing in a great measure to the steadfast loyalty of its leading Mohammedan families.

SURAT, capital and administrative headquarters of the above district, is situated in 21° 9′ 30″ N. lat. and 72° 54′ 15″ E. long., on the southern bank of the Tápti, distant from the sea 14 miles by water and 10 by land. Its origin appears to be comparatively modern, tradition assigning the foundation of the town to the beginning of the 16th century. As early as 1514 it was described by the Portuguese traveller Barbosa as a "very important seaport." During the reigns of Akbar, Jahángír, and Sháh Jahán it rose to be the chief commercial city of India. From 1573 to 1612 the Portuguese were undisputed masters of the Surat seas and part of the seaboard. But shortly after 1612 the city of Surat became the seat of a presidency under the English East India Company, and the Dutch also had made it their principal factory in India. During the 18th century it probably ranked as the most populous city of India, its population being at one time estimated as high as 800,000; but with the transfer of its trade to Bombay the numbers rapidly fell off, until in 1847 its inhabitants numbered only 80,000. Thenceforward the city began to retrieve its position, and in 1881 its population numbered 107,154 (54,524 males and 52,630 females).

SURBITON, a suburb of Kingston in Surrey, England, is finely situated on the river Thames, 12 miles south-west of London by the London and South-Western Railway. It consists chiefly of villa residences embosomed in woods and gardens. Along the river an esplanade has been constructed, forming a pleasant promenade. Surbiton is the headquarters of the Kingston Rowing Club and the Thames Sailing Club. The recreation ground, in connexion with which there is a reading-room and library, is much frequented for athletic meetings and bicycle races. In the town there is a cottage hospital. The population of the urban sanitary district (area, 1000 acres) in 1871 was 7642, and in 1881 it was 9406.

SURETY, in law, is the party liable under a contract of GUARANTEE (*q.v.*). In criminal practice sureties bound by RECOGNIZANCE (*q.v.*) are a means of obtaining compliance with the order of a court of justice, whether to keep the peace or otherwise.

SURFACE, CONGRUENCE, COMPLEX In the article CURVE the subject was treated from an historical point of view for the purpose of showing how the leading ideas of the theory were successively arrived at These leading ideas apply to surfaces, but the ideas peculiar to surfaces are scarcely of the like fundamental nature, being rather developments of the former set in their application to a more advanced portion of geometry, there is consequently less occasion for the historical mode of treatment Curves in space were briefly considered in the same article, and they will not be discussed here, but it is proper to refer to them in connexion with the other notions of solid geometry In plane geometry the elementary figures are the point and the line, and we then have the curve, which may be regarded as a singly infinite system of points, and also as a singly infinite system of lines In solid geometry the elementary figures are the point, the line, and the plane, we have, moreover, first, that which under one aspect is the curve and under another aspect the developable (or torse), and which may be regarded as a singly infinite system of points, of lines, or of planes, and secondly, the surface, which may be regarded as a doubly infinite system of points or of planes, and also as a special triply infinite system of lines (The tangent lines of a surface are a special complex) As distinct particular cases of the first figure we have the plane curve and the cone, and as a particular case of the second figure the ruled surface, regulus, or singly infinite system of lines, we have, besides, the congruence or doubly infinite system of lines and the complex or triply infinite system of lines And thus crowds of theories arise which have hardly any analogues in plane geometry, the relation of a curve to the various surfaces which can be drawn through it, and that of a surface to the various curves which can be drawn upon it, are different in kind from those which in plane geometry most nearly correspond to them,—the relation of a system of points to the different curves through them and that of a curve to the systems of points upon it In particular, there is nothing in plane geometry to correspond to the theory of the curves of curvature of a surface Again, to the single theorem of plane geometry, that a line is the shortest distance between two points, there correspond in solid geometry two extensive and difficult theories,—that of the geodesic lines on a surface and that of the minimal surface, or surface of minimum area, for a given boundary And it would be easy to say more in illustration of the great extent and complexity of the subject.

Surfaces in General, Torses, &c

1 A surface may be regarded as the locus of a doubly infinite system of points,—that is, the locus of the system of points determined by a single equation $U=(*\between x, y, z, 1)^n$, $=0$, between the Cartesian coordinates (to fix the ideas, say rectangular coordinates) x, y, z, or, if we please, by a single homogeneous relation $U=(*\between x,y,z,w)^n, =0$, between the quadriplanar coordinates x, y, z, w The degree n of the equation is the order of the surface, and this definition of the order agrees with the geometrical one, that the order of the surface is equal to the number of the intersections of the surface by an arbitrary line Starting from the foregoing point definition of the surface, we might develop the notions of the tangent line and the tangent plane, but it will be more convenient to consider the surface *ab initio* from the more general point of view in its relation to the point, the line, and the plane

2 Mention has been made of the plane curve and the cone, it is proper to recall that the *order* of a plane curve is equal to the number of its intersections by an arbitrary line (in the plane of the curve), and that its *class* is equal to the number of tangents to the curve which pass through an arbitrary point (in the plane of the curve) The cone is a figure correlative to the plane curve corresponding to the plane of the curve we have the vertex of the cone, to its tangents the generating lines of the cone, and to its points the tangent planes of the cone But from a different point of view we may consider the generating lines of the cone as corresponding to the points of the curve and its tangent planes as corresponding to the tangents of the curve From this point of view we define the order of the cone as equal to the number of its intersections (generating lines) by an arbitrary plane through the vertex, and its class as equal to the number of the tangent planes which pass through an arbitrary line through the vertex And in the same way that a plane curve has singularities (singular points and singular tangents) so a cone has singularities (singular generating lines and singular tangent planes)

3 Consider now a surface in connexion with an arbitrary line The line meets the surface in a certain number of points, and, as already mentioned, the *order* of the surface is equal to the number of these intersections We have through the line a certain number of tangent planes of the surface, and the *class* of the surface is equal to the number of these tangent planes

But, further, through the line imagine a plane, this meets the surface in a curve the order of which is equal (as is at once seen) to the order of the surface Again, on the line imagine a point, this is the vertex of a cone circumscribing the surface, and the class of this cone is equal (as is at once seen) to the class of the surface The tangent lines of the surface which lie in the plane are nothing else than the tangents of the plane section, and thus form a singly infinite series of lines, similarly, the tangent lines of the surface which pass through the point are nothing else than the generating lines of the circumscribed cone, and thus form a singly infinite series of lines But, if we consider those tangent lines of the surface which are at once in the plane and through the point, we see that they are finite in number, and we define the *rank* of a surface as equal to the number of tangent lines which lie in a given plane and pass through a given point in that plane It at once follows that the class of the plane section and the order of the circumscribed cone are each equal to the rank of the surface, and are thus equal to each other It may be noticed that for a general surface $(*\between x, y, z, w)^n$, $=0$, of order n without point singularities the rank is $a, = n(n-1)$, and the class is $n', = n(n-1)^2$, this implies (what is in fact the case) that the circumscribed cone has line singularities, for otherwise its class, that is the class of the surface, would be $a(a-1)$, which is not $= n(n-1)^2$

4 In the last preceding number the notions of the tangent line and the tangent plane have been assumed as known, but they require to be further explained in reference to the original point definition of the surface Speaking generally, we may say that the points of the surface consecutive to a given point on it lie in a plane which is the tangent plane at the given point, and conversely the given point is the point of contact of this tangent plane, and that any line through the point of contact and in the tangent plane is a tangent line touching the surface at the point of contact Hence we see at once that the tangent line is any line meeting the surface in two consecutive points, or—what is the same thing—a line meeting the surface in the point of contact counting as two intersections and in $\overline{n-2}$ other points But, from the foregoing notion of the tangent plane as a plane containing the point of contact and the consecutive points of the surface, the passage to the true definition of the tangent plane is not equally obvious A plane in general meets the surface of the order n in a curve of that order without double points, but the plane may be such that the curve has a

double point, and when this is so the plane is a tangent plane having the double point for its point of contact The double point is either an acnode (isolated point), then the surface at the point in question is convex towards (that is, concave away from) the tangent plane, or else it is a crunode, and the surface at the point in question is then concavo-convex, that is, it has its two curvatures in opposite senses (see *infra*, No 16) Observe that in either case any line whatever in the plane and through the point meets the surface in the points in which it meets the plane curve, namely, in the point of contact, which *qua* double point counts as two intersections, and in $\overline{n-2}$ other points, that is, we have the preceding definition of the tangent line

5 The complete enumeration and discussion of the singularities of a surface is a question of extreme difficulty which has not yet been solved [1] A plane curve has point singularities and line singularities, corresponding to these we have for the surface isolated point singularities and isolated plane singularities, but there are besides continuous singularities applying to curves on or torses circumscribed to the surface, and it is among these that we have the non-special singularities which play the most important part in the theory Thus the plane curve represented by the general equation $(*\between x, y, z)^n=0$, of any given order n, has the non-special line singularities of inflexions and double tangents, corresponding to this the surface represented by the general equation $(*\between x, y, z, w)^n=0$, of any given order n, has, not the isolated plane singularities, but the continuous singularities of the spinode curve or torse and the node-couple curve or torse A plane may meet the surface in a curve having (1) a cusp (spinode) or (2) a pair of double points, in each case there is a singly infinite system of such singular tangent planes, and the locus of the points of contact is the curve, the envelope of the tangent planes the torse The reciprocal singularities to these are the nodal curve and the cuspidal curve. the surface may intersect or touch itself along a curve in such wise that, cutting the surface by an arbitrary plane, the curve of intersection has at each intersection of the plane with the curve on the surface (1) a double point (node) or (2) a cusp Observe that these are singularities not occurring in the surface represented by the general equation $(*\between x, y, z, w)^n=0$ of any order, observe further that in the case of both or either of these singularities the definition of the tangent plane must be modified A tangent plane is a plane such that there is in the plane section a double point in addition to the nodes or cusps at the intersections with the singular lines on the surface

6 As regards isolated singularities, it will be sufficient to mention the point singularity of the conical point (or cnicnode) and the corresponding plane singularity of the conic of contact (or cnictrope) In the former case we have a point such that the consecutive points, instead of lying in a tangent plane, lie on a quadric cone, having the point for its vertex, in the latter case we have a plane touching the surface along a conic, that is, the complete intersection of the surface by the plane is made up of the conic taken twice and of a residual curve of the order $n-4$

7 We may, in the general theory of surfaces, consider either a surface and its reciprocal surface, the reciprocal surface being taken to be the surface enveloped by the polar planes (in regard to a given quadric surface) of the points of the original surface, or—what is better—we may consider a given surface in reference to the reciprocal relations of its order, rank, class, and singularities In either case we have a series of unaccented letters and a corresponding series of accented letters, and the relations between them are such that we may in any equation interchange the accented and the unaccented letters, in some cases an unaccented letter may be equal to the corresponding accented letter Thus, let n, n' be as before the order and the class of the surface, but, instead of immediately defining the rank, let a be used to denote the class of the plane section and a' the order of the circumscribed cone, also let S, S' be numbers referring to the singularities The form of the relations is $a=a'(=\text{rank of surface})$, $a'=n(n-1)-S$, $n'=n(n-1)^2-S$, $a=n'(n'-1)-S'$, $n=n'(n'-1)^2-S'$ In these last equations S, S' are merely written down to denote proper corresponding combinations of the several numbers referring to the singularities collectively denoted by S, S' respectively The theory, as already mentioned, is a complex and difficult one, and it is not the intention to further develop it here

8 A developable or torse corresponds to a curve in space in the same manner as a cone corresponds to a plane curve although capable of representation by an equation $U=(*\between x, y, z, w,)^n,=0$, and so of coming under the foregoing point definition of a surface, it is an entirely distinct geometrical conception We may indeed, *qua* surface, regard it as a surface characterized by the property that each of its tangent planes touches it, not at a single point, but along a line, this is equivalent to saying that it is the envelope, not of a doubly infinite series of planes, as is a proper surface, but of a singly infinite system of planes But it is perhaps easier to regard it as the locus of a singly infinite system of lines, each line meeting the consecutive line, or, what is the same thing, the lines being tangent lines of a curve in space The tangent plane is then the plane through two consecutive lines, or, what is the same thing, an osculating plane of the curve, whence also the tangent plane intersects the surface in the generating line counting twice, and in a residual curve of the order $n-2$ The curve is said to be the edge of regression of the developable, and it is a cuspidal curve thereof, that is to say, any plane section of the developable has at each point of intersection with the edge of regression a cusp A sheet of paper bent in any manner without crumpling gives a developable, but we cannot with a single sheet of paper properly exhibit the form in the neighbourhood of the edge of regression we need two sheets connected along a plane curve, which, when the paper is bent, becomes the edge of regression and appears as a cuspidal curve on the surface

It may be mentioned that the condition which must be satisfied in order that the equation $U=0$ shall represent a developable is $H(U)=0$, that is, the Hessian or functional determinant formed with the second differential coefficients of U must vanish in virtue of the equation $U=0$, or—what is the same thing—$H(U)$ must contain U as a factor If in Cartesian coordinates the equation is taken in the form $z-f(x, y)=0$, then the condition is $rt-s^2=0$ identically, where r, s, t denote as usual the second differential coefficients of z in regard to x, y respectively

9 A ruled surface or regulus is the locus of a singly infinite system of lines, where the consecutive lines do not intersect, this is a true surface, for there is a doubly infinite series of tangent planes,—in fact any plane through any one of the lines is a tangent plane of the surface, touching it at a point on the line, and in such wise that, as the tangent plane turns about the line, the point of contact moves along the line The complete intersection of the surface by the tangent plane is made up of the line counting once and of a residual curve of the order $n-1$ A quadric surface is a regulus in a twofold manner, for

[1] In a plane curve the only singularities which need to be considered are those that present themselves in Plucker's equations, for every higher singularity whatever is equivalent to a certain number of nodes, cusps, inflexions, and double tangents As regards a surface, no such reduction of the higher singularities has as yet been made

there are on the surface two systems of lines each of which is a regulus A cubic surface may be a regulus (see No 11 *infra*)

Surfaces of the Orders 2, 3, and 4

10 A surface of the second order or a quadric surface is a surface such that every line meets it in two points, or—what comes to the same thing—such that every plane section thereof is a conic or quadric curve Such surfaces have been studied from every point of view The only singular forms are when there is (1) a conical point (cnicnode), when the surface is a cone of the second order or quadricone, (2) a conic of contact (cnictrope), when the surface is this conic, from a different point of view it is a *surface aplatie* or flattened surface Excluding these degenerate forms, the surface is of the order, rank, and class each $=2$, and it has no singularities Distinguishing the forms according to *reality*, we have the ellipsoid, the hyperboloid of two sheets, the hyperboloid of one sheet, the elliptic paraboloid, and the hyperbolic paraboloid (see GEOMETRY, ANALYTICAL) A particular case of the ellipsoid is the sphere, in abstract geometry this is a quadric surface passing through a given quadric curve, the circle at infinity The tangent plane of a quadric surface meets it in a quadric curve having a node, that is, in a pair of lines, hence there are on the surface two singly infinite sets of lines Two lines of the same set do not meet, but each line of the one set meets each line of the other set, the surface is thus a regulus in a twofold manner The lines are real for the hyperboloid of one sheet and for the hyperbolic paraboloid, for the other forms of surface they are imaginary

11 We have next the surface of the third order or cubic surface, which has also been very completely studied Such a surface may have isolated point singularities (cnicnodes or points of higher singularity), or it may have a nodal line, we have thus $21+2,=23$ cases In the general case of a surface without any singularities, the order, rank, and class are $=3$, 6, 12 respectively The surface has upon it 27 lines, lying by threes in 45 planes, which are triple tangent planes Observe that the tangent plane is a plane meeting the surface in a curve having a node For a surface of any given order n there will be a certain number of planes each meeting the surface in a curve with 3 nodes, that is, triple tangent planes, and, in the particular case where $n=3$, the cubic curve with 3 nodes is of course a set of 3 lines, it is found that the number of triple tangent planes is, as just mentioned, $=45$ This would give 135 lines, but through each line we have 5 such planes, and the number of lines is thus $=27$ The theory of the 27 lines is an extensive and interesting one, in particular, it may be noticed that we can, in thirty-six ways, select a system of 6×6 lines, or "double sixer," such that no 2 lines of the same set intersect each other, but that each line of the one set intersects each line of the other set

A cubic surface having a nodal line is a ruled surface or regulus, in fact any plane through the nodal line meets the surface in this line counting twice and in a residual line, and there is thus on the surface a singly infinite set of lines There are two forms, but the distinction between them need not be referred to here

12 As regards quartic surfaces, only particular forms have been much studied A quartic surface can have at most 16 conical points (cnicnodes), an instance of such a surface is Fresnel's wave surface, which has 4 real cnicnodes in one of the principal planes, 4×2 imaginary ones in the other two principal planes, and 4 imaginary ones at infinity,—in all 16 cnicnodes, the same surface has also 4 real + 12 imaginary planes each touching the surface along a circle (cnictropes),—in all 16 cnictropes It was easy by a mere homographic transformation to pass to the more general surface called the tetrahedroid, but this was itself only a particular form of the general surface with 16 cnicnodes and 16 cnictropes first studied by Kummer Quartic surfaces with a smaller number of cnicnodes have also been considered

Another very important form is the quartic surface having a nodal conic, the nodal conic may be the circle at infinity, and we have then the so-called anallagmatic surface, otherwise the cyclide (which includes the particular form called Dupin's cyclide) These correspond to the bicircular quartic curve of plane geometry Other forms of quartic surface might be referred to

Congruences and Complexes

13 A congruence is a doubly infinite system of lines. A line depends on four parameters and can therefore be determined so as to satisfy four conditions, if only two conditions are imposed on the line we have a doubly infinite system of lines or a congruence For instance, the lines meeting each of two given lines form a congruence It is hardly necessary to remark that, imposing on the line one more condition, we have a ruled surface or regulus; thus we can in an infinity of ways separate the congruence into a singly infinite system of reguli or of torses (see *infra*, No 16)

Considering in connexion with the congruence two arbitrary lines, there will be in the congruence a determinate number of lines which meet each of these two lines, and the number of lines thus meeting the two lines is said to be the *order-class* of the congruence If the two arbitrary lines are taken to intersect each other, the congruence lines which meet each of the two lines separate themselves into two sets,—those which lie in the plane of the two lines and those which pass through their intersection There will be in the former set a determinate number of congruence lines which is the *order* of the congruence, and in the latter set a determinate number of congruence lines which is the *class* of the congruence In other words, the order of the congruence is equal to the number of congruence lines lying in an arbitrary plane, and its class to the number of congruence lines passing through an arbitrary point

The following systems of lines form each of them a congruence —(A) lines meeting each of two given curves; (B) lines meeting a given curve twice, (C) lines meeting a given curve and touching a given surface, (D) lines touching each of two given surfaces, (E) lines touching a given surface twice, or, say, the bitangents of a given surface

The last case is the most general one, and conversely for a given congruence there will be in general a surface having the congruence lines for bitangents This surface is said to be the *focal surface* of the congruence, the general surface with 16 cnicnodes first presented itself in this manner as the focal surface of a congruence But the focal surface may degenerate into the forms belonging to the other cases A, B, C, D

14 A complex is a triply infinite system of lines,—for instance, the tangent lines of a surface Considering an arbitrary point in connexion with the complex, the complex lines which pass through the point form a cone; considering a plane in connexion with it, the complex lines which lie in the plane envelope a curve It is easy to see that the class of the curve is equal to the order of the cone; in fact each of these numbers is equal to the number of complex lines which lie in an arbitrary plane and pass through an arbitrary point of that plane; and we then say *order* of complex = order of curve, *rank* of complex = class of curve = order of cone, *class* of complex = class of cone It is to be observed that, while

for a congruence there is in general a surface having the congruence lines for bitangents, for a complex there is not in general any surface having the complex lines for tangents, the tangent lines of a surface are thus only a special form of complex The theory of complexes first presented itself in the researches of Malus on systems of rays of light in connexion with double refraction

15 The analytical theory as well of congruences as of complexes is most easily carried out by means of the six coordinates of a line, viz, there are coordinates (a, b, c, f, g, h) connected by the equation $af + bg + ch = 0$, and therefore such that the ratios a b c f g h constitute a system of four arbitrary parameters We have thus a congruence of the order n represented by a single homogeneous equation of that order $(*\between a, b, c, f, g, h)^n = 0$ between the six coordinates, two such relations determine a congruence But we have in regard to congruences the same difficulty as that which presents itself in regard to curves in space it is not every congruence which can be represented completely and precisely by *two* such equations

The linear equation $(*\between a, b, c, f, g, h) = 0$ represents a congruence of the first order or linear congruence, such congruences are interesting both in geometry and in connexion with the theory of forces acting on a rigid body

Curves of Curvature, Asymptotic Lines

16 The normals of a surface form a congruence In any congruence the lines consecutive to a given congruence line do not in general meet this line, but there is a determinate number of consecutive lines which do meet it, or, attending for the moment to only one of these, say the congruence line is met by a consecutive congruence line In particular, each normal is met by a consecutive normal, this again is met by a consecutive normal, and so on That is, we have a singly infinite system of normals each meeting the consecutive normal, and so forming a torse, starting from different normals successively, we obtain a singly infinite system of such torses But each normal is in fact met by two consecutive normals, and, using in the construction first the one and then the other of these, we obtain two singly infinite systems of torses each intersecting the given surface at right angles In other words, if in place of the normal we consider the point on the surface, we obtain on the surface two singly infinite systems of curves such that for any curve of either system the normals at consecutive points intersect each other, moreover, for each normal the torses of the two systems intersect each other at right angles, and therefore for each point of the surface the curves of the two systems intersect each other at right angles The two systems of curves are said to be the curves of curvature of the surface

The normal is met by the two consecutive normals in two points which are the centres of curvature for the point on the surface, these lie either on the same side of the point or on opposite sides, and the surface has at the point in question like curvatures or opposite curvatures in the two cases respectively (see *supra*, No 4)

17 In immediate connexion with the curves of curvature we have the so-called asymptotic curves (Haupt-tangenten-linien) The tangent plane at a point of the surface cuts the surface in a curve having at that point a node Thus we have at the point of the surface two directions of passage to a consecutive point, or, say, two elements of arc, and, passing along one of these to the consecutive point, and thence to a consecutive point, and so on, we obtain on the surface a curve Starting successively from different points of the surface we thus obtain a singly infinite system of curves, or, using first one and then the other of the two directions, we obtain two singly infinite systems of curves, which are the curves above referred to The two curves at any point are equally inclined to the two curves of curvature at that point, or—what is the same thing—the supplementary angles formed by the two asymptotic lines are bisected by the two curves of curvature In the case of a quadric surface the asymptotic curves are the two systems of lines on the surface

Geodesic Lines

18 A geodesic line (or curve) is a shortest curve on a surface, more accurately, the element of arc between two consecutive points of a geodesic line is a shortest arc on the surface We are thus led to the fundamental property that at each point of the curve the osculating plane of the curve passes through the normal of the surface, in other words, any two consecutive arcs PP', $P'P''$ are *in plano* with the normal at P' Starting from a given point P on the surface, we have a singly infinite system of geodesics proceeding along the surface in the direction of the several tangent lines at the point P, and, if the direction PP' is given, the property gives a construction by successive elements of arc for the required geodesic line

Considering the geodesic lines which proceed from a given point P of the surface, any particular geodesic line is or is not again intersected by the consecutive generating line, if it is thus intersected, the generating line is a shortest line on the surface up to, but not beyond, the point at which it is first intersected by the consecutive generating line, if it is not intersected, it continues a shortest line for the whole course

In the analytical theory both of geodesic lines and of the curves of curvature, and in other parts of the theory of surfaces, it is very convenient to consider the rectangular coordinates x, y, z of a point of the surface as given functions of two independent parameters p, q, the form of these functions of course determines the surface, since by the elimination of p, q from the three equations we obtain the equation in the coordinates x, y, z We have for the geodesic lines a differential equation of the second order between p and q, the general solution contains two arbitrary constants, and is thus capable of representing the geodesic line which can be drawn from a given point in a given direction on the surface In the case of a quadric surface the solution involves hyperelliptic integrals of the first kind, depending on the square root of a sextic function

Curvilinear Coordinates

19 The expressions of the coordinates x, y, z in terms of p, q may contain a parameter r, and, if this is regarded as a given constant, these expressions will as before refer to a point on a given surface But, if p, q, r are regarded as three independent parameters, x, y, z will be the coordinates of a point in space, determined by means of the three parameters p, q, r, these parameters are said to be the curvilinear coordinates, or (in a generalized sense of the term) simply the coordinates of the point We arrive otherwise at the notion by taking p, q, r each as a given function of x, y, z, say we have $p = f_1(x, y, z)$, $q = f_2(x, y, z)$, $r = f_3(x, y, z)$, which equations of course lead to expressions for p, q, r each as a function of x, y, z The first equation determines a singly infinite set of surfaces for any given value of p we have a surface, and similarly the second and third equations determine each a singly infinite set of surfaces If, to fix the ideas, f_1, f_2, f_3 are taken to denote each a rational and integral function of x, y, z, then two surfaces of the same set will not intersect each other, and through a given point of space there will pass one surface of each set, that is, the point will be determined as a point of intersection of three surfaces belonging to the three sets respectively, moreover, the whole of space will be divided by the three sets of surfaces into a triply infinite system of elements, each of them being a parallelepiped

Orthotomic Surfaces, Parallel Surfaces

20 The three sets of surfaces may be such that the three surfaces through any point of space whatever intersect each other at right angles, and they are in this case said to be orthotomic The term curvilinear coordinates was almost appropriated by Lame, to whom this theory is chiefly due, to the case in question assuming that the equations $p=f_1(x,y,z)$, $q=f_2(x,y,z)$, $r=f_3(x,y,z)$ refer to a system of orthotomic surfaces, we have in the restricted sense p, q, r as the curvilinear coordinates of the point

An interesting special case is that of confocal quadric surfaces The general equation of a surface confocal with the ellipsoid $\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=1$ is $\frac{x^2}{a^2+\theta}+\frac{y^2}{b^2+\theta}+\frac{z^2}{c^2+\theta}=1$, and, if in this equation we consider x, y, z as given, we have for θ a cubic equation with three real roots p, q, r, and thus we have through the point three real surfaces, one an ellipsoid, one a hyperboloid of one sheet, and one a hyperboloid of two sheets

21 The theory is connected with that of curves of curvature by Dupin's theorem Thus in any system of orthotomic surfaces each surface of any one of the three sets is intersected by the surfaces of the other two sets in its curves of curvature

22 No one of the three sets of surfaces is altogether arbitrary in the equation $p=f_1(x,y,z)$, p is not an arbitrary function of x, y, z, but it must satisfy a certain partial differential equation of the third order Assuming that p has this value, we have $q=f_2(x,y,z)$ and $r=f_3(x,y,z)$ determinate functions of x, y, z such that the three sets of surfaces form an orthotomic system

23 Starting from a given surface, it has been seen (No 16) that the normals along the curves of curvature form two systems of torses intersecting each other, and also the given surface, at right angles But there are, intersecting the two systems of torses at right angles, not only the given surface, but a singly infinite system of surfaces If at each point of the given surface we measure off along the normal one and the same distance at pleasure, then the locus of the points thus obtained is a surface cutting all the normals of the given surface at right angles, or, in other words, having the same normals as the given surface, and it is therefore a parallel surface to the given surface Hence the singly infinite system of parallel surfaces and the two singly infinite systems of torses form together a set of orthotomic surfaces

The Minimal Surface

24 This is the surface of minimum area—more accurately, a surface such that, for any indefinitely small closed curve which can be drawn on it round any point, the area of the surface is less than it is for any other surface whatever through the closed curve It at once follows that the surface at every point is concavo-convex, for, if at any point this was not the case, we could, by cutting the surface by a plane, describe round the point an indefinitely small closed plane curve, and the plane area within the closed curve would then be less than the area of the element of surface within the same curve The condition leads to a partial differential equation of the second order for the determination of the minimal surface considering z as a function of x, y, and writing as usual p, q, r, s, t for the first and second differential coefficients of z in regard to x, y respectively, the equation (as first shown by Lagrange) is $(1+q^2)r-2pqs+(1+p^2)t=0$, or, as this may also be written, $\frac{d}{dy}\frac{q}{\sqrt{1+p^2+q^2}}+\frac{d}{dx}\frac{p}{\sqrt{1+p^2+q^2}}=0$ The general integral contains of course arbitrary functions, and, if we imagine these so determined that the surface may pass through a given closed curve, and if, moreover, there is but one minimal surface passing through that curve, we have the solution of the problem of finding the surface of minimum area within the same curve The surface continued beyond the closed curve is a minimal surface, but it is not of necessity or in general a surface of minimum area for an arbitrary bounding curve not wholly included within the given closed curve It is hardly necessary to remark that the plane is a minimal surface, and that, if the given closed curve is a plane curve, the plane is the proper solution, that is, the plane area within the given closed curve is less than the area for any other surface through the same curve The given closed curve is not of necessity a single curve it may be, for instance, a skew polygon of four or more sides

The partial differential equation was dealt with in a very remarkable manner by Riemann From the second form given above it appears that we have $\frac{qdx-pdy}{\sqrt{1+p^2+q^2}}$ = a complete differential, or, putting this $=d\zeta$, we introduce into the solution a variable ζ, which combines with z in the forms $z\pm i\zeta$ ($i=\sqrt{-1}$ as usual) The boundary conditions have to be satisfied by the determination of the conjugate variables η, η' as functions of $z+i\zeta$, $z-i\zeta$, or, say, of Z, Z' respectively, and by writing S, S' to denote $x+iy$, $x-iy$ respectively Riemann obtains finally two ordinary differential equations of the first order in S, S', η, η', Z, Z', and the results are completely worked out in some very interesting special cases.

The memoirs on various parts of the general subject are very numerous, references to many of them will be found in Salmon's *Treatise on the Analytic Geometry of Three Dimensions*, 4th ed, Dublin, 1882 (the most comprehensive work on solid geometry), for the minimal surface (which is not considered there) see Memoirs xviii and xxvi in Riemann's *Gesammelte mathematische Werke*, Leipsic, 1876, the former—"Ueber die Flache vom kleinsten Inhalt bei gegebener Begrenzung," as published in *Gott Abhandl*, vol xiii (1866-67)—contains an introduction by Hattendorff giving the history of the question (A CA.)

SURGEONS, COLLEGE OF See SOCIETIES

SURGERY

PART I —HISTORY.

SURGERY in all countries is as old as human needs A certain skill in the stanching of blood, the extraction of arrows, the binding up of wounds, the supporting of broken limbs by splints, and the like, together with an instinctive reliance on the healing power of the tissues, has been common to men everywhere In both branches of the Aryan stock surgical practice (as well as medical) reached a high degree of perfection at a very early period It is a matter of controversy whether the Greeks got their medicine (or any of it) from the Hindus (through the medium of the Egyptian priesthood), or whether the Hindus owed that high degree of medical and surgical knowledge and skill which is reflected in Charaka and Susruta (commentators of uncertain date on the Yajur-Veda, see SANSKRIT, vol xxi p 294) to their contact with Western civilization after the campaigns of Alexander The evidence in favour of the former view is ably stated by Wise in the Introduction to his *History of Medicine among the Asiatics* (London, 1868) The correspondence between the *Susruta* and the *Hippocratic Collection* is closest in the sections relating to the ethics of medical practice, the description, also, of lithotomy in the former agrees almost exactly with the account of the Alexandrian practice as given by Celsus But there are certainly some dexterous operations described

in Suśruta (such as the rhinoplastic) which were of native invention, the elaborate and lofty ethical code appears to be of pure Brahmanical origin, and the very copious materia medica (which included arsenic, mercury, zinc, and many other substances of permanent value) does not contain a single article of foreign source. There is evidence also (in Arrian, Strabo, and other writers) that the East enjoyed a proverbial reputation for medical and surgical wisdom at the time of Alexander's invasion. We may give the first place, then, to the Eastern branch of the Aryan race in a sketch of the rise of surgery, leaving as insoluble the question of the date of the Sanskrit compendiums or compilations which pass under the names of two representative persons, Charaka and Suśruta (the dates assigned to these ranging as widely as 500 years on each side of the Christian era).

Ancient Hindu practitioners. The *Suśruta* speaks throughout of a single class of practitioners who undertook both surgical and medical cases. Nor were there any fixed degrees or orders of skill within the profession, even lithotomy, which at Alexandria was assigned to specialists, was to be undertaken by any one, the leave of the rajah having been first obtained. The only distinction recognized between medicine and surgery was in the inferior order of barbers, nail-trimmers, ear-borers, tooth-drawers, and phlebotomists, who were outside the Brahmanical caste.

Surgical instruments. Suśruta describes more than one hundred surgical instruments, made of steel. They should have good handles and firm joints, be well polished, and sharp enough to divide a hair, they should be perfectly clean, and kept in flannel in a wooden box. They included various shapes of scalpels, bistouries, lancets, scarifiers, saws, bone-nippers, scissors, trocars, and needles. There were also blunt hooks, loops, probes (including a caustic-holder) directors, sounds, scoops, and forceps (for polypi, &c.), as well as catheters, syringes, a rectal speculum, and bougies. There were fourteen varieties of bandage. The favourite form of splint was made of thin slips of bamboo bound together with string and cut to the length required. Wise says that he has frequently used "this admirable splint," particularly for fractures of the thigh, humerus, radius, and ulna, and it has been subsequently adopted in the English army under the name of the "patent rattan-cane splint."

Operations. Fractures were diagnosed, among other signs, by crepitus. Dislocations were elaborately classified, and the differential diagnosis given, the treatment was by traction and countertraction, circumduction, and other dexterous manipulation. Wounds were divided into incised, punctured, lacerated, contused, &c. Cuts of the head and face were sewed. Skill in extracting foreign bodies was carried to a great height, the magnet being used for iron particles under certain specified circumstances. Inflammations were treated by the usual antiphlogistic regimen and appliances, venesection was practised at several other points besides the bend of the elbow, leeches were more often resorted to than the lancet, cupping also was in general use. Poulticing, fomenting, and the like were done as at present. Amputation was done now and then, notwithstanding the want of a good control over the hæmorrhage, boiling oil was applied to the stump, with pressure by means of a cup-formed bandage, pitch being sometimes added. Tumours and enlarged lymphatic glands were cut out, and an arsenical salve applied to the raw surfaces to prevent recurrence. Abdominal dropsy and hydrocele were treated by tapping with a trocar, and varieties of hernia were understood, omental hernia being removed by operation on the scrotum. Aneurisms were known, but not treated, the use of the ligature on the continuity of an artery, as well as on the cut end of it in a flap, is the one thing that a modern surgeon will miss somewhat noticeably in the ancient surgery of the Hindus, and the reason of their backwardness in that matter was doubtless their want of familiarity with the course of the arteries and with the arterial circulation. Besides the operation already mentioned, the abdomen was opened by a short incision below the umbilicus slightly to the left of the middle line, for the purpose of removing intestinal concretions or other obstruction (laparotomy). Only a small segment of the bowel was exposed at one time, the concretion when found was removed, the intestine stitched together again, anointed with ghee and honey, and returned into the cavity. Lithotomy was practised, without the staff. There was a plastic operation for the restoration of the nose, the skin being taken from the cheek adjoining, and the vascularity kept up by a bridge of tissue. The ophthalmic surgery included extraction of cataract. Obstetric operations were various, including cæsarean section and crushing the fœtus.

Medical treatment. The medication and constitutional treatment in surgical cases were in keeping with the general care and elaborateness of their practice, and with the copiousness of their materia medica. Ointments and other external applications had usually a basis of ghee (or clarified butter), and contained, among other things, such metals as arsenic, zinc, copper, mercury, and sulphate of iron. For every emergency and every known form of disease there were elaborate and minute directions in the śâstras, which were taught by the physician-priests to the young aspirants.

Training of practitioners. Book learning was considered of no use without experience and manual skill in operations, the different surgical operations were shown to the student upon wax spread on a board, on gourds, cucumbers, and other soft fruits, tapping and puncturing were practised on a leathern bag filled with water or soft mud, scarifications and bleeding on the fresh hides of animals from which the hair had been removed, puncturing and lancing upon the hollow stalks of water-lilies or the vessels of dead animals, bandaging was practised on flexible models of the human body, sutures on leather and cloth, the plastic operations on dead animals, and the application of caustics and cauteries on living animals. A knowledge of anatomy was held to be necessary, but it does not appear that it was systematically acquired by dissection. Superstitions and theurgic ideas were diligently kept up so as to impress the vulgar. The whole body of teaching, itself the slow growth of much close observation and profound thinking during the vigorous period of Aryan progress, was given out in later times as a revelation from heaven, and as resting upon an absolute authority. Pathological principles were not wanting, but they were derived from a purely arbitrary or conventional physiology (wind, bile, and phlegm), and the whole elaborate fabric of rules and directions, great though its utility must have been for many generations, was without the quickening power of reason and freedom, and became inevitably stiff and decrepit.

Chinese. The Chinese appear to have been far behind the Hindus in their knowledge of medicine and surgery, notwithstanding that China profited at the same time as Tibet by the missionary propagation of Buddhism. Surgery in particular had hardly developed among them beyond the merest rudiments, owing to their religious respect for dead bodies and their unwillingness to draw blood or otherwise interfere with the living structure. Their anatomy and physiology have been from the earliest times unusually fanciful, and their surgical practice has consisted almost entirely of external applications. Tumours and boils were treated by scarifications or incisions. The distinctive Chinese surgical invention is acupuncture, or the insertion of fine needles, of hardened silver or gold, for an inch or more (with a twisting motion) into the

seats of pain or inflammation. Wise says that "the needle is allowed to remain in that part several minutes, or in some cases of neuralgia for days, with great advantage"; rheumatism and chronic gout were among the localized pains so treated. There are 367 points specified where needles may be inserted without injuring great vessels and vital organs.

Egyptian.

Cupping-vessels made of cow-horn have been found in ancient Egyptian tombs. On monuments and the walls of temples are figures of patients bandaged, or undergoing operation at the hands of surgeons. In museum collections of Egyptian antiquities there are lancets, forceps, knives, probes, scissors, &c. Ebers interprets a passage in the papyrus discovered by him as relating to the operation of cataract. Surgical instruments for the ear are figured, and artificial teeth have been found in mummies. Mummies have also been found with well-set fractures. Herodotus describes Egypt, notwithstanding its fine climate, as being full of medical practitioners, who were all "specialists." The ophthalmic surgeons were celebrated, and practised at the court of Cyrus.

Greek.

As in the case of the Sanskrit medical writings, the earliest Greek compendiums on surgery bear witness to a long organic growth of knowledge and skill through many generations. In the Homeric picture of society the surgery is that of the battlefield, and it is of the most meagre kind. Achilles is concerned about the restoration to health of Machaon for the reason that his skill in cutting out darts and applying salves to wounds was not the least valuable service that a hero could render to the Greek host. Machaon probably represents an amateur, whose taste had led him, as it did Melampus, to converse with centaurs and to glean some of their traditional wisdom. Between that primitive state of civilization and the date of the first Greek treatises there had been a long interval of gradual progress. The surgery of the *Hippocratic Collection* (age of Pericles) bears every evidence of finish and elaboration.

Hippocratic surgery.

The two treatises on fractures and on dislocations respectively are hardly surpassed in some ways by the writings of the present mechanical age. Of the four dislocations of the shoulder the displacement downwards into the axilla is given as the only one at all common. The two most usual dislocations of the femur were backwards on to the dorsum ilii and forwards on to the obturator region. Fractures of the spinous processes of the vertebræ are described, and caution advised against trusting those who would magnify that injury into fracture of the spine itself. Tubercles (φύματα) are given as one of the causes of spinal curvature, an anticipation of Pott's diagnosis. In all matters of treatment there was the same fertility of resource as in the Hindu practice; the most noteworthy point is that shortening was by many regarded as inevitable after simple fracture of the femur. Fractures and dislocations were the most complete chapters of the Hippocratic surgery; the whole doctrine and practical art of them had arisen (like sculpture) with no help from dissection, and obviously owed its excellence to the opportunities of the palæstra. The next most elaborate chapter is that on wounds and injuries of the head, which refers them to a minute subdivision, and includes the depressed fracture and the *contrecoup*. Trephining was the measure most commonly resorted to, even where there was no compression. Numerous forms of wounds and injuries of other parts are specified. Ruptures, piles, rectal polypi, fistula in ano, and prolapsus ani were among the other conditions treated. The amputation or excision of tumours does not appear to have been undertaken so freely as in Hindu surgical practice, nor was lithotomy performed except by a specially expert person now and then. The diagnosis of empyema was known, and the treatment of it was by an incision in the intercostal space and evacuation of the pus. Among their instruments were forceps, probes, directors, syringes, rectal speculum, catheter, and various kinds of cautery.

Alexandrian period.

Between the Hippocratic era and the founding of the school of Alexandria (about 300 B.C.), there is nothing of surgical progress to dwell upon. The Alexandrian epoch stands out prominently by reason of the enthusiastic cultivation of human anatomy—there are allegations also of vivisection—at the hands of Herophilus and Erasistratus. The sum and substance of this movement appears to have been precision of diagnosis (not unattended with pedantic minuteness), boldness of operative procedure, subdivision of practice into a number of specialities, but hardly a single addition to the stock of physiological or pathological ideas, or even to the traditional wisdom of the Hippocratic time. "The surgeons of the Alexandrian school were all distinguished by the nicety and complexity of their dressings and bandagings, of which they invented a great variety." Herophilus boldly used the knife even on internal organs such as the liver and spleen, which latter he regarded "as of little consequence in the animal economy." He treated retention of urine by a particular kind of catheter, which long bore his name. Lithotomy was much practised by a few specialists, and one of them (Ammonius) is said to have used an instrument for breaking the stone in the bladder into several pieces when it was too large to remove whole. A sinister story of the time is that concerning Antiochus, son of Alexander, king of Syria, who was done to death by the lithotomists when he was ten years old, under the pretence that he had stone in the bladder, the instigator of the crime being his guardian and supplanter Diodotus.

The treatise of Celsus *De re medica* (reign of Augustus) reflects the state of surgery in the ancient world for a period of several centuries: it is the best record of the Alexandrian practice itself, and it may be taken to stand for the Roman practice of the period following. Great jealousy of Greek medicine and surgery was expressed by many of the Romans of the republic, notably by Cato the Elder (234-149 B.C.), who himself practised on his estate according to the native traditions. His medical observations are given in *De re rustica*. In reducing dislocations he made use of the following incantation: "Huat hanat ista pista sista damiato damnaustra." The first Greek surgeon who established himself in Rome is said to have been Archagathus, whose fondness for the knife and cautery at length led to his expulsion by the populace. It was in the person of Asclepiades, the contemporary and friend of Cicero, that the Hellenic medical practice acquired a permanent footing in Rome. This eloquent and plausible Greek confined his practice mostly to medicine, but he is credited with practising the operation of tracheotomy. He is one of those whom Tertullian quotes as abandoning themselves to vivisections for the gratification of their curiosity: "Asclepiades capras suas quærat sine corde balantes et muscas suas abigat sine capite volantes" (*De anima*, 15).

Cato Major.

Celsus.

The next figure in the surgical history is Celsus, who devotes the 7th and 8th books of his *De re medica* exclusively to surgery. There is not much in these beyond the precepts of the Brahmanical śâstras and the maxims and rules of Greek surgery. Plastic operations for the restoration of the nose, lips, and ears are described at some length, as well as the treatment of hernia by taxis and operation; in the latter it was recommended to apply the actual cautery to the canal after the hernia had been returned. The celebrated description of lithotomy is that of the operation as practised long before in India and at Alexandria. The treatment of sinuses in various regions is dwelt upon, and in the case of sinuses of the thoracic wall

resection of the rib is mentioned. Trephining has the same prominent place assigned to it as in the Greek surgery. The resources of contemporary surgery may be estimated by the fact that subcutaneous urethrotomy was practised when the urethra was blocked by a calculus. Amputation of an extremity is described in detail for the first time in surgical literature. Mention is made of a variety of ophthalmic operations, which were done by specialists after the Alexandrian fashion.

Galen's practice of surgery was mostly in the early part of his career (born 131 A.D.), and there is little of special surgical interest in his writings, great as their importance is for anatomy, physiology, and the general doctrines of disease. Among the operations credited to him are resection of a portion of the sternum for caries and ligature of the temporal artery. It may be assumed that surgical practice was in a flourishing condition all through the period of the empire from the accounts preserved by Oribasius of the great surgeons Antyllus, Leonides, Rufus, and Heliodorus. Antyllus (300) is claimed by Haser as one of the greatest of the world's surgeons; he had an operation for aneurism (tying the artery above and below the sac, and evacuating its contents), for cataract, for the cure of stammering; and he treated contractures by something like tenotomy. Rufus and Heliodorus are said to have practised torsion for the arrest of hæmorrhage; but in later periods both that and the ligature appear to have given way to the actual cautery. Haser speaks of the operation for scrotal hernia attributed to Heliodorus as "a brilliant example of the surgical skill during the empire." The same surgeon treated stricture of the urethra by internal section. Both Leonides and Antyllus removed glandular swellings of the neck (*strumæ*); the latter ligatured vessels before cutting them, and gives directions for avoiding the carotid artery and jugular vein. The well-known operation of Antyllus for aneurism has been mentioned before. Flap-amputations were practised by Leonides and Heliodorus. But perhaps the most striking illustration of the advanced surgery of the period is the freedom with which bones were resected, including the long bones, the lower jaw, and the upper jaw.

Whatever progress or decadence surgery may have experienced during the next three centuries is summed up in the authoritative treatise of Paulus of Ægina (650). Of his seven books the sixth is entirely devoted to operative surgery, and the fourth is largely occupied with surgical diseases. The importance of Paulus for surgical history during several centuries on each side of his own period will appear from the following remarks of Francis Adams in his translation and commentary (vol. ii. p. 247):—

"This book (bk. vi.) contains the most complete system of operative surgery which has come down to us from ancient times. ... Haly Abbas in the 9th book of his *Practica* copies almost everything from Paulus. Albucasis [Abulcasis] gives more original matter on surgery than any other Arabian author, and yet, as will be seen from our commentary, he is indebted for whole chapters to Paulus. In the *Continens* of Rhases, that precious repository of ancient opinions on medical subjects, if there be any surgical information not to be found in our author it is mostly derived from Antyllus and Archigenes. As to the other authorities, although we will occasionally have to explain their opinions upon particular subjects, no one has treated of surgery in a systematical manner; for even Avicenna, who treats so fully of everything else connected with medicine, is defective in his accounts of surgical operations; and the descriptions which he does give of them are almost all borrowed from our author. The accounts of fractures and dislocations given by Hippocrates and his commentator Galen may be pronounced almost complete; but the information which they supply upon most other surgical subjects is scanty."

It is obviously impossible in a brief space to convey any notion of the comprehensiveness of the surgery of Paulus; his sixth book, with the peculiarly valuable commentary of Adams, brings the whole surgery of the ancient world to a focus, and it should be referred to at first hand. Paulus himself is credited with the principle of local depletion as against general, with the lateral operation for stone instead of the mesial and with understanding the merits of a free external incision and a limited internal, with the diagnosis of aneurism by anastomosis, with an operation for aneurism like that of Antyllus, with amputation of the cancerous breast by crucial incision, and with the treatment of fractured patella.

The Arabians have hardly any greater merit in medicine than that of preserving intact the bequest of the ancient world. To surgery in particular their services are small,—first, because their religion proscribed the practice of anatomy, and secondly, because it was a characteristic of their race to accept with equanimity the sufferings that fell to them, and to decline the means of alleviation. The great names of the Arabian school, Avicenna and Averroes, are altogether unimportant for surgery. Their one distinctively surgical writer was Abulcasim (d. 1122), who is chiefly celebrated for his free use of the actual cautery and of caustics. He showed a good deal of character in declining to operate on goitre, in resorting to tracheotomy but sparingly, in refusing to meddle with cancer, and in evacuating large abscesses by degrees. Arabian

For the five hundred years following the work of Paulus of Ægina there is nothing to record but the names of a few practitioners at the court and of imitators or compilers. Meanwhile in western Europe (apart from the Saracen civilization) a medical school had gradually grown up at Salerno, which in the 10th century had already become famous. From it issued the *Regimen Salernitanum*, a work used by the laity for several centuries, and the *Compendium Salernitanum*, which circulated among the profession. The serious decline of the school dates from the founding of a university at Naples in 1224. In its best period princes and nobles resorted to it for treatment from all parts of Europe. The hôtel dieu of Lyons had been founded in 560, and that of Paris a century later. The school of Montpellier was founded in 1025, and became the rallying point of Arabian and Jewish learning. A good deal of the medical and surgical practice was in the hands of the religious orders, particularly of the Benedictines. The practice of surgery by the clergy was at length forbidden by the council of Tours (1163). The surgical writings of the time were mere reproductions of the classical or Arabian authors: "unus non dicit nisi quod alter." One of the first to go back to independent observation and reflexion was William of Saliceto, who belonged to the school of Bologna; his work (1275) advocates the use of the knife in many cases where the actual cautery was used by ancient prescription. A greater name in the history of mediæval surgery is that of his pupil Lanfranchi of Milan, who migrated (owing to political troubles) first to Lyons and then to Paris. He distinguished between arterial and venous hæmorrhage, and is said to have used the ligature for the former. Contemporary with him in France was Henri de Mondeville of the school of Montpellier, whose teaching is best known through that of his more famous pupil Guy de Chauliac; the *Chirurgie* of the latter bears the date of 1363, and marks the advance in precision which the revival of anatomy by Mondino had made possible. Eighteen years before Lanfranchi came to Paris a college of surgeons was founded there (1279) by Pitard, who had accompanied St Louis to Palestine as his surgeon. The college was under the protection of St Cosmas and St Damianus, two practitioners of medicine who suffered martyrdom in the reign of Diocletian, and it became known as the Collége de St Côme. From the time that Lanfranchi joined it it attracted many pupils. It maintained its independent existence for several centuries, Mediæval

alongside the medical faculty of the university, the corporation of surgeons in other capitals, such as those of London and Edinburgh, were modelled upon it.

The 14th and 15th centuries are almost entirely without interest for surgical history. The dead level of tradition is broken first by two men of originality and genius, Paracelsus and Paré, and by the revival of anatomy at the hands of Vesalius and Fallopius, professors at Padua. Apart from the mystical form in which much of his teaching was cast,

Paracelsus.

Paracelsus has great merits as a reformer of surgical practice. "The high value of his surgical writings," says Haser, "has been recognized at all times, even by his opponents." It is not, however, as an innovator in operative surgery but rather as a direct observer of natural processes that Paracelsus is distinguished. His description of "hospital gangrene," for example, is perfectly true to nature; his numerous observations on syphilis are also sound and sensible; and he was the first to point out the connexion between cretinism of the offspring and goitre of the parents. He gives most prominence to the healing of wounds. His special surgical treatises are *Die kleine Chirurgie* (1528) and *Die grosse Wund-Arznei* (1536-37),—the latter being the best known of his works. Somewhat later in date, and of much greater concrete importance

Paré.

for surgery than Paracelsus, is Ambroise Paré (1517-1590). He began life as apprentice to a barber-surgeon in Paris and as a pupil at the hôtel dieu. His earliest opportunities were in military surgery during the campaign of Francis I. in Piedmont. Instead of treating gunshot wounds with hot oil, according to the practice of the day, he had the temerity to trust to a simple bandage, and from that beginning he proceeded to many other developments of rational surgery. In 1545 he published at Paris *La méthode de traicter les playes faictes par hacquebutes et aultres bastons à feu*. The same year he began to attend the lectures of Sylvius, the Paris teacher of anatomy, to whom he became prosector; and his next book was an *Anatomy* (1550). His most memorable service was to get the use of the ligature for large arteries generally adopted, a method of controlling the hæmorrhage which made amputation on a large scale possible for the first time in history. Like Paracelsus, he writes simply and to the point in the language of the people, while he is free from the encumbrance of mystical theories, which detract not a little from the merits of his fellow-reformer in Germany. It is only in his book on monsters, written towards the end of his career, that he shows himself to have been by no means free from superstition. Pare was adored by the army and greatly esteemed by successive French kings; but his innovations were opposed, as usual, by the faculty, and he had to justify the use of the ligature as well as he could by quotations from Galen and other ancients.

Sixteenth century.

Surgery in the 16th century recovered much of the dexterity and resource that had distinguished it in the best periods of antiquity, while it underwent the developments opened up to it by new forms of wounds inflicted by new weapons of warfare. The use of the staff and other instruments of the "apparatus major" was the chief improvement in lithotomy. A "radical cure" of hernia by sutures superseded the old application of the actual cautery. The earlier modes of treating stricture of the urethra were tried; plastic operations were once more done with something like the skill of Brahmanical and classical times; and ophthalmic surgery was to some extent rescued from the hands of ignorant pretenders. It is noteworthy that even in the legitimate profession dexterous special operations were kept secret; thus the use of the "apparatus major" in lithotomy was handed down as a secret in the family of Laurence Colot, a contemporary of Paré's.

Seventeenth century.

The 17th century was distinguished rather for the rapid progress of anatomy and physiology, for the Baconian and Cartesian philosophies, and the keen interest taken in complete systems of medicine, than for a high standard of surgical practice. The teaching of Paré that gunshot wounds were merely contused and not poisoned, and that simple treatment was the best for them, was enforced anew by Magati (1579-1647), Wiseman, and others. Trephining was freely resorted to, even for inveterate migraine; Philip William, prince of Orange, is said to have been trephined seventeen times. Flap amputations, which had been practised in the best period of Roman surgery by Leonides and Heliodorus, were reintroduced by Lowdham, an Oxford surgeon, in 1679, and probably used by Wiseman, who was the first to practise the primary major amputations. Fabriz von Hilden (1560-1634) introduced a form of tourniquet, made by placing a piece of wood under the bandage encircling the limb; out of that there grew the block-tourniquet of Morel, first used at the siege of Besançon in 1674; and this, again, was superseded by Jean Louis Petit's screw-tourniquet in 1718. Strangulated hernia, which was for long avoided as a *noli me tangere*, became a subject of operation. Lithotomy by the lateral method came to great perfection in the hands of Jacques Beaulieu. To this century also belong the first indications (not to mention the Alexandrian practice of Ammonius) of crushing the stone in the bladder. The theory and practice of transfusion of blood occupied much attention, especially among the busy spirits of the Royal Society, such as Boyle, Lower, and others. The seat of cataract in the substance of the lens was first made out by two French surgeons, Quarré and Lasnier. Perhaps the most important figure in the surgical history of the century is Richard Wiseman, the

Wiseman.

father of English surgery. Wiseman took the Royalist side in the wars of the Commonwealth, and was surgeon to James I. and Charles I., and accompanied Charles II. in his exile in France and the Low Countries. After serving for a time in the Spanish fleet, he joined the Royalist cause in England and was taken prisoner at the battle of Worcester. At the Restoration he became serjeant-surgeon to Charles II., and held the same office under James II. His *Seven Chirurgical Treatises* were first published in 1676, and went through several editions; they relate to tumours, ulcers, diseases of the anus, king's evil (scrofula), wounds, fractures, luxations, and lues venerea. Wiseman was the first to advocate primary amputation (or operation before the onset of fever) in cases of gunshot wounds and other injuries of the limbs. He introduced also the practice of treating aneurisms by compression, gave an accurate account of fungus articulorum, and improved the operative procedure for hernia.

Eighteenth century.

The 18th century marks the establishment of surgery on a broader basis than the skill of individual surgeons of the court and army, and on a more scientific basis than the rule of thumb of the multitude of barber-surgeons and other inferior orders of practitioners. In Paris the Collége de St Côme gave way to the Academy of Surgery in 1731, with Petit as director, to which was added at a later date the École Pratique de Chirurgie, with Chopart and Desault among its first professors. The Academy of Surgery set up a very high standard from the first, and exercised great exclusiveness in its publications and its honorary membership. In London and Edinburgh the development of surgery proceeded on less academical lines, and with greater scope for individual effort. Private dissecting rooms and anatomical theatres were started, of which perhaps the most notable was Dr William Hunter's school in Great Windmill Street, London, inasmuch as it was the first perch of his more famous brother John Hunter. In Edinburgh, Alexander Monro, first of the name, became professor of anatomy to the company of surgeons in 1719,

transferring his title and services to the university the year after, as he was the first systematic teacher of medicine or surgery in Edinburgh, he is regarded as the founder of the famous medical school of that city In both London and Edinburgh a company of barbers and surgeons had been in existence for many years before, but it was not until the association of these companies with the study of anatomy, comparative anatomy, physiology, and pathology that the surgical profession began to take rank with the older order of physicians Hence the significance of the eulogy of a living surgeon on John Hunter "more than any other man he helped to make us gentlemen" (*Hunterian Oration*, 1877) The state of surgery in Germany may be inferred from the fact that the teaching of it at the new university of Gottingen was for long in the hands of Haller, whose office was "professor of theoretical medicine" In the Prussian army it fell to the regimental surgeon to shave the officers At Berlin a medico-chirurgical college was founded by surgeon-general Holtzendorff in 1714, to which was joined in 1726 a school of clinical surgery at the Charité Military surgery was the original purpose of the school, which still exists, side by side with the surgical cliniques of the faculty, as the Friedrich Wilhelm's Institute In Vienna, in like manner, a school for the training of army surgeons was founded in 1785,—Joseph's Academy or the Josephinum The first systematic teaching of surgery in the United States was by Dr Shippen at Philadelphia, where the medical college towards the end of the century was largely officered by pupils of the Edinburgh school Without attempting to enumerate the great names in surgery during the 18th century, it will be possible to introduce the more prominent of them in a brief sketch of the additions to the ideas and resources of surgery in that period A great part of the advance was in surgical pathology, including Petit's observations on the formation of thrombi in severed vessels, Hunter's account of the reparative process, Benjamin Bell's classification of ulcers, the observations of Duhamel and others on the formation of callus and on bone-repair in general, Pott's distinction between spinal curvature from caries or abscess of the vertebræ and kyphosis from other causes, observations by various surgeons on chronic disease of the hip, knee, and other joints, and Cheselden's description of neuroma Among the great improvements in surgical procedure we have Cheselden's operation of lithotomy (six deaths in eighty cases), Hawkins's cutting gorget for the same (1753), Hunter's operation (1785) for popliteal aneurism by tying the femoral artery in the canal of the triceps where its walls were sound ("excited the greatest wonder," Assalini), Petit's, Desault's, and Pott's treatment of fractures, Gimbernat's (Barcelona) operation for strangulated femoral hernia, Pott's bistoury for fistula, White's (Manchester) and Park's (Liverpool) excision of joints, Petit's invention of the screw-tourniquet, the same surgeon's operation for lacrymal fistula, Chopart's partial amputation of the foot, Desault's bandage for fractured clavicle, Bromfield's artery-hook, and Cheselden's operation of iridectomy Other surgeons of great versatility and general merit were Sharp of London, Gooch of Norwich, Hey of Leeds, David and Le Cat of Rouen, Sabatier, La Faye, Ledran, Louis, Morand, and Percy of Paris, Bertrandi of Turin, Troja of Naples, Palleta of Milan, Schmucker of the Prussian army, August Richter of Gottingen, Siebold of Wurzburg, Olof Acrel of Stockholm, and Callisen of Copenhagen

Nineteenth century

Two things have given surgical knowledge and skill in the 19th century a character of scientific or positive cumulativeness and a wide diffusion through all ranks of the profession The one is the founding of museums of anatomy and surgical pathology by the Hunters, Dupuytren, Cloquet, Blumenbach, Barclay, and a great number of more modern anatomists and surgeons, the other is the method of clinical teaching, exemplified in its highest form of constant reference to principles by Lawrence and Syme In surgical procedure the discovery of the anæsthetic properties of ether, chloroform, methylene, &c, has been of incalculable service, while the conservative principle in operations upon diseased or injured parts and what may be called the hygienic idea (or, more narrowly, the antiseptic principle) in surgical dressings have been equally beneficial The following are among the more important additions to the resources of the surgical art — the thin thread ligature for arteries, introduced by Jones of Jersey (1805), the revival of torsion of arteries by Amussat (1829), the practice of drainage by Chassaignac (1859), aspiration by Pelletan and recent improvers; the plaster-of-Paris bandage or other immovable application for simple fractures, club-foot, &c (an old Eastern practice recommended in Europe about 1814 by the English consul at Bassorah), the re-breaking of badly set fractures, galvano-caustics and écraseurs, the general introduction of resection of joints (Fergusson, Syme, and others), tenotomy by Delpech and Stromeyer (1831), operation for squint by Dieffenbach (1842), successful ligature of the external iliac for aneurism of the femoral by Abernethy (1806), ligature of the subclavian in the third portion by Astley Cooper (1806), and in its first portion by Colles, crushing of stone in the bladder by Gruithuisen of Munich (1819) and Civiale of Paris (1826), cure of ovarian dropsy by removing the cyst (since greatly perfected), discovery of the ophthalmoscope, and many improvements in ophthalmic surgery by Von Grafe and others, application of the laryngoscope in operations on the larynx by Czermak (1860) and others, together with additions to the resources of aural surgery and dentistry The great names in the surgery of the first half of the century besides those mentioned are —Scarpa of Italy (1747-1832), Boyer (1757-1833), Larrey (1766-1842),—to whom Napoleon left a legacy of a hundred thousand francs, with the eulogy "C'est l'homme le plus vertueux que j'aie connu,"—Roux (1780-1854), Lisfranc (1790-1847), Velpeau (1795-1868), Malgaigne (1806-1865), Nélaton (1807-1873),—all of the French school, of the British school, John Bell, Charles Bell, Allan Burns, Liston, Wardrop, Astley Cooper, Cline, Travers, Brodie, Stanley, and Guthrie, in the United States, Mott, Gross, and others, in Germany, Kern and Schuh of Vienna, Von Walther and Textor of Wurzburg, Chelius, Hesselbach, and the two Langenbecks In surgical pathology the discoveries and doctrines of the 19th century are greater in scientific value than those of any antecedent period, and it would be unprofitable to attempt any enumeration of them, or of their authors, in a brief space

The authorities mostly used have been—Wise, *History of Medicine among the Asiatics*, 2 vols, London, 1868, *Paulus Ægineta*, translated with commentary on the knowledge of the Greeks, Romans, and Arabians, in medicine and surgery, by Francis Adams, 3 vols, London, 1844 47, Haser, *Gesch d Medicin*, 3d ed, vols i and ii, 1875 81 (C C)

Part II —Practice of Surgery

A great change has taken place in the practice of surgery since the publication (1860) of the article Surgery in vol xx of the 8th edition of the present work This change is due in great part to the fact that the germ theory of disease has been accepted by the majority of surgical teachers and practitioners Scientific men have demonstrated that the causation of many diseased conditions is closely connected with the presence in the diseased organ, tissue, or individual of living organisms, which have to a certain extent been classified, and are supposed to be forms

of plant life In one sense it is perhaps unfortunate that the article on surgery has to be written at the present time, because, while there are few who now hold that these organisms are inert, there are some who do not grant that they are the cause of disease, and there are many differences of opinion as to the best methods of applying this scientific knowledge to practical use In other words, although much of the surgical practice of the present day is founded on a scientific basis, the practical details are still matter of dispute

Improvements in wound treatment

It is impossible in the present sketch to go with any fulness into the details of the experimental research by which the truth of the germ theory was proved, but some allusion must be made to the salient points which have a bearing on the work of the surgeon It has long been known that subcutaneous injuries follow, as a rule, a very different course from open wounds, and the past history of surgery gives evidence that surgeons not only were aware of this great difference but endeavoured, by the use of various dressings, empirically to prevent the evils which were matters of common observation during the healing of open wounds Various means were also adopted to prevent the entrance of air, *e g*, in the opening of abscesses by the "valvular method" of Abernethy, and by the subcutaneous division of tendons in the common deformity termed "club-foot" Balsams, turpentine, and various forms of spirit were the basis of many varieties of dressing These different dressings were frequently cumbersome, difficult of application, and did not attain the object aimed at, while at the same time they retained the discharges, and gave rise to other evils which prevented rapid and painless healing In the beginning of the 19th century these complicated dressings began to lose favour, and practical surgeons went to the opposite extreme and applied a simple dressing, the main object of which was to allow a free escape of discharge Others applied no dressing at all, laying the stump of a limb after amputation on a piece of dry lint, avoiding thereby any unnecessary movement of the parts Others left the wound open for some hours after an operation, preventing in this way any accumulation, and brought its edges and surfaces together after all oozing of blood had ceased and after the effusion, the result of injury to the tissues by the instruments used in the operation, had to a great extent subsided As a result of these various improvements many wounds healed in a thoroughly satisfactory manner But in other cases inflammation often occurred, accompanied by pain and suppuration or the formation of pus, and various feverish conditions, due to and in some way connected with the unhealthy state of the wound, were observed These constitutional sequelæ frequently proved fatal and the general impression of surgeons was either that the constitution of the patient rendered him liable to these conditions, or that some poison had entered into the wound, and, passing from it into the veins or lymphatic vessels that had been cut across, reached the general circulation, contaminating the blood and poisoning the patient The close clinical association between suppuration (or the formation of pus) in wounds and many of those fatal cases encouraged the belief that the pus cells from the wound entered the circulation (whence the word "pyæmia") It was also frequently observed that a septic condition of the wound was associated with the constitutional fever, and it was supposed that the septic matter passed into the blood (whence the term "septicæmia") It was further observed that the crowding together of patients with open wounds increased the liability to these constitutional disasters, and every endeavour was made by surgeons to separate their patients and to improve the ventilation of the larger hospitals In building hospitals the pavilion and other systems, with windows on both sides and cross ventilation in the wards, were adopted in order to give the patients as much fresh air as was attainable Hospital buildings were spread over as large an area as possible, the blocks were restricted in height, and if practicable were never higher than two stories The term "hospitalism" was coined by Sir J Y Simpson, who collected statistics comparing hospital and private practice, by which he endeavoured to show that private patients were not so liable to those constitutional sequelæ

Lister's germ theory, and treatment of wounds

This was very much the condition of affairs when Lister in 1860, from a study of the experimental researches of Pasteur into the causes of putrefaction, stated that the evils observed in open wounds were due to the admission into them of organisms which exist in the air, in water, on instruments, on sponges, and on the hands of the surgeon These organisms, finding a suitable nidus for their growth and development in the discharges and surrounding tissues, germinate in them and alter their chemical constitution, forming various poisonous compounds, which, if absorbed into the blood, give rise to pyæmia and septicæmia Having accepted the germ theory of putrefaction, he applied himself to discover the best way of preventing these organisms from reaching the wound from the moment that it was made until it was healed He had to deal with a plant and he desired to interfere with its growth This was possible in one of two ways,—either (1) by directly destroying or paralysing the plant itself before it entered the wound or after it had entered, or (2) by an interference with the soil in which it grew, for example, by facilitating the removal of the discharges and preventing their accumulation in the wound cavity, and by doing everything to prevent depression of the wounded tissues, because healthy tissues are the best of all germicides Several substances were then known possessing properties antagonistic to sepsis or putrefaction, and hence called "antiseptic" Acting on a suggestion of Lemaire's, Lister chose for his experiments carbolic acid, which he used at first in a crude and impure form He had many practical difficulties to contend with,—the impurity of the substance, its irritating properties, the difficulty of finding the exact strength in which to use it on the one hand, he feared to use it too strong, lest it should irritate the tissues to which it was applied and thus prevent healing, on the other hand, he feared to use it too weak, lest its true antiseptic qualities should be insufficient for the main object in view It is unnecessary to dwell on the details of his tentative experiments As dressings for wounds he used various chemical substances, which, being mixed with carbolic acid in certain proportions, were intended to give off a quantity of carbolic acid in the form of vapour, so that the wound might be constantly surrounded by an antiseptic vapour which would destroy any organisms approaching it and at the same time not interfere with its healing At first, although he prevented pyæmia in a marked degree, he, to a certain extent, irritated his wounds and prevented rapid healing He began his experiments in Glasgow and continued them after his removal to the chair of clinical surgery in Edinburgh After many disappointments, he gradually perfected his method of performing operations and dressing wounds, which will be best understood by an illustration

Amputation at ankle joint

A patient is suffering, let us say, from a diseased condition of the foot necessitating amputation at the ankle joint The part to be operated on is enveloped in a towel which has been soaked with a 5 per cent solution of carbolic acid The towel is applied two hours before the operation, with the object of destroying the (putrefactive) organisms present in the skin The patient is placed on the operating table, and brought under the influence of

chloroform, the limb is elevated to empty it of blood, and a tourniquet is applied round the limb below the knee. The instruments to be used during the operation have been previously purified by lying for half an hour in a flat porcelain dish containing carbolic acid (1 to 20). The sponges are lying in a similar carbolic lotion. Towels soaked in the same solution are laid over the table and blankets near the part operated upon. The hands of the operator, as well as those of his assistants, are thoroughly purified by washing them in the same lotion, free use being made of a nail brush for this purpose. The operation is performed under a cloud of carbolized watery vapour (1 in 30) from a steam-spray producer. The visible bleeding points are first ligatured; the tourniquet is removed; and then any vessels that have escaped notice are ligatured. The wound is stitched, a drainage-tube made of red rubber being introduced at one corner to prevent accumulation of discharge; a strip of protective (oiled silk coated with carbolized dextrin) is washed in carbolic lotion and applied over the wound. A double ply of carbolic gauze[1] is soaked in the lotion and placed over the protective, overlapping it freely. A dressing consisting of eight layers of dry gauze is placed over all, covering the stump and passing up the leg for about 6 inches. Over that a piece of thin Mackintosh cloth is placed, and the whole arrangement is fixed with a gauze bandage. The Mackintosh cloth prevents the carbolic acid from escaping and at the same time causes the discharge from the wound to spread through the gauze. The wound itself is protected by the protective from the vapour given off by the carbolic gauze, whilst the surrounding parts, being constantly exposed to its activity, are protected from the intrusion of septic contamination; and these conditions are maintained until sound healing has taken place. Whenever the discharge reaches the edge of the Mackintosh the case requires to be dressed, and a new supply of gauze applied round the stump. The gauze that is used should be freshly made and kept in a tin box to prevent evaporation of the volatile carbolic acid. This precaution is most needful in warm weather. Whenever the wound is exposed the stump is enveloped in a vapour (1 in 30) of carbolic acid by means of the steam-spray producer. At first a syringe was used to keep the surface constantly wet with lotion, then a hand-spray, such as Richardson's ether-spray producer. More recently a steam-spray producer has been introduced into practice. These dressings are repeated at intervals until the wound is healed, the drainage-tube being gradually shortened and ultimately removed altogether.

In the case of an accidental wound to which the surgeon is called a short time after its occurrence, carbolic lotion (1 to 20) must be injected into the cavity of the wound to destroy any organisms which may have fallen into it. The dressings already described are then applied. In operating on a case in which putrefaction has occurred, every endeavour must be made to destroy the causes of putrefaction which are already present. The substance most frequently used for this purpose is chloride of zinc solution, 40 grains to 1 oz. of water. This powerful antiseptic was extensively used some years ago by Mr De Morgan, Middlesex Hospital, London. When the wound has been thus purified from its septic condition, the after-treatment must follow strictly the plan already recommended for a recent wound to avoid secondary contamination at subsequent dressings.

Progress since Lister.

The object Lister had in view from the beginning of his experiments was to place the open wound in a condition as regards the entrance of organisms as closely analogous as possible to a truly subcutaneous wound, such as a contusion or a simple fracture, in which the unbroken skin acts as a protection to the wounded tissues beneath. The introduction of this practice by Lister effected a complete change in operative surgery. Although the principle on which he founded it was at first denied by many, it is now very generally acknowledged to be correct. In Germany more especially his views were speedily accepted. In France and England their adoption was slower. In Scotland, perhaps in consequence of the fact that many saw him at work and worked under him, acquiring perhaps some little part of his persevering enthusiasm, he soon had many believers. Since about 1875 surgeons have been trying to improve and simplify the method; chemists have been at pains to supply carbolic acid in a pure form and to discover new antiseptics, the great object being to get a non-irritating substance which shall at the same time be a powerful germicide. Iodoform, eucalyptus, salicylic acid, boracic acid, corrosive sublimate, have been and are being used, and the question as to their relative superiority is not yet settled. Carbolic acid has the disadvantage of irritating the tissues. This is partly counterbalanced by its anæsthetic properties. Absorption of the carbolic acid has occasionally taken place, giving rise to symptoms of poisoning. But this danger has been greatly lessened by the introduction of pure acid. Of the antiseptics named carbolic acid, eucalyptus, and iodoform are volatile; the rest are non-volatile. At first Lister for some years irrigated a wound with carbolic lotion during the operation, and at the dressings when it was exposed. The introduction of the spray displaced the irrigation method. At the present time the irrigation method is again gaining favour. All these different procedures, however, as regards both the antiseptic used and the best method of its application in oily and watery solutions and in dressings, are entirely subsidiary to the great principle involved—namely, that putrefaction in a wound is an evil which can be prevented, and that, if it is prevented, local irritation, in so far as it is due to putrefaction, is obviated and septicæmia and pyæmia do not occur. Alongside of this great improvement the immense advantage of free drainage is now universally acknowledged. Surgeons now understand the dangers which lie on every side, and this knowledge causes them to take greater care in the purification and in securing the greater cleanliness of wounds, and some hold that much of the good result follows from these precautions apart from the principle of the system.

Putrefactive organisms.

Putrefaction has been clearly shown by Pasteur, Tyndall, and others to be due to the activity of certain lowly forms of organized matter. Scientific men have therefore had their attention more particularly directed to these lower forms of plant life. A careful study has been made of their life history, and several diseased conditions are now known to be due to the deposit and growth of organisms of a specific form in the blood and in the tissues. This is not the place to discuss points still *sub judice*; but there can be no doubt, *e.g.*, that the *Bacillus anthracis* is the cause of splenic fever and of its local manifestation, malignant pustule, and that erysipelas is due to the presence of a micrococcus. There are many other diseases spoken of as zymotic or fermentative, upon which observers are now at work, and hardly a month passes without the publication of new observations (compare SCHIZOMYCETES). It can

[1] The gauze dressing consists of thin gauze which has been soaked in a mixture of carbolic acid (1 part), resin (5 parts), and paraffin (7 parts). The object of the paraffin is to prevent the gauze sticking to the skin. The resin retains the carbolic acid and prevents evaporation at the ordinary temperature; at the temperature of the body, however, a certain quantity of the carbolic acid is constantly being given off, and in this way the part operated on is enveloped in a vapour of carbolic acid. This antiseptic vapour persists as long as there is any carbolic acid in the gauze. A gauze dressing is not reliable for more than a week; by that time the carbolic acid in the gauze is dissipated and the dressing requires to be renewed.

certainly be said that the relation between those organisms and various specific diseases is the question which at present most occupies the attention both of pathologists and of practitioners of medicine and surgery. It is now known that there are many varieties of organisms (in Crookshank's *Bacteriology* sixty are described), some of which are hurtful to the human economy, though others are apparently harmless. Those of the former class give rise to an alteration in the tissue in which they grow, and during their growth they alter its composition and cause it to break up into various compounds, some of which, when absorbed into the blood-stream, poison the individual. Some, on the other hand, are either in themselves innocuous or are killed when they enter the blood, which is a fluid tissue and acts as a germicide, hence the tissues in a healthy condition are spoken of as "germicidal." Some apparently grow only on dead tissue, or in tissue the vitality[1] of which has been lowered.

Fermentations. The alteration in the tissue is strictly analogous to a fermentation—such, for example, as the change which takes place in a solution of grape sugar in which the yeast plant has been planted. The solution breaks up into alcohol and carbonic acid, along with this change there is an increase in the quantity of the yeast. The most common fermentation is the alteration termed "putrefactive" or "septic." The cause of this change is in all probability a special organism named *Bacterium termo*. It lives on any dead matter containing nitrogen when exposed to heat and moisture, dryness and cold are antagonistic to its growth. Its results are so evident and of such common observation that the term "antiseptic" was used long before the primary cause of the condition was understood. Antiseptics originally were substances which interfered with sepsis. The term has now, however, a wider meaning, and includes any substance opposed to fermentation. "Antifermentative" or "antitheric" would be a better term. An antitheric substance is one which interferes with fermentation by destroying or paralysing the organism which is the primary cause of the condition. The word "antiseptic," on the other hand, should be reserved to denote any substance which is opposed to putrefaction or sepsis,—one form of fermentation. Many of the most dangerous fermentations have nothing in common with putrefaction: the products which result are odourless, the appearances which arise bear no similarity to the changes which occur when putrefactive fermentation is present. Plant the *Bacterium lactis* in milk, and souring, or the lactic acid fermentation, takes place, plant the *Bacterium termo* in milk, and putrefactive fermentation occurs. The fermentations of smallpox, vaccinia, syphilis, scarlet fever, typhoid, relapsing fever, typhus, erysipelas, and cholera may be taken as examples of fermentations of the non-putrefactive class. Apparently in them the organism enters the blood-stream, there develops and forms its products, which, acting directly or indirectly on the heat-centre, give rise to a specific fever. This fever continues until the soil is worn out, and the organism, finding no longer a nidus for its development, dies out, and recovery takes place. Death of course results if the individual has not sufficient strength to withstand the attack. There is a general law regarding all living things which holds true of these lowly organisms as of the highest: remove its food and the organism dies, or at any rate ceases to develop. It may, however, lie quiescent, again appearing when a new nidus is provided for it. These considerations explain the reason why, after one attack, the individual is protected for a longer or shorter period. They also explain why many diseases are becoming through course of time less virulent than they once were: the soil is becoming exhausted in relation to the special requirements of the organism, and the organism is therefore incapable of flourishing as it formerly did. Plant the organism in a virgin soil—take, for example, as was unwittingly done, the organism of measles to Fiji—and a disease which in Great Britain is comparatively harmless becomes a most deadly scourge.

Infective and non-infective organisms. An attempt has been made to divide organisms into two great divisions—the infective and the non-infective. The first class can grow in living tissue, the second cannot. The first form their products in living matter, the second can only grow in dead or lowly vitalized matter. The infective organism can migrate from the original point of entrance by the vascular and lymphatic streams to distant parts of the body, and may there form secondary foci of infection. As regards the non-infective the manufactory of the poison is principally restricted to the near neighbourhood of the original point of entrance, generally a wound. It cannot migrate into the living tissues around if they remain healthy. Both kinds of organism form ptomaines (πτῶμα, a carcase), the products of the fermentation which result from the breaking up of the tissue or discharge in which the organisms grow. They may enter the blood-stream and poison the patient. Their entry into the blood must be differentiated from the entry of the organism itself into the stream. Clinically, the two conditions, although often met with in one individual, are in many cases distinctly separable. This physiological division of organisms into infective and non-infective is at present only tentative, and much work must be done before a strictly physiological classification can be attempted, at present the main line of inquiry must be principally morphological. Even in this direction a difficulty meets the observer, because organisms change their shape according to the media in which they are cultivated.

In the present article only a general view of the present aspects of surgical practice can be given. Special stress will be laid upon the principles which guide the surgeon in his daily work. For full particulars with reference to any special points the reader is referred to Holmes's *System of Surgery*, Erichsen's *Science and Art of Surgery*, and Gross's *System of Surgery*.

Surgical affections may be divided into two great classes,—those which are the result (1) of injury and (2) of disease.

I. INJURIES.

Shock. Before proceeding to the consideration of the different injuries it will be necessary to say a few words about the general condition termed *shock* or *collapse*, which supervenes after a severe injury. Care must be taken not to confound this state with faintness or syncope from loss of blood. Undoubtedly in many cases both conditions are present. Syncope from loss of blood is considered below. Syncope from mental emotion differs from shock in degree only. In shock the patient is pale, and bathed in cold clammy perspiration, his sensibility is blunted, his pulse is small and feeble, he is unable to make any active exertion, but lies in bed indifferent to external circumstances, and can only be roused with difficulty, he frequently complains of a feeling of cold, and he may have a distinct shivering or rigor. These symptoms may continue for some hours, the first evidence of improvement is that he shifts his position in bed and complains of the pain of the injury which has caused the condition. The pulse becomes stronger, and he then passes from the state of shock into the condition of reaction. If the improvement continues recovery will take place, but if it is only transient the patient will sink back again into a drowsy condition, which, if it persists, will end in death. In severe cases there may be no reaction, the patient then gradually becomes weaker and weaker, his pulse feebler and feebler, till death ensues. Shock is due to an impression conveyed to the central nervous system by an afferent nerve of common or special sensation. This impression produces a change in the medulla oblongata, by which the nerve centres are so affected that a partial paralysis or paresis of the voluntary and involuntary muscular fibres in the body takes place. In consequence of the change in the voluntary muscles the patient is unable to lift his arm or move his leg, the respiratory functions are performed wearily, and the

[1] John Hunter defines "vitality" as the power which resists putrefaction.

muscle of the heart contracts feebly, the muscular fibres in the walls of the blood-vessels lose their tonicity and the blood-vessels dilate, the blood collects in the large venous trunks, more especially of the abdomen, the vessels of the skin are emptied of blood, giving rise to the marked pallor. Two of the great causes that keep up the normal circulation of the blood through the body are in partial abeyance: the heart has not sufficient energy to contract, and there is not a sufficient quantity of blood passing into it from the blood vessels. The heart beats feebly (1) because its nervous energy is lowered, and (2) because it has not a sufficient quantity of blood to act upon. An understanding of these facts gives the general indications for treatment,—(1) external stimulation over the heart by mustard poultices or turpentine stupes, (2) elevation of the limbs, to cause the blood to gravitate towards the heart, (3) manual pressure on the abdominal cavity from below upwards, to encourage the flow of blood from the dilated abdominal veins into the heart. These different measures may be supplemented by the administration of stimulants by the mouth, or, if the patient cannot swallow, by subcutaneous injection of a diffusible stimulant, such as ether or ammonia.

Syncope. In syncope or faintness from mental emotion the weakened heart cannot drive a sufficient quantity of blood to the brain, the patient feels dizzy and faint and falls down insensible. The condition is a transitory one, and the recumbent posture, assisted if need be by elevation of the limbs, causes the blood to gravitate to the heart, which is thereby stimulated to contraction, a sufficient quantity of blood is then driven onwards to the brain, and the insensibility passes off. If the patient is in the sitting posture when he feels faint, the head should be depressed between the knees, which will cause the blood to rush to the brain, and the faintness will pass off.

Hæmorrhage. With few exceptions the soft parts are freely supplied with blood vessels, and as a preliminary to a consideration of the different forms of injuries it will be well to say a few words about hæmorrhage or bleeding. If a blood vessel is torn or cut across, the blood within it escapes, either externally on to the clothes or floor, or, in the case of a subcutaneous injury, into the tissues, giving rise to *ecchymosis*. Cessation of the bleeding may take place in consequence of an arrest of the hæmorrhage either by nature's effort or by the adoption of artificial means by the surgeon. The loss of blood may be so great that the heart's propelling power is weakened, and in this way the natural arrest is assisted. But there is always a danger that with the arrest of the hæmorrhage the heart's action may recover its power and the bleeding recommence. In arresting hæmorrhage temporarily the chief thing is to press directly on the bleeding part. The pressure to be effectual need not be severe, but must be accurately applied. If the bleeding point cannot be reached, the pressure should be applied to the main artery between the bleeding point and the heart. In small blood-vessels pressure will be sufficient to arrest hæmorrhage permanently. In large vessels it is usual to pass a ligature round the vessel and tie it with a reef knot. Apply the ligature also, if possible, at the bleeding point, tying both ends of the cut vessel. If this cannot be done, the main artery of the limb must be exposed by dissection at the most accessible point between the wound and the heart, and there ligatured. Hæmorrhage has been classified in three varieties—(1) primary, occurring at the time of the injury, (2) reactionary, or within twelve hours of the accident, during the stage of reaction, (3) secondary, occurring at a later period, and caused by unhealthy processes attacking the wound and giving rise to ulceration of the coats of the blood-vessels. In treating these different varieties the principles already laid down hold good. In cases of severe hæmorrhage the patient suffers from syncope owing to loss of blood. Syncope from loss of blood is to be treated on the same principles as those already laid down for shock. But in addition it may be necessary in cases of severe hæmorrhage, in which much blood has been lost, to introduce into the circulation fluid which will give the heart something to act upon. Blood drawn directly from the arm of a healthy person, and introduced through an opening in the vein of the arm, has frequently been made use of. The tendency of the blood to coagulate when brought in contact with foreign matter has led to the adoption of ingenious instruments to avoid this danger. Some surgeons have used defibrinated blood, and others milk. The opinion is at present gaining ground that a nutrient fluid is unnecessary, and that all that is required is to introduce an aseptic neutral fluid at the temperature of the body which has no tendency to cause coagulation of the blood with which it mixes. A saline solution, composed of 75 per cent of common salt in distilled water, fulfils all these requirements, 4 to 6 oz are generally sufficient. Recent experiments have been made by which blood drawn from the arm of the giver is mixed with a solution of phosphate of soda. This admixture prevents the blood from coagulating, and it can be introduced into the blood-stream with safety.

Contusions. In a recent contusion careful pressure should be applied, with cotton wadding fixed in position with a bandage. The aim is to prevent ecchymosis and to hasten the absorption of the effused blood after it has escaped into the tissues. Accurate pressure fulfils these ends more perfectly than the commoner application of cold.

Wound treatment. The procedure for the treatment of an open wound is—(1) arrest of hæmorrhage, (2) removal of any foreign bodies in the wound, (3) careful apposition of its edges and surfaces,—the edges being best brought in contact by the use of horse-hair stitches, the surfaces by carefully applied pressure, (4) free drainage of the wound to prevent accumulation either of blood or of serous effusion, which may be done—(*a*) by leaving the dependent corner open, or (*b*) by introducing a drainage-tube, a skein of catgut, or a skein of horse-hair, (5) avoidance of putrefaction by the use of antiseptic precautions, (6) perfect rest of the part by appropriate means during the cure. These methods of treatment require to be modified for wounds in special situations and for those in which there is much contusion and laceration. In punctured wounds free drainage is of primary importance.

Poisoned wounds. When a special poison has entered the wound at the time of its infliction or at some subsequent date the following dangers have to be combated—(1) an intense inflammation in the wound itself and surrounding parts, (2) inflammation of the lymphatic vessels leading from it, (3) inflammation of the lymphatic glands, (4) blood poisoning of the general circulation. One of the commonest poisons is that connected with wound putrefaction, of others some are the result of diseased action in the lower animals, *e g*, hydrophobia, whilst some are special diseases in man. These diseased conditions are at the present time being carefully studied, and the observations all tend to one conclusion, that they are due to specific organisms which have found entrance into the diseased animal or man, and, finding there a suitable nidus for their growth and development, have set up a specific disease. If the surgeon is accidentally wounded in operating on the living subject, or the pathologist in making a post mortem examination, the poison may pass into the wound and give rise to one or more of the symptoms already indicated. There can be no doubt that these special poisons,[1] which are spoken of as pathogenic or infective, are in some way associated with low forms of plant life, and that in this they resemble the poison of putrefaction. If the operator is in good health the poison will generally have little effect, if he is in bad health the effect may be very severe. We do not yet know in what cases bad results are to be expected. The great point in every doubtful case is to purify the wound thoroughly with some powerful antiseptic, so as to destroy the poison at the point of inoculation. If the poison escapes the germicidal action of the antiseptic used and enters the system, the patient should be stimulated, as the poison exercises a depressing action. For hydrophobia no cure is at present known. Experiments are, however, now (1887) being made by Pasteur which will throw some light on this dreadful disease.

Burns. Burns are dangerous accidents in young children and in old people when the areas affected are large, and when they are situated over the cavities of the body. The patient may die of shock soon after the accident, of deep-seated inflammations coming on during the stage of reaction, or of hectic, which in all probability is a form of chronic pyæmia associated with profuse discharge from the wounded surface. To prevent death from any of these causes stimulating treatment is necessary. It has long been known that it is important to keep the air from the wounded surface, and antiseptic dressings must be used to prevent the access of organisms to it. When the skin is destroyed to any great extent contraction is apt to take place, followed by deformity. Care must be taken during the process of cure to prevent this, by keeping the limb in an extended position during the treatment of burns on the flexor surface. To hasten cicatrization after a burn in which the skin has been destroyed grafts of epidermic tissue may be planted on the granulating surface according to the method of Reverdin. These grafts, each the size of a pin's head, become fixed and from them cicatrization spreads over the surface. After cicatrization the tendency to contraction is not nearly so great. Epidermis grafting must not be confounded with skin grafting, in which the grafts are of the whole thickness of the skin.

Fracture. A bone may be broken at the part where it is struck, or it may break in consequence of a strain applied to it. In the former case the fracture is generally transverse and in the latter more or less oblique in direction. The fully developed bone is broken fairly across, the soft bones of young people may simply be bent—"*green stick*" or "*willow*" *fracture*. Fractures are either simple or compound. A simple fracture is analogous to the contusion or subcutaneous laceration in the soft parts, a compound fracture is analogous to the open wound in the soft parts. The wound of the soft parts in the compound fracture may be caused either by the same force which has caused the fracture, as in the case of a cart wheel going over a limb, first wounding the soft parts and then fracturing the bone, or by the sharp point of the fractured bone coming through the skin. In either case there is a communication between the external air and the injured bone. As some years elapse before the epiphyseal extremities of the bone become united by osseous deposit to the shaft, external violence may cause a

1 For their classification, as yet very imperfect, consult Ziegler's *Pathological Anatomy* (trans by Macalister, London, 1883 84)

separation of the epiphysis from the shaft. This variety of fracture is termed a *diastasis*. When a bone is broken there is generally distortion and preternatural mobility, inability to use the limb, and pain on pressure over the fractured part. In the majority of fractures there is also crepitus,—the feeling elicited when two osseous surfaces are rubbed together. When a bone is bent, or when a diastasis has occurred, there is no crepitus. It is also absent in impacted fractures, in which the broken extremities are driven into one another. In order to get firm osseous union in a case of fracture the great points to attend to are accurate apposition of the fragments and complete rest of the broken bone. Accurate apposition is termed "setting the fracture"; this is best done by the extension of the limb and coaptation of the broken surfaces. Complete rest is attained by the use of appropriate splints. As a rule it is of great importance to command the joint above and below the seat of fracture. In cases of fracture near a joint, in which very commonly a splintering of the bone into the joint has taken place, more especially in those cases in which numerous tendons in their tendinous sheaths have been stretched, if the surgeon forgets that there may be effusion into the joint and the tendinous sheaths, and that this effusion may form fibrous tissue leading to stiffness of the joint and stiffening of the tendons, the result, more especially in old people, will be a permanently stiff joint or permanently stiffened tendons. Care must be taken in such instances by gentle passive movement during the process of cure to keep the joint and tendons free from the fibrous formation. To take a common example,—in fracture of the radius close to the wrist joint, it is necessary to apply appropriate splints to keep the bone at rest, and to arrange them so that the patient can move his fingers and thumb to prevent stiffness, and the splints must be taken off occasionally in order to move the wrist joint gently. If, however, the splints extend to the points of the fingers and are kept on for some weeks without removal, the consequence is a normal radius and a useless hand. Instances occasionally occur in which non-union results, either from want of formative power on the part of the individual or in consequence of improper treatment by the surgeon. For the treatment of this condition the reader is referred to one of the systematic works mentioned above. For fractures of the cranium see below, p. 688.

Treatment of compound fractures. There is no form of injury in which the truth of the principles first advocated by Lister has been more prominently brought forward than in compound fractures. When such an accident occurs from direct violence the soft parts are generally much crushed and the bone is frequently comminuted. When a bone is broken from indirect violence the fracture is frequently oblique and the sharp point of the bone projects through the skin. In such a case the injury is, as a rule, not so severe. Formerly compound fractures were the dread of the surgeon; septic inflammation occurring in the wound reached the open medullary cavity of the bone, and the open blood-vessels of the bone gave easy access to the causes and products of the inflammation into the general blood stream, giving rise to pyæmia. It is not asserted, however, that this accident always occurred. In a case of compound fracture the wound should be at once covered with a towel thoroughly soaked in a five per cent. solution of pure carbolic acid. And, if some time elapses before the arrival of a surgeon, more of the solution must be poured upon the towel, which should be kept thoroughly soaked. After the fracture is set it will probably be necessary to inject the solution into the interstices of the wound, over which an efficient antiseptic dressing must be applied. When the injury is so severe that it is impossible to preserve the limb, amputation is the only resource. It is often a difficult thing to say when the surgeon should amputate. The question will frequently be settled by a consideration of the general circumstances and surroundings of the patient, and no definite rules can be laid down. Speaking in general terms, an artificial substitute may take the place of the lower limb, but no artificial substitute can ever efficiently take the place of the upper limb; and therefore surgeons will run some risk in attempting to save an upper limb which they will not do in treating an injury of a lower limb.

Joint injury. There are three principal types of joint injury—(1) sprain or strain, in which the ligamentous and tendinous structures around the joint are stretched and even lacerated; (2) contusion, in which the cartilaginous surfaces of the opposing bones in the joint are driven forcibly together; (3) dislocation, in which the articular surfaces are separated from one another; in this last injury the ligamentous capsule of the joint must be torn to allow the accident to occur. Joint strength may be classified anatomically under three heads—(1) ligamentous, due to the ligaments binding the bones together; (2) osseous, due to the shape of the bones forming the joint; (3) muscular, due to the muscles surrounding the joint. Ligamentous strength predisposes to sprains, osseous to contusions, and muscular to dislocations. A joint is frequently saved from injury in consequence of the relative weakness of a bone near it. The ankle joint is saved by the weakness of the fibula, the wrist joint by the weakness of the radius, the sterno-clavicular joint by the weakness of the clavicle; the fracture of the bone preserves the joint from injury. The tonicity of the muscular structures around a joint often prevents a dislocation, the patient being prepared for the violence to which his joint is subjected. The osseous strength of a joint will depend very much on the position of the limb at the time of the accident.

When a joint is sprained or contused there is effusion into it and into the structures around it. In such cases accurately applied pressure will prevent effusion, and along with gentle passive exercise and rubbing will prevent subsequent stiffness. When a joint is dislocated it is of importance to restore the bones to their normal position as soon as possible after the accident. Within the last few years, in several dislocations, the treatment by extension of the limb and forcible pressure of the bones back into their normal position has been given up, and a method of treatment at one time in use in the French schools has been revived by Dr Bigelow of Boston, Mass., who has pointed out that with less force and therefore less injury a dislocated joint may be reduced by manipulation. The great principle at the root of this treatment is to manipulate the limb so as to cause the dislocated bone to pass back into its normal position by the same path by which it left it. In compound dislocations the same precautions must be attended to as in compound fractures.

II. Process of Repair.

After an injury certain changes take place, which, if kept within bounds, terminate in repair, in other words, in a restoration of the injured part to a condition as nearly as possible normal. When the injury is severe the restoration may fall far short of the normal. The recovery may take place with very little pain or discomfort even in severe injuries. Frequently, however, as the result either of improper treatment on the part of the surgeon or of feebleness on the part of the person injured, local uneasiness and a general feverish condition arise, which interfere with the healing. When these evil results follow, a local death of tissue in a greater or less degree is observed. **Forms of local death.** Three forms of local death have been described—(1) suppuration or the formation of pus, (2) ulceration, or the formation of an ulcer, (3) mortification, or the formation of a slough. These three processes run imperceptibly into one another. They are not distinctly separable from one another, and they very frequently occur together. It is to be noted that the process of repair and the local death which interferes with a painless repair differ only in degree. As a general rule, in the truly subcutaneous wound of tissue, be it the soft parts or bone, the changes that take place ending in its repair are simple and uncomplicated; it is in the open wounds of the soft parts and in compound fractures of bone that complications arise.

Repair in subcutaneous wound. In order to understand this process, it will be best to take a simple injury, such as a clean cut. As the result of the passage of an even the sharpest knife through the tissues a microscopic laceration along the line of the incision must occur. The skin, subcutaneous fat, fascia, and muscle are divided. These parts being vascular, bleeding takes place from the cut vessels. Let us suppose that the bleeding has ceased, and that the surfaces and edges of the wound are not brought into contact. The retractile power of the tissues, when they are divided, necessarily produces a trench-shaped gap. If the sides of this gap are watched a weeping of a straw-coloured fluid will be observed, which, when examined under the microscope, is seen to have corpuscles floating in it. The fluid is the liquor sanguinis of the blood, and the corpuscles are the blood corpuscles. In the blood as it circulates throughout the vessels in the body, the yellow or red blood corpuscles are greatly in excess of the white. In this fluid the white blood corpuscles are very numerous. Careful observation, with the aid of a sufficiently powerful microscope, will show the formation of fine fibrils of a solid substance, which gradually extend over the field; this fibrillation takes its start from the white blood corpuscles. The effusion has coagulated. A soft solid—fibrin—is formed, which gradually contracts, and a clear fluid escapes; this is the blood serum. To return to the wound,—in consequence of the injury the smaller blood-vessels dilate, their walls are thinned, and a stasis or stoppage of the flow of blood within these vessels takes place. The stasis is caused by the injury to the vessel walls, rendering the blood corpuscles more adhesive. The circulation is going on in the vessels beyond the area of stasis. The blood in a state of stasis acts as an obstruction, and consequently there is an increased pressure on the inner surface of the thin walls. As a result the fluid part of the blood or liquor sanguinis and the corpuscular elements of the blood escape into the tissues and on to the surface of the wound. On this surface and in the tissue next the surface a clotting takes place, and fibrin is formed. The surface of the wound becomes glazed, and as the fibrin contracts the blood serum oozes out upon the wound surface and escapes. The glazed surface then becomes vascular; new blood-vessels are formed in it, and through these a circulation is set up continuous with the circulation in the blood vessels around. If the surfaces of the gap are now brought into gentle contact, the blood vessels on the two surfaces will unite. At first the uniting tissue is very succulent and vascular, and further changes must occur before the uniting

medium is consolidated. This is effected by the formation of fibrous tissue in the deeper parts of the uniting medium and by the formation of epithelial tissue in the more superficial parts where the skin is divided. Along with these changes the uniting medium becomes less vascular, and a linear scar is the result.

This is the case of an incised wound in which the surfaces are not brought at once into contact. If, however, this is done, the same changes take place, and in a small wound no untoward results need follow. But in a wound of some size there is danger in bringing the edges of the wound into contact. In consequence of the difference in the retractile power of the different tissues that are divided, it may be impossible to bring the deeper parts into accurate contact. The patient will complain of local pain, accompanied by a throbbing sensation, showing that an accumulation of serum has taken place. If a stitch is removed, the serum will escape and the local uneasiness disappear. If, however, no relief is given, the retained serum, pressing upon the surrounding tissues and acting as a foreign body, will cause effusion of more serum. The white blood corpuscles will pass from the vessels in large numbers, will die, and practically a cemetery of white blood corpuscles will be formed; if a stitch is then removed a creamy fluid escapes. This fluid is termed "pus." Once the tension is relieved, the local uneasiness disappears; but the wound cannot then heal by primary union. The walls of the cavity must again become glazed, vascularization must take place; and, as the walls of the cavity gradually come together by contraction, fibrous tissue is formed. This is *union by second intention*.

Abscess and pus formation. The collection of white blood corpuscles floating in the effusion and eventually forming pus is termed an *abscess*. Pus may also form amongst the tissues after a blow or other injury. As the result of a blow a certain area of tissue becomes congested, and effusion takes place into the tissues outside the vessels; the effusion coagulates and a hard brawny mass is formed. This mass softens towards the centre; and if nothing is done the softened area gradually increases in size, the skin becomes thinned over it, the thinned skin loses its vitality, and a small slough is formed. When the slough gives way, the pus escapes. Such shortly is the history of an acute abscess under the skin, and the explanation generally given is that a local necrosis or death of tissue takes place at that part of the inflammatory swelling farthest from the normal circulation. When the dying process is very acute death of the tissue occurs *en masse*, as in the core of a boil or in the slough in a carbuncle. Sometimes, however, no such evident mass of dead tissue is to be observed, and all that escapes when the skin gives way is the creamy pus. In the latter case the tissue has broken down in a molecular form; in the former case it has broken down *en masse*. After the escape of the core or slough along with a certain amount of pus, a cavity is left, the walls of which become lined with lymph. The lymph becomes vascular, and receives the name of granulation tissue. The cavity heals by second intention. Pus may accumulate in a normal cavity, such as a joint or bursa. It may also be met with in the cranial, thoracic, and abdominal cavities. In all these situations, if the diagnosis is clear, the principle of treatment is free evacuation of the pus, and in joints and in the peritoneal and pleural sacs washing out the cavity at the time of opening, free drainage, and careful antiseptic treatment during the subsidence of the inflammatory process. The tension is relieved by letting out the pus. If the after-drainage of the cavity is thorough the formation of pus ceases, and the serous discharge from the inner side of the abscess wall gradually subsides; and as the cavity contracts the discharge becomes less and less, until at last the drainage-tube can be removed and the external wound allowed to heal. The large collections of pus which form in connexion with disease of the vertebræ in the cervical, dorsal, and lumbar regions are also now treated by free evacuation of the pus, with careful antiseptic measures. In all cases care should be taken to make the opening as dependent as possible in order that the drainage may be thoroughly efficient. If tension occurs after opening by the blocking of the tube, or by its imperfect position, or by its being too short, there will be a renewed formation of pus.

Ulceration. When a considerable portion of tissue dies in consequence of an injury, the death taking place by gradual breaking down or disintegration, the process is termed *ulceration*, and the result is an ulcer. As long as the original cause which formed the ulcer is at work, the gap in the tissues becomes larger and larger. Suppose that the ulcerative process is going on and the ulcer is spreading. The ulcer is then painful and the parts around are inflamed. Remove the cause by appropriate treatment and the necrotic process ceases, the shreds of tissue are cast off, the ulcer gradually cleans, the inflammation subsides, the pain disappears, the ulcer becomes a healing ulcer. The surface of the gap becomes glazed, and those changes take place in it which have already been described as occurring in an open wound. The gap gradually contracts in size. Round the edges cicatrization occurs, leaving a scar or cicatrix. Within the last few years the process of cicatrization has been hastened by planting on the granulation tissue small grafts of epidermic tissue in the manner already described (p. 681). There can be little doubt that the growth of an ulcer, as well as the disintegrating process which precedes its formation, is closely associated with the multiplication of low forms of plant life in the decaying tissue. By destroying these organisms with some powerful antiseptic the destructive process may be checked. Since these organisms live on decaying matter, they are termed "saprophytic." The healthy tissues are antagonistic to their growth, and any treatment which renders the tissues around the gap healthy will interfere with their further development. The entrance of those organisms into a wound made by the surgeon, if they find in it a suitable soil for their development, is undoubtedly also a fertile cause of suppuration in wounds. But it must be distinctly remembered that any means which are adopted to keep the injured tissues in a healthy condition interferes with the growth of these saprophytes as directly as if the surgeon used some antiseptic substance which destroyed them. What relation obtains between a local necrotic process, such as the formation of a boil with its central slough, situated necessarily in the first instance under the skin, or the equally necrotic process, the formation of pus in a subcutaneous abscess, and these low forms of plant life? There can be no doubt that by the injection into the tissues of a powerful irritant these necrotic changes can be induced without the intervention of organisms. Professor Ogston and Mr Watson Cheyne have also shown that micrococci are present in the great majority of acute subcutaneous necrotic inflammations, as they are commonly met with in the human body. Here the question at present rests. The opinion of the present writer is that in all probability they are the cause of the necrotic process. It is not asserted that they are the cause of the primary inflammation, which need not go on to necrosis; but the probability is that they find in the inflamed area a nidus for their growth and development. It is not known how they cause it, whether by direct action upon the tissues or by irritating products formed during their growth. The organisms described by Ogston and Cheyne have a life history and require conditions for their existence and development different from those demanded by the saprophytic organisms already described. To reach the subcutaneous area of inflammation they must pass by the blood-stream, and must be able to exist in the living blood. They are probably associated with the infective class of organisms. In some suppurations at the present moment, such as acute suppurative periostitis, the formation of pus under the periosteum connected with bone, a suppuration within the medullary cavity of a bone called osteomyelitis, and in acute ulcerative endocarditis, the organisms met with are undoubtedly infective. We do not know exactly how they enter the blood stream, but we know that they can live in it, and that the occurrence of these diseased conditions is undoubtedly a local effect closely connected with blood-poisoning.

A portion of the body may die in consequence either of an intense inflammation or of a cutting off of the blood-supply. Besides these two distinct varieties there is a great intermediate group of cases in which both causes may be at work. A comparatively slight injury affecting a portion of the body imperfectly supplied with blood may give rise to an inflammatory condition which in a healthy part would be easily checked, but which in consequence of imperfect nutrition may end in mortification. Whilst the pressure of a tight boot in an old person with atheromatous vessels can give rise to mortification, the same pressure in a healthy person would give rise only to an evanescent redness. Frost-bite is a localized death of a portion of the body which has been exposed to prolonged cold. It may attack the fingers or toes. The death may occur directly without any intermediate reactionary inflammation, or it may follow an excessive reaction. The rule of treatment in all cases of gangrene in which there is a tendency to death is to keep the part warm by layers of wadding, but to avoid all methods which hurry the returning circulation, because any such increase would be followed by excessive reaction, which in its turn in a part already weakened would be followed by secondary death. When the part is dead, envelop it in antiseptic wadding to prevent putrefaction; wait until the line of demarcation between the living tissues and the dead part is evident, and then, if the case permits, amputate at a higher level. In spreading gangrene in which sepsis is present, and in which no line of demarcation forms, the best chance for the patient—at best a poor one—is to amputate high up in sound tissues. In these cases the blood is generally poisoned, and if the patient recovers from the primary shock of the operation a return of the decaying process may attack the stump, and carry him off. Mortification or gangrene.

III. DISEASES.

1. *Diseases of Blood vessels.*

An aneurism, in so far as we have to deal with it at present, may be defined as a sac communicating with the lumen of an artery. Aneurism. The sac-wall may be formed of one or more of the arterial coats which have become dilated. The tissues around, being condensed and being more or less adherent to the sac wall, strengthen and support it. The dilatation of the arterial coats is generally due to a local weakness, the result of disease. The diseased condition is almost always a chronic form of inflammation, to which the name *atheroma*

is given In some instances the local weakness may be due to an injury bruising or lacerating the vessel and injuring its internal coat When an artery is wounded and when the wound in the skin and superficial structures heals, the blood may escape into the tissues In this case it displaces the tissues and by its pressure causes them to condense and form the sac wall The coats of the vessels, more especially when they are diseased, may be torn from a severe strain, and the blood will then escape into the condensed tissues forming the sac-wall When one or more of the vessel coats form the sac there results what is called a *true aneurism*, in those instances in which the sac wall is formed by the condensed tissues around we have a *primary false aneurism*, when a true aneurism bursts and the blood escapes into the tissues around it, as sometimes occurs in deep seated aneurisms, giving rise to secondary localized accumulation, the term *secondary false aneurism* is used In both varieties of false aneurism the swelling is more diffuse and the pulsation as a rule is less marked than in the true aneurism

The blood in an aneurism is at first in a fluid state, and at each beat of the heart a certain amount passes into the sac, causing its expansion In all aneurisms there is a tendency to coagulation of the blood, and a blood-clot is deposited in a laminar form on the inner surface of the aneurismal sac In some instances this laminar coagulation by constant additions gradually fills the aneurismal cavity The pulsation in the sac then ceases, contraction of the sac and its contents gradually takes place, the aneurism is cured On the other hand, if the blood within the sac remains fluid, the aneurism will gradually increase in size, the tissues over the aneurism and the sac wall will become thinned, and at last give way, and death occurs from hæmorrhage

Treatment of true aneurism

In the treatment of true aneurism the great principle is to encourage coagulation in the aneurismal sac This can be done by lessening the force of the circulation generally or locally The general force of the circulation can be lessened by low diet, rest in bed, avoidance of all causes of vascular excitement, and by the administration of large doses of iodide of potassium The force of the circulation can be decreased locally and temporarily by the application of a ligature to the artery between the aneurism and the heart or by the application of pressure upon the main vessel at a convenient point between the aneurism and the heart The general treatment is available in all cases The local treatment by operation or by compression is only available in those instances in which the aneurism is so situated that the blood-vessel can be compressed or ligatured, as in aneurisms of the head and neck or of the extremities In certain aneurisms in the lower part of the neck and upper part of the thorax, in which a ligature cannot be applied between the aneurism and the heart, the blood flow through the aneurismal sac has been diminished by the application of a ligature to one or more of the main vessels on the distal side of the aneurism The blood-supply to the parts beyond the aneurism being thus cut off, the immediate effect is increased pressure on the aneurismal sac, but, since the parts accommodate themselves to altered circumstances, as the collateral blood vessels increase in size, becoming the main vessels of supply to the parts beyond, the original channel becomes of secondary importance, the result being a diminution in the size of the main vessel and diminished blood in the sac, encouraging coagulation and contraction of the aneurismal sac Practically the same effect has sometimes been obtained in a permanent way, as in cases of rapidly increasing aneurism of the subclavian artery in the root of the neck by amputation of the upper extremity at the shoulder joint And within the last few years, in popliteal aneurism, the same thing has been done temporarily by the application of an elastic bandage to the limb from the foot upwards to the popliteal space, emptying the blood-vessels below the knee, and in this way cutting off the blood supply temporarily The application of the elastic bandage is continued up the thigh, care being taken not to make firm pressure with the bandage as it passes over the aneurism behind the knee joint, so that the sac may not be emptied of blood If the sac were emptied, the object in view would be defeated, because there would be no blood in the sac to coagulate The continuation of the bandage in the thigh above the aneurism is practically a compressing agent applied to the artery on the proximal side of the aneurism The rationale of this treatment of popliteal aneurism, due to Dr Walter Reid of the British navy, may, if this explanation is correct, be said to owe its success to the fact that in it we combine the two great principles which check the blood pressure locally, *i e*, a cutting off of the blood-supply beyond the aneurismal sac and compression on the main vessel on the proximal side It is to be noted that all these different means of checking the blood-pressure within the aneurismal sac are temporary in their action The temporary arrest by compression, the equally temporary arrest by the application of a ligature, in the latter case the collateral anastomosing circulation taking the place of that of the main trunk which has been ligatured, start the process of coagulation within the sac, and, the process being once started, complete consolidation gradually takes place Although these methods of treatment are principally of value in true aneurism, they are also to a certain extent useful in secondary false aneurism In primary false aneurisms, on the other hand, we have to deal with a wounded vessel in which the blood, instead of being poured out externally, is poured into the tissues, and is practically a (chronic) bleeding point, the principle of treatment is to open the sac, turn out the clots, and ligature the artery above and below the bleeding point

Diseases of veins

The veins are liable to inflammation (*phlebitis*) When this occurs the blood in the vein is liable to coagulation, forming a clot or thrombus, which, if displaced from its original position, either makes its way as an embolus towards the heart and is there arrested, or passes through the cavities of the heart into the lungs, there sticking and giving rise to lung symptoms If the thrombus is formed in the hæmorrhoidal plexus, it passes as an embolus by the portal system into the liver If it is formed in the left side of the heart, it may pass into the large vessels at the root of the neck and reach the brain, giving rise to symptoms of brain disease The thrombus may be formed apart from inflammation of the vein wall in consequence of diseased states of the blood, as in gout and rheumatism, or it may form in consequence of stagnation of the blood-current due to slowing of the circulation in various wasting diseases When a thrombus forms, absolute rest in the recumbent posture is to be strictly enjoined, the great danger is embolism or the displacement of the clot from its original position Hot fomentations in the early stages and belladonna ointment when the condition becomes sub-acute are the best local applications The desire is to promote absorption of the clot The veins in the lower extremity and in the hæmorrhoidal and spermatic plexus are liable to dilatation The condition is termed *varix* The veins dilate with tortuosity, the valves become incompetent, and the condition is apt to spread In the lower extremity the primary cause may be an injury or some obstruction at a higher point General laxity of the tissues predisposes to the condition, occupations which necessitate much standing and alternation of heat and cold also act as predisposing causes The treatment consists in giving the dilated vessel support by means of an elastic bandage or stocking When the condition is local and gives discomfort, the vessel may be ligatured at various points so as to cause its obliteration This operation should not be undertaken rashly, and should only be performed if the case is an aggravated one, since it is by no means devoid of risk In the hæmorrhoidal plexus the disease is termed *internal hæmorrhoids* or *piles*, many operations are performed for this condition, but in the great majority of cases the careful use of purgatives and the administration of cold water injections into the rectum will relieve the condition The dilated veins often ulcerate and give rise to bleeding piles, here an operation is often called for, because the persistent loss of even small quantities of blood is apt to result in chronic anæmia The enlargement of the spermatic plexus is termed *varicocele*, and almost always occurs on the left side The use of a suspensory bandage and cold bathing should first be tried, if the disease persists, it is often associated with mental depression, and an operation—ligature at several points of the dilated vessel—should be performed The disease may be associated with atrophy of the testicle on the same side, and this liability aggravates the mental condition and encourages the surgeon to operate Inflammation of the lymphatic vessels in the lower limbs is often associated with inflammation of the veins in the female after delivery, giving rise to the various forms of *white leg* Acute inflammation of the lymphatic vessels and glands is also associated with poisoned wounds, and has already been alluded to in connexion with injuries The use of hot fomentations and careful elastic pressure with rest are prescribed for treatment

2 *Diseases of Bone.*

Bone diseases

Attention has already been directed to one form of injury to a bone, viz, fracture A word may now be said about inflammation of a bone and its results As a typical instance we will take a long bone, consisting of a shaft and two extremities The walls of the shaft consist of dense bone, the extremities of cancellated tissue The shaft of the bone is hollow, and filled with medullary tissue In the fully developed bone the extremities alone are tipped with cartilage, in the extremities of the bones of a growing person there are also layers, termed the *epiphyseal cartilages* The bone is surrounded by a fibrous membrane termed the *periosteum* This membrane is richly supplied with blood vessels, which ramify through it and pass, along with lymphatic vessels and nerves, from it into the Haversian canals in the dense bone forming the shaft. The deeper layers of the periosteum consist of osteoblastic cells, which also line the Haversian canals In the undeveloped condition these cell elements take an active part in the growth of the bone as regards its breadth, the epiphyseal cartilages taking an active part in its growth as regards its length The medullary tissue in the cavity of the bone is supplied by the nutrient artery, the cancellated tissue forming the extremities receives its blood-supply partly from the nutrient artery and partly from vessels passing indirectly from the periosteum When a bone is injured—as happens, for example, in a severe bruise—the blood vessels in the periosteum and in the Haversian canals become congested, effusion of liquor

sanguinis and migration of the white blood corpuscles take place, and a severe gnawing pain is felt at the seat of the bruise. The pain is severe because the effusion cannot escape. It collects under the periosteum and in the Haversian canals. The cell elements in these situations are irritated, and cell proliferation takes place. The periosteum becomes thickened, and if the tension continues suppuration may occur between the periosteum and the bone. The periosteum is raised from the bone, the blood-vessels passing into the Haversian canals are obliterated or torn across, and the outer layers of the hard dense bone, their sources of nutriment being cut off, die. The extent of the necrosed tissue will depend upon the extent of the suppurating area; if the suppurating area includes the nutrient artery within its range, nutriment being then cut off from the medullary tissue from which in part the deeper layers of the shaft of the bone are supplied with blood, death of the whole thickness of the shaft of the bone may occur. As already stated, the most acute forms of suppurative periostitis and suppurative osteomyelitis are infective diseases, the suppuration in them being due to the presence of a micrococcus. If after an injury the primary inflammation is relieved by fomentations, leeching, or incisions, suppuration may be prevented; or even if, after suppuration has occurred, free incisions are made to allow the pus to escape, the periosteum may assume its normal position, and the area of necrosis be limited or necrosis be prevented altogether. After a portion of the shaft of the bone dies, the necrosed area is gradually absorbed; but, if the area is of considerable size, and more particularly if sepsis occurs, the dead part is gradually separated from the living, and after a time it becomes loose, and as a rule has to be removed by operation. If the inflammation, acute in the first instance, becomes sub-acute, or if it is sub-acute from the first, then, instead of suppuration, the effusion under the periosteum coagulates, whereupon lymph is formed, the proliferating osteoblastic cells in the lymph take up their normal function, and new bone is made. This mass of new bone is termed a *node*. In the Haversian canals the osteoblasts there forming bone will render the bone tissue more dense and ivory-like in consistence, to which the term *sclerosis* is applied. In some cases the osteoblastic cells in the Haversian canals, instead of forming bone, feed upon the original bony tissue which constitutes the walls of the canals. The Haversian canals becoming enlarged, the result is a lessening of the amount of inorganic matter in the area affected, and a cancellation of the hard bone takes place. This condition is called *rarefying ostitis*. The rarefaction of the dense bone may persist, or the process may stop, the osteoblasts again forming bone and the rarefied area becoming sclerosed. In the cancellated tissue in the extremities of the long bones, and in that which forms the mass of the short bones, such as the vertebræ, the tarsal and the carpal bones, the inorganic matter compared with the hard bone is relatively in smaller amount than the organic matter filling the cancellæ. Here as a result of injury the thin lamellæ of bone may be cut off from their blood supply, and death take place. If the process is acute, an area of cancellated tissue will die, and be separated from the surrounding living tissue as in the hard bone. In consequence, however, of the quantity of organic matter, death may take place in a molecular form, more nearly allied to the process of ulceration in the soft parts. This condition is known as *caries*. If the inflammatory process in cancellated tissue is sub-acute, instead of a molecular death, sclerosis of the cancellated tissue occurs. When the cancellated tissue is the seat of inflammation, in consequence of its close connexion and intimate anatomical relations with the articular cartilages, they in their turn become implicated, and we have then to deal with disease of the joint. In all cases in which incisions are made to relieve tension under the periosteum, or in which portions of bone are removed to relieve tension in the shaft or in the medullary cavity of a bone, or in which incisions are made to check the progress of inflammatory action in the cancellated tissue, strict antiseptic precautions must be taken to prevent sepsis occurring in the wound.

3. *Diseases of Joints.*

Structure of joint. A joint is a complicated organ, and its integrity depends upon a healthy condition of the bones which form it, of the articular cartilages which cover the ends of the bones, and of the synovial membrane which supplies the synovial fluid that lubricates the joint. These different structures are closely associated anatomically and physiologically, and disease beginning in any one of them will assuredly, unless checked, gradually extend to the others. The cartilage covering the ends of the bones receives its blood supply mainly from the bone, and is also to a certain extent supplied at its edges by the synovial membrane. The cartilage being in itself non-vascular, disease does not commence in it; the majority of joint diseases commence either in the synovial membrane or in the bone, as a general rule they begin with some slight injury of the joint. These injuries consist of strains or twists (of the joint) on the one hand and jarring or contusion on the other. In the latter case the elastic cartilage lessens the force of the contusion.

When a joint is strained, the ligaments binding the bones together are stretched and the synovial membrane becomes inflamed. Sprain.
Consequently effusion takes place into the joint, which becomes swollen and painful on pressure. Any movement of it is painful, and all the muscles around it are rigid. In a healthy person appropriate treatment—rest, hot fomentations, and gentle elastic pressure—will cause the fluid within the joint to be gradually absorbed, after which the joint can be restored to its normal condition. When the inflammation becomes sub-acute the pain disappears, and unless the joint is kept quiet by appropriate splints the condition is very apt to become chronic; that is, the joint becomes swollen and the movements are restricted. This condition is most persistent, and prolonged rest, along with counter-irritation by blistering or by the application of tincture of iodine, is necessary before the effusion subsides. The joint may remain weak for the rest of the patient's life. Fibrous adhesions may form and prevent free movement. A joint in such a condition is always liable on the slightest injury to have a return of the effusion in an acute or sub-acute form. These are the chief consequences of a strain in a healthy person. In a weakly person the primary strain may entail a very different result. The synovial membrane may undergo gelatinous or pulpy degeneration, and, although it is improbable that this condition is associated with the tubercular diathesis in all cases, there can be no doubt that in very many the degeneration of the synovial membrane is tubercular in character. The tubercle bacillus has been found in the thickened membrane. A joint in this condition swells; the enlargement, although it may be due in part to effusion into the cavity of the joint, is mainly caused by the thickening of the synovial membrane, which has a peculiar doughy semi-elastic feeling. The movements of the joint are restricted, though little pain is complained of. If it is an upper limb the patient will not use it; if a lower limb he will walk with a distinct limp. The disease is a chronic one, and the joint may remain in this condition for months. Rest, elastic pressure, and blistering may check the progress of the disease, but as a rule, sooner or later, and very often as the result of some slight injury, a change takes place. On the one hand, the effusion within the joint, instead of being serous, becomes sero-purulent and even purulent, owing to the formation of pus within it. If the joint is an important one, inflammatory fever is set up; the joint becomes intensely painful on the slightest movement, and unless incisions are made to allow the pus to escape it passes gradually into a state of complete disorganization. The cartilage softens and breaks down, so that gradually the cancellated bone underneath is exposed. A similar change takes place in the opposing cartilage. It is destroyed in its turn and the ligaments binding the bones together are softened and lose their elasticity, so that the joint can be moved in abnormal directions. A grating sensation can be felt when the cancellated bony surfaces are rubbed together. Along with these changes within the joint, foci of inflammation form in the soft tissues around it. These inflammatory areas suppurate; the abscesses burst into the joint; the skin over them gives way; and communication is established between the external air and the cavity of the joint. Through this channel the causes of putrefaction reach the cavity, and complete disorganization of the part accompanied by sepsis occurs. Should the joint be an important one, a condition termed *hectic* is set up. If the discharge is allowed to continue, a gradual wasting takes place, which sooner or later ends in the death of the individual, unless the surgeon either relieves the tension by free incisions, or excises the joint, or amputates the limb. After disorganization has occurred, if the inflammatory process ceases, anchylosis of the joint may result. But, if the joint is freely drained and kept at rest, the inflammation will subside, and the granulation tissue on the two opposing surfaces will unite and a fibrous formation take place. The process may stop there, or the fibrous tissue may be gradually transformed into bone. Osseous union has taken place between the bones forming the joint. In many cases this is what the surgeon aims at, and it is of great importance to keep it constantly in view and to place the joint in such a position that, if anchylosis does occur, the limb may be as useful as possible. This result is only attained after prolonged treatment, and, if the patient's strength is unequal to it, it will be necessary to excise the affected joint or to amputate the limb. Suppuration sometimes occurs within a joint without any previous pulpy degeneration of the synovial membrane, either as the result of a wound or from septic inflammation secondary to pyæmia, or in consequence of a very acute simple synovitis resulting from excessive tension within the joint. When the synovial membrane is affected with pulpy degeneration the vitality of the cartilage at its edges, where it joins the synovial membrane, may be interfered with; the thickened synovial membrane, by encroaching on the articular cartilage, gradually by pressure alters the nutrition of the cartilage so that it disintegrates and breaks down, and when it is destroyed disorganization of the joint ensues, as already described. Should the disease assume this form, if care is taken, and if the joint is kept quiet, suppuration within it need not necessarily take place. The inflammation may assume a sub-acute type and fibrous anchylosis occur.

Contusion. When a joint has been severely contused, separation of the cartilage from the bone occurs; effusion then takes place between the cartilage and the bone; the cartilage is cut off from its nutrient supply, and, unless the joint is kept at complete rest, unless the effusion is absorbed, the cartilage will sooner or later become necrosed. The necrosed cartilage will give way; the bone beneath will be exposed; and, if the irritation is kept up, effusion, at first serous but soon becoming purulent in consequence of the tension within the joint, will take place. Changes follow in the opposing cartilage, which has been itself bruised by the primary jar, and perhaps even separated from the bone beneath. It will in its turn necrose, and the bone will be exposed, suppuration taking place within the joint. The synovial membrane will become diseased, the ligaments softened, and the evil sequence of events already described will ensue. A joint affected in this way is easily recognized from one in which the synovial membrane is primarily affected by the absence of swelling and by the intense pain. In the early stages complete rest should be obtained by affixing a weight to the affected limb. This, by setting up between the opposed and injured cartilaginous surfaces a condition of negative pressure, will tend to check the disease. But if this plan of treatment does not soon cause a subsidence of the pain, actual cautery must at once be resorted to. Contusion in which the cancellated bone is injured at some distance from the cartilage is most commonly met with in young people, in whom the extremities of the bones are not fully developed. In them the epiphyseal cartilages are richly supplied with blood for the performance of their physiological function, the formation of bone, and a comparatively slight injury may cause inflammation to be set up in the bone immediately in contact with the epiphyseal cartilage. As in the synovial membrane when it is affected with pulpy degeneration, this disease may be occasionally non-tubercular in character; but in the majority of cases, more especially when the primary injury is very slight, the disease assumes the tubercular type and tubercle is deposited. In such cases the symptoms are often very insidious; the young patient complains of some slight uneasiness, or the first thing to be noticed is a limp in walking when a lower limb is affected. In the case of an upper limb the patient will avoid moving the affected joint. As there is no external swelling, the disease may be overlooked in its early stages; but, if it is suspected, and if the affected limb is kept at rest, the inflammation will subside and recovery ensue. On the other hand, if the patient is allowed to use the limb, even in an imperfect way, the tubercular area may extend and the articular cartilage become affected. The articular cartilage does not in that case receive its proper nourishment; it disintegrates, breaks down, and the disease attacks the joint. Into this last tubercular matter escapes and suppuration occurs, resulting sooner or later in disorganization of the joint.

In recent years a useful limb has often been saved by excision of the affected joint. In the early stages the disease may subside under appropriate local treatment, such as counter-irritation, rest, pressure, assisted by constitutional treatment, such as tonics, fresh air, and careful dieting. By these means an operation may be avoided, and in applying such treatment it must be remembered that, while the disease itself may subside, the joint as an organ may

Anchylosis. be irretrievably damaged; it may become anchylosed. If anchylosis occurs in a flexed position of the hip or knee joints, the limb will be useless for progression, and an operation will be necessary in order to straighten it. In the ankle joint, if anchylosis occurs with the foot in an extended position, the patient will not be able to put his heel to the ground, and an operation will be necessary to bring the foot at right angles to the leg. Do not interfere with an anchylosed joint in the lower limb if it is in good position. If the shoulder joint becomes anchylosed after disease, the sterno-clavicular and acromio-clavicular joints take up to a great extent the function of the anchylosed shoulder. In the elbow, in whatever position the joint becomes anchylosed, the arm loses much of its usefulness, and excision of the joint is performed in order to get a movable elbow. In the wrist it may be necessary to operate for anchylosis; but as a rule, if the fingers are mobile, the anchylosed wrist does not interfere to any great extent with the usefulness of the hand.

4. *Venereal Diseases.*

Relations of venereal diseases. Three distinct affections are included under this term—gonorrhœa, chancroid, and syphilis. At one time these were regarded as different forms of the same disease; and, though gonorrhœa is now generally held to be quite distinct from the other two, there are not wanting eminent authorities, including Mr Jonathan Hutchinson, who are inclined to look upon chancroid and syphilis as essentially one and the same disease. The present writer believes that gonorrhœa, chancroid, and syphilis are three distinct diseases, due to separate causes, which have nothing in common except their habitat. The cause in each case is a specific virus, probably a micro-organism. In the case of gonorrhœa the virus attacks mucous membranes, especially that of the urethra; in chancroid mucous membranes and the skin are affected; in syphilis the whole system comes under the influence of the poison. Gonorrhœa and chancroid correspond to the process of septic intoxication. The organisms on implantation set up a local disturbance, and the products of this fermentative process pass into the system and give rise to constitutional effects; but the organisms themselves do not pass into the system generally. In syphilis, on the other hand, there is a true infective process: the organisms pass into the general circulation and live and multiply wherever they find a suitable nidus. The joint affection commonly called "gonorrheal rheumatism," which sometimes follows gonorrhœa, is in all probability an infective condition. If this is true, then in these rare cases gonorrhœa is infective. The chancroid poison may pass into the lymphatics and cause inflammation of the lymphatic glands in the groin, giving rise to *chancroidal bubo*. These clinical facts are undoubtedly opposed to any generalization such as that laid down above, and it is right to note them; but the general comparison between gonorrhœa and chancroid as non-infective and syphilis as distinctly infective in its character holds good in the great majority of cases. A further study of these quasi-infective varieties of gonorrhœa and chancroid must undoubtedly throw light upon the physiological classification of pathogenic organisms. These three affections are generally acquired as the result of impure sexual intercourse; but there are other methods of contagion, as, for example, when the accoucheur is poisoned whilst delivering a syphilitic woman, the surgeon when operating on a syphilitic patient. An individual may be attacked by any one or any two of the three, or by all of them at once, as the result of one and the same connexion; but they do not show themselves at the same time; in other words, they have different stages of incubation. In gonorrhœa the disease appears very rapidly, so also in chancroid, the first symptoms commencing as a rule three or four days after inoculation. It is very different, however, with syphilis. Here the period of incubation is one rather of weeks, the average length being twenty-eight days, though it may vary from one week to eight. The length of the period of incubation, therefore, is the great primary diagnostic in the case of syphilis.

Syphilis. Syphilis is an infective fever, and its life history may be best considered by comparing it with vaccinia. A child is vaccinated on the arm with vaccine lymph. For the first two or three days nothing is observed; but on the fourth day redness appears, and by the eighth day a characteristic vaccine vesicle is formed, which bursts and frees a discharge, which dries and forms a scab. If on the eighth day the clear lymph in the vesicle is introduced at another point in the child's skin, no characteristic local effect follows. The system is protected by the previous inoculation; this protection will last for some years, and in certain cases for the rest of the patient's life. We have here, then, exposure to a poison, its introduction locally, a period of incubation, a characteristic local appearance at the seat of inoculation, a change in the constitution of the individual, and protection from another attack for a variable period. So with syphilis. The syphilitic poison is introduced at the seat of an accidental abrasion either on the genital organs or on any part of the surface of the body. The poison lies quiescent for a variable period. The average period is four weeks. A characteristic cartilaginous hardness appears at the seat of inoculation. If this is irritated in any way, an ulceration takes place; but ulceration is an accident, not an essential. From the primary seat the system generally is infected. The virus is multiplied locally and, passing along the lymphatic vessels, attacks the nearest chain of lymphatic glands. If the original sore is in the genital organs, the glands in the groin are first attacked; if in the hand, the gland above the inner condyle of the humerus; if on the lip, the gland in front of the angle of the jaw. The affected glands are indurated and painless; they may become inflamed, just as the primary lesion may ulcerate; but the inflammation is an accident, not an essential. From the primary glands the mischief will affect the whole glandular system. The body generally is so altered that various skin eruptions, often symmetrical, break out. Any irritation of the mucous membrane is followed by superficial ulcerations, and in the later stages of the disease skin eruptions, pustular and tubercular in type, appear, and in weakly people in severe cases, or in cases that have not been properly treated by the surgeon, syphilitic deposits termed *gummata* are formed. These, if irritated, break down and give rise to deep-seated ulcerations. Gummata may attack the different organs in the body; the muscles, liver, and brain are the favourite sites. Their presence interferes with the functions of the organs, and, if the organ affected is one functionally important in the economy, may cause death. The individual is as a general rule protected against a second attack, although there have been rare cases recorded in which individuals have been attacked a second time.

Treatment of syphilis. Syphilis is treated by many surgeons by giving careful attention to the general health, to diet and regimen and tonics, by placing the patient in the most favourable hygienic circumstances, in the belief that it runs a natural course and has a tendency to natural cure. Special symptoms are treated as they arise. Other surgeons administer small doses of mercury, in the form of grey powder, iodide of mercury, or corrosive sublimate. If the physiological

effects of mercury are observed—tenderness of the gums and a metallic taste in the mouth—this treatment is desisted from and iodide of potassium is administered, mercury being given again when its physiological symptoms have disappeared. Oleate of mercury or mercurial ointment, or mercury with lanoline, is applied to the primary lesion and rubbed in over the enlarged glands. This is continued for six months or a year. In the later stages of the complaint iodide of potassium is the main remedy used. There are therefore two distinct methods of treating syphilis,—the non-mercurial and the mercurial. Both methods have been extensively tried by the present writer, and he believes that the mercurial is infinitely preferable to the non-mercurial method. Recent investigations point to the value of corrosive sublimate as a germicide, and in all probability the good results which follow saturation of the system with mercury are to be explained in this way. It is said by the non-mercurialists that the administration of mercury masks the symptoms. There can be no doubt that the symptoms often appear after the mercury is stopped, but in a modified form, and there is no evidence that the mercurial treatment prolongs the disease. Syphilis has a tendency to natural cure, like all the continued fevers, and along with the administration of mercury careful hygienic treatment must receive particular attention, and often in weakly unhealthy people a long sea voyage is of great value. Any means which causes a free action of the skin, as, for instance, by periodic visits to thermal baths, is of great assistance in eliminating the poison.

Syphilis as commonly met with nowadays is not of so severe a type as it formerly was. One reason often given for this is that mercury was formerly always pushed until its full physiological effects were observed, and that the lowering of the patient's constitution by this severe treatment aggravated the primary complaint. There may be some truth in this explanation, but the principal reason in all probability is that the syphilitic organism does not now find so suitable a nidus or soil for its growth and development as it once did. Syphilis in the United Kingdom at the present moment is in the stage of an epidemic in its decline. This may be looked on as a startling statement, but it is true of syphilis as of all infective diseases. A time must come when the soil is practically worn out, when it becomes so poor that the organism grows only in a stunted form, producing a mild disease, till in time it ceases to grow altogether. It is not asserted that it will necessarily die out, because after lying fallow for a time the soil may recover its power and the disease be revived in a more virulent form, analogous to the luxuriant crop which follows after a period of fallow. Syphilis can be conveyed by the discharge from any syphilitic lesion occurring within two years after the commencement of the complaint. It cannot be conveyed by the normal secretions of the syphilitic person except in the case of the semen, which, impregnating the ovum in the female, causes the fœtus to be syphilitic. Syphilization of the fœtus is followed by syphilization of the mother. The blood of a syphilitic person is infectious for two years after the commencement of the attack. Pure vaccine lymph cannot convey syphilis; if, however, it is mixed with blood it may convey it. No person who has had syphilis should marry until he has been entirely free from the complaint for two, or better still for three, years. If a person marries before this time pregnancy greatly increases the risk to the mother. If there is any suspicion of syphilis the mother should take mercury during the period of pregnancy. It is interesting to note how time has a modifying influence in a case of repeated pregnancies occurring in a syphilitic woman. At first there may be miscarriage in the early stage of pregnancy; after a time abortions in the later stage; there may then be a still-born child; then one born alive but syphilitic; then a child born apparently healthy but soon becoming syphilitic; and ultimately a healthy child is born and remains healthy, showing no evidence of syphilitic disease. The disease has worn itself out. The relation of apparently healthy people born of syphilitic parents to syphilis acquired during the course of their life may explain those remarkable cases of escape from syphilitic infection which constantly come under the observation of the surgeon.

5. *Tumours*.[1]

Cause of tumours. As the result of a local irritation an acute inflammatory swelling may appear. If the irritant is of a severe type the result may be local death. An abscess may form; and, after the pus has escaped or has been evacuated, and after the original cause of the irritation has subsided, the swelling may disappear and the parts be restored to a condition nearly allied to the normal. If the irritant, however, is slight and its action prolonged, a chronic inflammatory swelling of the part may result. Although in many cases with appropriate treatment the induration disappears, in other cases it persists during the life of the individual. The indurated mass in its microscopic characters closely resembles the original anatomical characteristics of the part affected. When, for example, an organ like a gland is the seat of a chronic irritation a general increase in its size takes place. A hypertrophy or overgrowth has occurred, but as a rule the hypertrophied gland is only altered in size; it retains its general shape and functional activity. Occasionally the hypertrophic area is localized, and to a great extent separable from the original gland by a more or less distinct capsule. In the mammary gland, for example, a local hypertrophy may occur, the microscopic characters of which resemble imperfect gland tissue. Between this condition and an adenoid or glandular tumour of the mamma no distinct line of demarcation can be drawn, and the probability is that the adenomatous tumour of the mamma is caused by local irritation. It may be the immediate outcome of a misdirected or excessive functional activity. The great practical difference, however, between it and true hypertrophy is this, that it can only be removed by operation. The adenomatous tumour closely resembles in some of its microscopic characters one of the varieties of epithelioma, of which an increase in the columnar epithelium lining the acini in the gland is the main characteristic. This tumour is not a simple tumour like the true adenoma; it does not grow slowly; it is not encapsulated; the cellular elements in it not only invade the surrounding tissues but tend to pass into the lymphatic vessels and reach the lymphatic glands in the arm-pit, where they grow and form secondary tumours similar in microscopic characters to the original growth. From these secondary foci a further invasion may take place, and the cell elements may reach the blood stream and be caught in the capillaries, forming there new growths, till the patient dies from the general implication of the whole system. This form of tumour has been termed a *malignant adenoma*. While it has originally the microscopic characters of a simple adenoma, if we look to its life history we have in it an excellent example of a malignant tumour. Microscopically it is a stepping stone between the simple and the malignant type of tumour; clinically it is characteristically malignant. The mammary gland is composed of glandular tissue and fibrous tissue. A hyperplasia of the fibrous tissue may occur in consequence of an excessive irritation of the glandular tissue, or apparently a primary increase in the fibrous tissue may occur locally, giving rise to a simple fibrous tumour of the mamma, of which fully developed fibrous tissue is the microscopic characteristic. This overgrowth may become encapsulated and give rise to no symptoms except those referable to its gradual increase in size, and after the gland in which it lies has fulfilled its life history it may stop growing, degenerate, and decay. In the uterus, *e.g.*, those fibrous tumours which occur after the time of child bearing is past, after the uterus has fulfilled its destiny, cease to give any further trouble and are only inconvenient in consequence of their size. Fibrous tissue in the early stages of its development is largely composed of cell elements, and there are tumours, *e.g.*, in connexion with the mamma, which have their prototype in the undeveloped or cellular stage of fibrous tissue. These tumours also are essentially malignant. They grow rapidly, and are richly supplied with thin-walled blood-vessels; the elements of the tumour pass directly into the blood-stream, and reach the capillaries, where they are arrested and where secondary growths like the original growth in their anatomical characteristics are formed, causing the death of the patient.
